W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

DANNALS NEW GENERAL MANAGER!

That's the headline that's coming up next year for League members. Oh, there is an underground movement to upset the well-laid plans of Baldwin and his decreasing number of loyal supporters on the board of directors, but nothing really serious is expected to come of it.

These malcontents are fomenting unrest in several areas, but League headquarters has met that problem before and surmounted it, so it is confident that all will go as planned this time.

Indeed, anyone with a knowledge of the history of the League has to appreciate the years of devotion that Dannals has given and his adherence to maintaining the continuance of tradition. He is in the mold of the outstanding leaders of the past such as. . . by golly, let me think a minute. . . er. . . Huntoon and. . . who was that guy before him?. . . oh yes, Budlong.

We have to remember that Harry stood graciously aside so that Mort Kahn could be elected as Hudson Division director in what turned out to be a major turning point for both amateur radio and for our country. Mort, being a very strong person, took over the League for several years. . . forcibly retiring Budlong, organizing the building fund coup, and initiating the proposed return to pre-WWII licensing in 1963.

We can certainly chalk up the tremendous success of the amateur exhibits at both the Coca-Cola and Venezuelan exhibits at the World's Fair in New York to Harry and his tireless work for the League.

Getting facts on Harry's background is not easy, but my recollection is that he started from a position at a company in New York which made radio equipment and first became the president of the Hudson Amateur Radio Council. From there he was so supportive of the League that the rules prohibiting people making radios professionally from becoming League officers was ignored and he was permitted to run for ARRL director, anyway.

Though the betting was that Harry would be decisively defeated, the vote, if I remember right, was a tie! The opposition, showing poor sportsmanship, accused HQ of voting irregularities and there was talk of trying to initiate envelopes for the ballots which could not be shadow-sorted before the official counting. The vote rerun saw Dannals elected.

Again, we are seeing poor losers in the directors' sweepstakes griping for piddling reasons. Lyndon Johnson showed us that it really didn't matter *how* you won, it was what you did afterward that counted . . . for those of you who are up on your history of LBJ's first election win.

After all, it is the prerogative of HQ to edit the brief histories of the contenders on division ballots, so if almost all of the background of someone who looks like they are not going to be a team player has to be edited out, that's the breaks of the game and it is poor potatoes to beef about it. Many feel that Harry is absolutely right to want to sweep that sort of bickering under the rug where it belongs.

When it comes to running something as big as the League, loyalty and devotion to the HQ mystique are far more important than business experience, so many are hoping that the rather obscure ads for candidates for the General Manager's job will go unnoticed. The League isn't supposed to be a commercial business anyway. . . it is a membership club to promote amateur radio's growth and health. We don't need some big outfit milking every dollar it can from the members, whose average age is increasing and who are heading towards retirement and a fixed, low income.

Amateur radio. . . and the League. . . needs a general manager who is respected. . . one with brains and foresight. . . with a long history of coming up with good ideas and helping the League to prosper. One of the last things we need is a stuffed shirt who is pompous and self-important, complete with jacket and tie. Amateur radio is a hobby. . . it's for fun, despite our ability to provide many services. So our national organization should be headed by a relaxed, technically-expert ham, one who has gone into every aspect of the hobby personally. . . DXpeditioned, has a high DX score . . . into SSTV. . . RTTY. . . and so on. Let's all hear it for Harry.

Remember that Harry is getting on in years. . . and that a union steward doesn't make a lot of money. As General Manager, he might be able to make around $100,000 a year. . . which is in line with the importance of the job. I think that a lot of people would like to see Harry really make it big for a change. And that's certainly a reasonable salary for someone running something as big as the ARRL. That would help make up, too, for all of the years he has put in at no salary as president of the League. It's the least we owe him. . . right?

A few years as General Manager and then he will be able to retire again (I understand he is retiring soon from the union) and live the good life on one of the legendarily-generous League pensions.

POWER STRUGGLE

Yes, there definitely *is* a war going on within the ARRL board of directors. The war is over who will control headquarters, with one side loyal to the power group which has run the League ever since Maxim died in 1936 and the other trying to get the political machine out and replace it with some professionals who, they feel, will run the League for the benefit of the members instead of the clique.

I've always been amused at the blind loyalty of tens of thousands of amateurs to this small group which holds the loyal in utter disdain. Perhaps followers who question not, who

FCC DUMPS PLAIN LANGUAGE!

The FCC has decided to drop its proposed major rewrite of the Amateur Radio Service rules due to overwhelming opposition from the amateur community. In taking the unanimous action on November 12, the Commission noted that, should the amateur community at a later date wish to pursue on its own a general rewrite of the rules, the Plain Language docket might prove helpful.

Although amateurs objected to many specific parts of the Plain Language proposal, it was the general tone of the docket that bothered most hams. The proposed elimination of the five-part Basis and Purpose of amateur radio in section 97.1 of the rules, along with a change in name from the "Amateur Radio Service" to the "Amateur Telecommunications Service," were seen as diminishing the status of the service.

Look for more on the FCC's decision to drop the Plain Language proposal in next month's Kahaner Report.—WB8BTH.

accept everything without question, deserve to be held in such contempt.

Eventually things begin to change and, fight as they do, with dirty deals such as they handed ex-director Miller, the clique is beginning to lose strength. More and more reform-oriented directors have gotten on the board and are sickened by what they've found at HQ. The reformers want to throw out the scoundrels and get in some new blood.

Well, I say, "better the devil you know than the one you don't." The League is doing well, considering the virtually terminal health of the hobby itself. Most of the amateurs I've talked with have a strong death wish for the hobby . . . "we don't need any more hams . . . the bands are already too crowded" . . . and, "we don't want any technical changes . . . we like CW and sideband." Many feel that only Extra Class amateurs should have phone privileges . . . as the ARRL HQ proposed in 1963.

A great many amateurs feel that since the politics of amateur radio is complex . . . and after all, this is *only* a hobby . . . it's better to leave everything to the ARRL. Who should know better than HQ what should be done?

The ad in the November *QST* (page 21) for people interested in the General Manager job which will be open when Baldwin steps down in March was run, apparently, as a sop to the starry-eyed reformers on the board. Little is expected to come of it. Indeed, even though the general membership has no vote in the election of the highest offices . . . General Manager, Editor of *QST*, and President of the League . . . or in *any* of the other HQ offices . . . the leading contender, Dannals, is said to be making a 50-state campaign tour (*he* said he was making the tour during his recent talks at Peoria and Louisville). As far as anyone seems to know, this campaign tour is being paid for by the ARRL.

Since there is nothing that you can do now anyway, why worry about all this silly political stuff? The directors who will make your decisions for you are all in place and the old-timers still have everything under control, so it's probably best to forget about the whole thing. After all, as many amateurs say, if we lose amateur radio we can always take up photography.

CLUB 'EM

One of the major problems with ham clubs is that so few hams know how to run them. Furthermore, the whole thing is often a self-defeating system. You see, if there is a turnover of the people running the club . . . as there should be to keep a club healthy . . . the newcomers usually will not be able to benefit from the experience of the chaps who ran it earlier. The re-

Well . . . I Can Dream, Can't I? by Bandel Linn K4PP

"Your kid sounds so good, I've decided to cast him in my next picture! He'll get $10,000 a week!"

Reader Service for facing page ✓15→

suit is that the same mistakes are made over and over.

If the club is in the clutches of an old-timer clique, as many are, this is a bad situation, too. Oldtimers really don't want newcomers In the club and they tend to make the club boring and a put-off for youngsters.

Many years ago I ran a series of articles on how to run a ham club. It was so popular that we put it out as a book. Well, that was quite a few years ago and it is time for some new ideas. I'd like to see some articles by those of you who have made ham clubs work...telling the rest of us how you did it.

The main strength of amateur radio lies in the clubs, so we all have a vested interest in keeping our clubs alive and well.

You know, I wrote several months ago, asking...no, daring...clubs to send in pictures of their groups for publication. Nothing yet. When you get together for Field Day, an outing, a hamfest, an auction...any group activity...take a few minutes and get everyone together for a photograph and send it in. I'd even like to see some interesting ones (in color) on the cover.

Getting back to the clubs... and the rotation of officers. I would suggest that you elect a president for one year only... and at the same time elect a vice president whom you want to be the president next year. Keep the ex-president on the board of directors so you will have continuity. This will help the president pass the word along as to what does and does not work... why the club did such and such two years ago, and so on.

One word of guidance... remember that the club meeting is show business, not club business. Keep as much of the club business in the board of directors as you can and this will make the general meetings a lot more fun.

Be sure you have a welcoming committee which will keep an eye out for any newcomers to your meetings. Make it a point to get acquainted and keep them busy talking about themselves for the first two or three meetings. You won't be able to chase them away with a stick.

Arrange for any members with special interests to communicate their interest to the rest of the group. You may have a red hot DXer who would love to tell about the rare ones he caught recently...and will bring in the new cards he's gotten. He can also get other members interested in DX and tell them how to go about it.

You'll find chaps interested in SSTV, RTTY, computers, moonbounce, aurora communications, high-speed CW, and so on. Give them their chance to show and tell. I've already mentioned giving the home builders more than their share of the spotlight. Look for any special interest...contests, certificates, traffic handling, whatever...and get 'em up to talk and show.

New gear is of interest, too. Perhaps someone has gotten one of the new Drake keyboards...well, bring it in and show it. That's a complex piece of gear and few hams really understand what it does. We all want to see the newest gear. I always used to lug the newest stuff and I had a tough time getting it back at the end of the meeting.

If you are saddled with a bunch of hoary old-timers who sit by themselves at the back of the meeting room, figure out how to get them up front where they can get in on what is happening. The more you can get fellows together, the more they will enjoy the meeting. I really hate it when I see a club meeting where fellows sit about four seats apart, with a few up front and most toward the rear. This means they are not really into what is going on and are staying away as much as they can from the meeting and each other. Bad news. A speaker will really be put off by this. If you have a guest speaker, do not under any circumstances permit this kind of treatment. He came to speak to a group, not a room full of individuals.

Guest speakers? Easy, usually. Find anyone who is in the industry as a manufacturer or dealer and ask him in to talk.

Club events pull things together. How long has it been since the club set up a demonstration station in a shopping mall? If you do, remember you are selling amateur radio, not just putting things out for people to be confused. Make good graphic signs which explain what is going on. Try to make up some literature which will bridge

Egad! A Nine-Tube Linear

—results from the W7CSD test bed

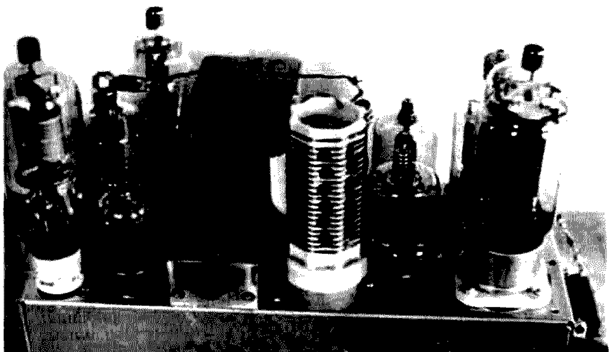
The photo bears out the title. But, no, I don't run all nine tubes in the amplifier at the same time. The photo represents the chassis used to test each of the tubes individually. I mounted all the sockets, wired the filaments and screen grids, but the plate and control grids were moved from tube to tube during the process of experimenting. In the case of grounded-grid, filament wiring also was altered.

What's the purpose of all of this?

There are a lot of reasons for buying an FT-7 or a TS-120V or an Argonaut. They are great for camping or for use where you have to use a battery. But at times you would like to have a little more power. Obviously, you could buy the TS-120S or the FL-110 linear or maybe build a solid-state linear yourself, complete with low-pass filters. But I have an apple box full of tubes. So, I decided to find out what kind of a tube linear would do the best job.

There are some problems.

Photo by Lois Kiger



The amplifier test chassis! Only one tube is used at a time.

Grounded-Cathode

First of all, you can scan the tube data in one of the older ARRL *Handbooks* and find that, seemingly, it is possible to build a kW amplifier that requires very few Watts of drive in the grounded-cathode configuration. You might have to neutralize the amplifier, but that is not a major concern. OK, so you build up this mighty fine structure and you try to get from the solid-state broadbanded driver to the grid circuit of your amplifier. If you just link couple, you will find that the impedance match is so bad that nothing comes out of your exciter. You can put 50 Ohms across the link (or in series with the link) and this will make the exciter much happier. You may get a little more out of the amplifier than the 10 Watts from the exciter but not much. I gave it up as a bad idea.

Possibly, you could design some impedance-matching network between a 50-Ohm generator and the grid in a class AB vacuum tube. But there ought to be an easier way.

Grounded-Grid Circuit

Another route seems to be the grounded-grid circuit. As will be seen, this has possibilities with some refinements, but it is very doubtful that with 10 Watts drive you can go to more than a few hundred Watts

input with a single stage. You easily could go to a kW with a two-stage linear. Actually, the commercial solid-state amplifiers are not getting a power gain much in excess of 10, either. Here, again, with grounded-grid, the input impedance varies from tube to tube and may be a country mile from 50 Ohms.

In the past, many companies have built grounded-grid linears with an untuned input. Hallicrafters, Loudenboomer, and DenTron more recently have done this, just to name a few. It worked very well if you had a 100-Watt tube-type driver. With the advent of 100-Watt broadband solid-state rigs, it doesn't work well at all. This is doubly true if you have a 10-Watt solid-state rig. So, DenTron and possibly others are installing tuned input circuits in their linears and marketing tuned input kits to be installed in existing amplifiers.

If you are going to build your own, two less-than-desirable conditions exist. First of all, you will have to wind a big bifilar-wound ferrite filament choke unless you use an indirectly-heated cathode tube like the 7094. Second, if you are going to get the maximum out, you will have to build a band-changing input tuner or half a dozen switchable, fixed tuned inputs for that many bands.

Tube	Plate Volts Ep	No Signal Plate Current Io mA	Plate Current w/excitation Ip	Grid Volts Eg	PA/P7*
6146	460	No	No		Less than 2:1
829B		Good	Good		(G3 tied to K internally)
6LQ6	900	5	200	−10	9:1
7094	1500	40	160	0	12:1
813	1500	10	60	0	2:1
4-125A	1500	5	35	0	1:1
4-400A	1500	20	86	0	6:1
3-400Z	1500	50	160	0	12:1
811	1500	35	65	0	1:1

Table 1. Grounded-grid amplifier test results. All grids tied together; untuned *input. *Power output of amplifier compared to power output of FT-7.*

EXPERIMENTAL RESULTS

Grounded Grid Circuit

Table 1 shows the results of driving seven different tubes with an FT-7, as shown in Fig. 1. The 6146 and the 829B tubes have the suppressor grid internally connected to the cathode and just don't function very well in grounded-grid. However, note the gain of the 6LQ6. If all you are looking for is 100 Watts out, this may be the answer. Most any TV transformer and bridge circuit will give you the makings of a power supply. The circuit is simple and does not require filament chokes. The 7094 is a dandy, but expensive. So is the 3-400Z and would be even better with 3000 volts. At a glance you could conclude the 813, 4-125, and 811 are flat tubes. Not so. They just mismatch 50 Ohms too far. The 4-400A is not so far off and also might look better with 3000 volts.

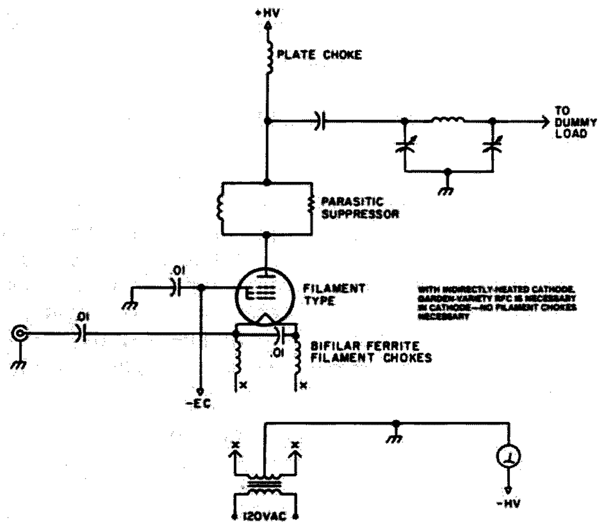


Fig. 1. Grounded-grid amplifier test circuit.

Table 2 shows data for the same amplifier with a home-brew antenna tuning unit between the FT-7 and the amplifier (Fig. 2). This unit was adjusted to give a 1:1 swr presented to the FT-7. Note that the power gain has skyrocketed in all cases. The 7094 gain has gone to 18:1! The 3-400Z might be nearly this high using 3000 volts. If you have an 811 in the junk box, it now looks like a winner at 12:1. Again, you might go this route with the 6LQ6. But you *do* have some kind of an input tuned circuit to add. It adds hardware, takes up space, and is another circuit that needs to be manually adjusted.

Tube	Ep	Io	Ip	Eg	PA/P7
6LQ6	900	5	210	−10	12:1
7094	1500	40	190	0	18:1
813	1500	10	155	0	14:1
4-125A	1500	5	80	0	10:1
4-400A	1500	20	135	0	12:1
3-400Z	1500	50	165	0	14:1
811	1500	35	125	0	12:1

Table 2. Grounded-grid amplifier test results. All grids tied together; tuned *input.*

Passive-Grid Circuit

A third possible approach is the "passive-grid" circuit. I built a big one of these several years ago, driven with an FT-101.[1] The 1979 ARRL *Handbook* has such a circuit, as does one of the older Bill Orr *Handbooks*. The ARRL used an 833, whereas the other one used some kind of a big tetrode. If you have a 100-Watt tube or solid-state exciter, it's a good circuit. With 10 Watts, and using a positive screen voltage, it may be attractive to some. The input impedance is 50 Ohms, almost all resis-

1. *CQ*, April, 1976, p. 31.

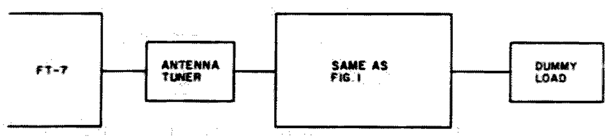

Fig. 2. Block diagram of test circuit of Fig. 1 using tuned input circuit (antenna tuner).

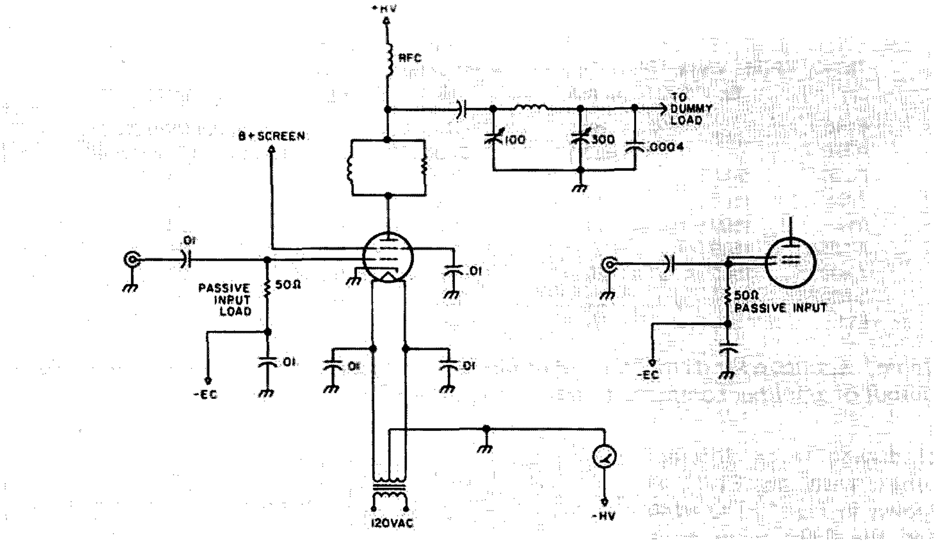

Fig. 3. Passive-grid amplifier test circuit. Screen grid is held positive.

tance. I used seven 390-Ohm 2-Watt resistors in parallel. This makes the FT-7 or other solid-state 10-Watt exciter very happy. Unfortunately, it also limits the amount of voltage that can be applied to the grid. The one disadvantage is the necessity of a screen supply. In the test case, the screen and control grid voltages were adjusted for optimum output. Control-grid voltage was supplied from batteries.

Table 3 shows the results of driving the passive-grid circuit (Fig. 3) and also applying optimum positive potential to the screen. The results compare fairly well with the grounded-grid untuned input. The 701A, which is not a common tube, is tops and the 7094 and 4-400 look fairly good. Again, the 4-400 would look better with higher voltage. The simplicity of the circuit has something going for it.

Table 4 is same circuit, except that it has all grids tied together, if there are more than one. This is singularly unimpressive although the 3-400Z still might look very good at higher voltage. Both of the passive-grid circuits might look much better if you had a 100-Watt driver and, of course, a 100-Watt non-inductive 50-Ohm passive-grid resistor.

OK, fellas, study the data and draw your own conclusions.

Having been a teacher for most of my life, I know this is not the way to end. I see some strange expressions on your faces. You, in the front row, what's your problem?

How did I do the experiment and how valid is the data?

The FT-7 was connected through an antenna changeover relay through the amplifier under test and through an swr meter (which was also calibrated for relative power) to a Heath Cantenna®. With the antenna relay not energized, the FT-7 was fed through to the load and the relative power was set to 10%. Then the antenna relay was energized and the amplifier fed to the load. If the meter reads 60%, we have a power ratio of 6:1. On the high output ones, I set the power meter at 100% with the amplifier on and then compared to the FT-7. If it reads 8%, then we have a power ratio of about 12:1.

In each case, the amplifier voltages and loading were adjusted for maximum power out without getting the plate too red. The actual power ratios may be a little in error, but the differences are so great that the conclusions are evident. An rf ammeter might be used if you choose to use one. Since I^2R equals power, $(I_{amp}/I_{FT\text{-}7})^2$ will give you the power ratio.

What was the frequency of the tests?

I originally planned on 80 meters, but the tank circuit wouldn't reach that far, so I used 40 meters.

How about the long grid and plate leads going to some of the remote sockets on the chassis?

Not good at all. But you can get away with it on 40 meters. Nothing even threatened to take off and oscillate. But you better get those leads much shorter if you expect to work on ten.

What will this thing do on a real live antenna rather than a dummy load?

It will do just as well and very likely better. If you have a good antenna with a swr of 1:1, it will behave just like the dummy. If you have an antenna with an swr of 2:1, the FT-7 output to the antenna will be considerably reduced, but the pi-network in the linear will overcome this and will have full output. Instead of a power ratio of 10:1, it might very well go to 12:1 or more.

What's the big difference between an amplifier for a 100-Watt exciter and a 10-Watt exciter?

Another very good question and one that a lot of you may not have thought about. If you have a 10-Watt exciter, you want to get all the power gain you can get. If you get a gain of 20, you still only have 200 Watts out. If you have a 100-Watt exciter, an amplifier with a gain of 6 is pretty good. You now have 600 Watts out and very near the legal limit of 1000 Watts in. A low-mu grounded-grid triode might be ideal. On the other hand, a

Tube	Ep	Io	Ip	Eg	E_{screen}	PA/P7

Table 4. Passive-grid test circuit results after tying all grids together.

3-400Z (or 500Z) or a 4-400A in a passive-grid circuit would be quite adequate.

Which one did I decide to use?

Well, I built two. Both of them were chosen because I had the tubes. One was the grounded-grid, untuned input 7094 which I succeeded in getting inside a medium-sized cabinet complete with power supply. I can stick the outboard antenna (input) tuner in if I want to. The other uses the old Western Electric 701A in the passive-grid circuit with 70 volts on the screen. I had three of them and two sockets. (If anyone wants a 701A and a socket, make me an offer.) In any case, the decision rests on personal choice, what's in the junk box, and what you would settle for in the way of output.

A Bit of Confession

You would be surprised at the number of Master's and Doctoral dissertations that have been founded on a preconceived conclusion with a bunch of warped data to prove what the author already thought was so. Well, I had a preconceived conclusion that the passive-grid circuit was just great and everybody should build one. Before starting on this little data collecting venture, I had already built the 701A. Since it worked so well, it must follow that all passive-grid circuits are fantastic. As you can see, my data disproves this hypothesis. On the other hand, it turns out that I have built a good case for the tuned-input grounded-grid for just about any tube you want to choose. I never did try the 701A, grounded-grid, but I suspect that it would be excellent. By the same token, a 4CX1500A might be good in a passive-grid, but I don't have one.

If you have a strange unknown bottle in your junk collection, cobble up a junker linear and see what it will do. Then build a finished model using whatever circuit works the best.

Have fun! ■

THE RTTY ANSWER

Scott Nelson W7KUF
Box 56, Snowbird Village
Snowbird UT 84092

Drama on Mt. McKinley

—ice, snow, and amateur radio

At 13,000 feet and approaching Windy Corner.

It has been many years since the mountains started influencing my life. As a youngster living in New Hampshire, I remember reading books and looking at photos of far-away peaks bearing no resemblance to the rolling hills of New England. It took years, but in the early seventies I moved to Utah and took up residence in the Wasatch Mountains at Snowbird, one of the country's premier ski areas.

Now, snow-wise and educated in ice and avalanche perils, I sometimes long for the White Mountains of New Hampshire, realizing that a mountain doesn't necessarily have to be over twelve thousand feet and snowcapped to impress me. It was in camp at 14,400' on Mount McKinley, at −25°, when this thought first came to me. We had been climbing for six days before reaching this camp, and now we were into our third day sitting out an endless storm that buffeted our sturdy dome tents on this high ice field, not far from the arctic circle. Above us, Denali, as the mountain was known to the Indians, rose to over twenty thousand feet of ice, granite, and snow.

This was an expedition that had been six months in the planning and had drawn from climbers and skiers associated with Snowbird. Dick Bass, the Texas oilman and owner of the 'Bird, was there with his two sons and two daughters. Bob Bonar, Director of the Ski Patrol, and Liam Fitzgerald, Director of Avalanche Control, were both there, as well as Dr. Gernot Spalleck from the Medical Clinic. The expedition leader was Marty Hoey, Director of the Safety Patrol and an extremely capable climber. Among other notable credentials, she is a member of the China/Everest expedition for 1982.

It was early December, 1980, that plans began to materialize. We each embarked on a conditioning program that included weight lifting and running or bicycling in addition to our normal skiing. New equipment had to be purchased and tested—with safety of prime concern. It was the safety factor that first led me to consider taking ham radio along.

A quick check of the repeater directory confirmed the availability of two meters within range of the mountain. In mid-winter tests in the Wasatch Mountains, both my own Yaesu FT-207R and a friend's Kenwood TR-2400 proved unacceptable because of the whistles and bells, memories, displays, weight, and nicad drain. Quickly, it became apparent that the criteria for acceptance were small size and weight, simple operation, and synthesized frequency control. Both the Tempo S-1 and Icom IC-2AT fit the bill and tested out well. Through the assistance of the folks at Icom, I was soon outfitted with a new hand-held equipped with an alkaline battery pack, and I was ready to go.

The rubber ducky was discarded in favor of a quarter wave, but tests soon showed that it, too, would be marginal. One hike into the mountains with VoCom's five-eighths-wave whip convinced me that there was no other way to go, although at one time I did consider a collapsible three-element beam. Like other complicated solutions, it was discarded in favor of the simple whip. It was to provide the margin of safety we required.

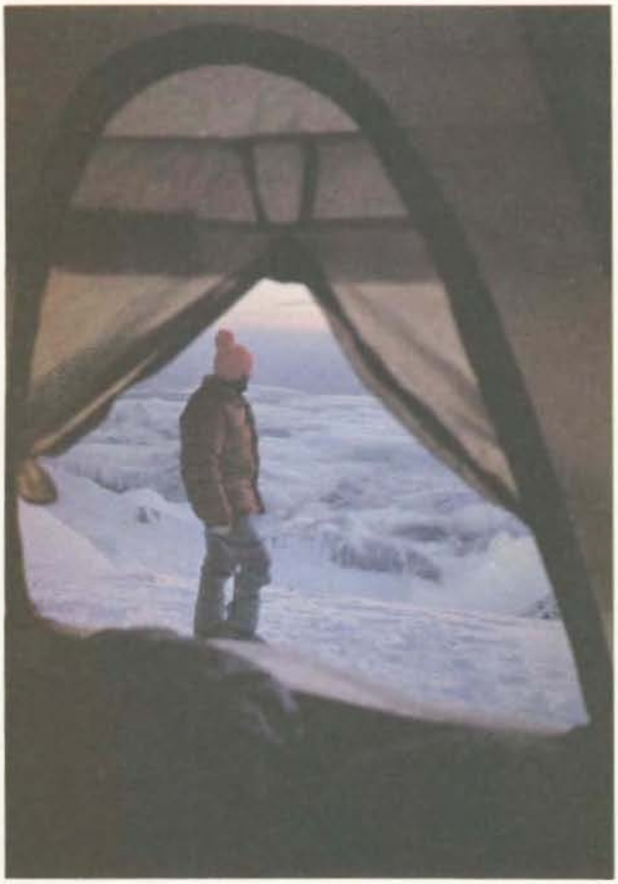
Next on the planning agenda was the Anchorage link station since I wanted to operate on 2 to 20 meters crossband and maintain contact with my family and ham friends in Salt Lake City. Several calls on 14.292 MHz soon brought Ray Morris KL7C into the picture. Being quite familiar with the Wasatch Front, he soon was impressed enough with the expedition to volunteer his services as our much needed link.

Scott Nelson transmitting at 14,400 feet during the storm. (Photo by Bob Bonar)

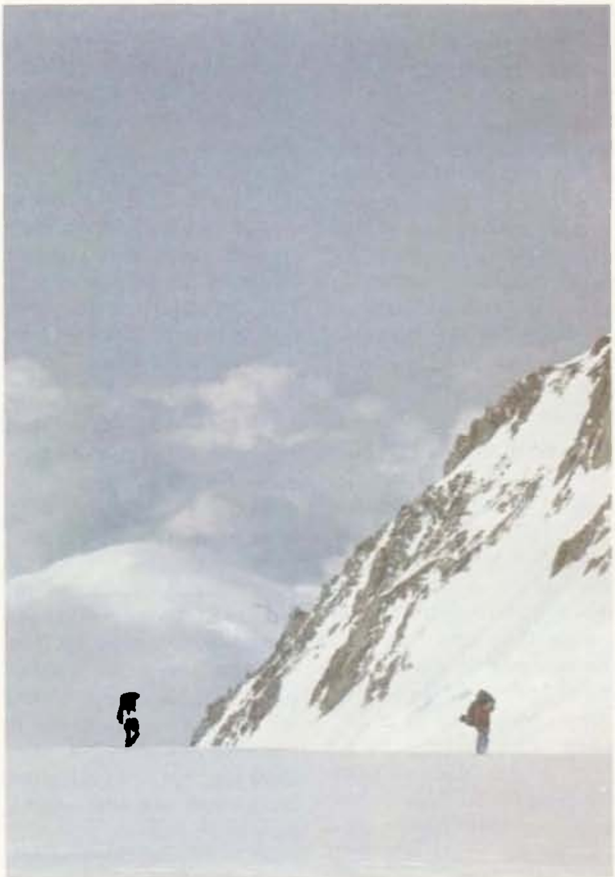
Ray, in turn, contacted Roy Davies KL7CUK in Montana Creek, about seventy-five miles from the mountain, who agreed to back us up with simplex coverage. Ray devised a direct-coupled patch while Roy relied on acoustic coupling (as simple as holding the mike to the speaker!). Russ Knodel KL7HC also came aboard as backup, and we were set!

After a shakedown climb on Mt. Rainier (following the same route where eleven climbers tragically lost their lives a month later), we were off to Anchorage, where, in addition to our sixty-pound packs, we divided over six hundred pounds of group gear that would be towed on sleds behind us. We would be using specially-equipped mountaineering skis on the lower glaciers, thereby eliminating the need to shuttle loads. All one hundred twenty pounds apiece would be carried in one trip until we reached the steeper sections where skis would be traded in for crampons.

The Anchorage-to-Talkeetna leg was on the Alaskan Railroad, a three-hour trip that occasionally yielded a glimpse of the distant mountain. Nearing Talkeetna, we could see ski-equipped planes heading north toward the glaciers where climbers would be dropped off.



Dr. Gernot Spalleck at 16,000 feet, at 2300 hours.



Climbers at 14,500 feet.

Soon it was our turn, and as we stuffed ourselves into the Cessna 185 among packs, sleds, and skis, the drama began. Our pilot, Cliff Hudson, climbed to 8000, and thirty minutes later entered One Shot Pass (no turning back!) and descended to the Northeast Fork of the Kahiltna Glacier (Kahiltna International, to the pilots) where we established base camp at 7000 feet. Here we were in the shadows of fourteen-thousand-foot Mt. Hunter and seventeen-thousand-foot Mt. Foraker. Several other expeditions were preparing to leave, so we decided on an overnight stay before setting out on our own the next morning, after organizing loads for the final time.

I was surprised to find that I could access the 90/30 machine in Anchorage from a spot near the airstrip. A check with KL7CUK confirmed our arrival, and a schedule was made for a week later when we expected to arrive at 14,400. Although I would try to access the repeater daily, I did not expect to be able to do so until clearing the shadow of the mountain and arriving at 14,400.

The climb from 7000 to 11,000 was a joy. We encountered only one snowstorm, and on several days climbed in shorts with no shirt. The sun was unbearable during the day, and at night the mercury often plummeted fifty or sixty degrees! We climbed anywhere from one thousand to fifteen hundred feet per day depending on the steepness, though generally it was moderate low-angle glacial terrain over a few steeper ice falls. Crevasses were mostly bridged with the winter's snowfall, though occasionally a gaping hole would open up beside the trail.

We roped together from the moment we left the airstrip, a move I was most thankful for on the day I suddenly plunged into a hidden crevasse. Luckily, the rope prevailed, and I didn't sink below the surface. We often joked about our turtle routine, something that occurs as you are trying to right yourself or get up after falling with the heavy pack strapped to your back. Sounds funny, but try it sometime!

After 11,000, the climb got more serious, for facing us was a pitch called "Motorcycle Hill." The sleds were cached with our skis at the base and we began one of several shuttle climbs with loads. The next camp was established at 12,500 just below a pass called "Windy Corner." We were anxious to reach 14,400, for there we plannned a few rest days before heading higher. Two loads to 12,500 in one day, and we were off the next day for 14,400. Windy Corner was anything but windy, but medium-angle blue ice proved to be a tricky traverse. With crampons and ice axes, however, we passed with no problems.

In camp that night a day early, I once again tried the repeater and got through. Ray and Roy were standing by as they had all week in case I managed to get into another hot spot. No one was on twenty meters from Salt Lake that evening, so, after a wrap-up of the week's activities, we signed off till the next evening when we would try to run some patches to Utah.

Returning to 12,500 feet the next morning, we loaded the balance of our supplies on our backs and were

off again around Windy Corner, which was still windless. At 1800, I was again able to get into the 90/30 repeater, and for the first time there were Al Wolff KC7O and Mike Mladevosky WA7ARK in Salt Lake City patched through from twenty meters. A few minutes later, Mike had my wife Suzi on the phone, and from twenty-five hundred miles away via two and twenty, I was able to report our progress.

The looks on the faces of the other climbers were of amazement as they heard me talking with Suzi and my son Tyler on what looked to them to be a simple walkie-talkie. Their only experience with radios till then had been with the sometimes-less-than-efficient Motorolas used by the ski patrol.

Following that first conversation, I had daily requests for message-handling from other members of our party, usually consisting of one-way phone calls from Anchorage. The pattern remained the same: the 1800 check-in on 90/30, with WA7ARK and KC7O standing by on twenty meters for either KL7C or KL7CUK.

I tried to limit the on time to fifteen minutes to conserve batteries, but by the time we got through with check-ins, messages, and weather reports, it usually ran more than thirty minutes. I came equipped with four sets of alkalines (24 AA batteries), but the cold weather was eating them up faster than I planned. The procedure was to take the unit out of my pack at 1700 and place it inside my down jacket for warmth. Some evenings this wouldn't be possible, or perhaps was possible for only ten or fifteen minutes. Mike always remarked on those evenings about the deterioration of my signal in both strength and quality. "Forgot to warm up tonight, didn't you, Scott?" became his standard greeting.

We ran both simplex and repeater patches with equally great results. Al taped all transmissions on cassette, and eventually they will be part of an audio/visual show I am planning on the climb. Suzi found it easier to hop into the car with Tyler and drive to either Mike's or Al's QTH than to rely on a phone patch across town. Undoubtedly, Tyler (2½ years old) enjoyed the excitement of adventure much more while sitting at (or on) Al's or Mike's bench.

If you have never spent three days in your sleeping bag waiting for the weather to clear, you haven't missed much. The evening radio call was the highlight of the day—except when the wind was whipping snow past you at forty miles per hour at −25° F. Five days after arriving at 14,400, it finally cleared and we prepared to climb to 16,000 feet. The previous day it had stopped snowing long enough for us to make a carry to 15,000, but now we were prepared to go up the most difficult section of the mountain.

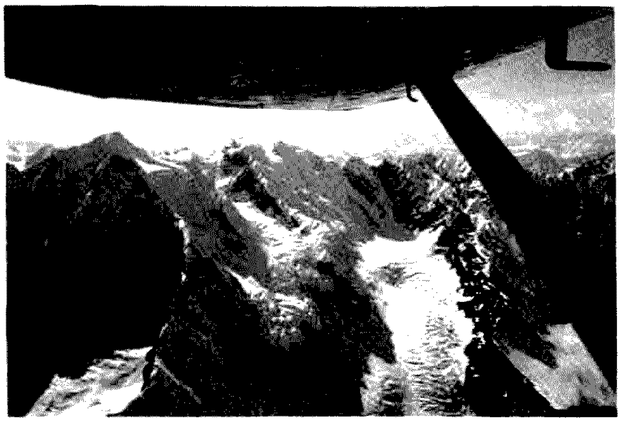
Suddenly, two French climbers came into camp asking if we had a doctor. A German climber camped near them had come down with pulmonary edema and urgently needed attention. After considerable discussion, Dr Spalleck predicted that the climber would be in a life-threatening condition if not treated immediately with the proper drugs and, most importantly, taken to a lower altitude.

At 1000 I put out a call again on 90/30, which also is the RACES repeater in Anchorage. Moments later, Roy KL7CUK was on frequency and mobile on his way to Talkeetna where there was both an FAA Flight Service Station and a Park Service Field Station. Arrangements were made for a Bell 206 to leave Anchorage, 150 miles away, refuel in Talkeetna, pick up a Ranger, and head on to McKinley where the morning's clear skies were rapidly deteriorating. The ceiling was still below us at 11,000 feet, but clouds now were forming in the high basin where we waited with the now-critical climber.

Dinner in a blizzard.

After probing the area for crevasses, a landing area was stomped out and flagged in the new snow. By now we were totally clouded in, and from Roy I learned that the rescue helicopter was approaching the mountain. Four hours had gone by since the first call went out, and now the

Rescue helicopter taking off.



Just past One Shot Pass.

The expedition's banner.

German's life depended on the helicopter getting in.

At the same time we first heard the chopper approaching, we also noticed a bit of blue sky, however, and by the time he arrived, the sky had opened enough for him to land on his first approach. While the downwash from the blades created a white-out with the new snow, the pilot never backed off on the pitch and hovered with the skids just touching the snow as several volunteers loaded the climber into the bird. He was off as quickly as he had arrived, with the clouds closing in as he disappeared from view.

What had begun as a novel experiment in backcountry communications had suddenly proved to be an invaluable contribution to saving a man's life. We returned to our camp and again made preparations to join the rest of our group, now more than two-thirds of the way to 16,000 feet.

Because of uncertain weather we dared not wait another day, so at 1600 we broke camp and started up the steepest section of the mountain. I hoped that the cold I had caught a few days before wouldn't affect my climbing, but by 15,000 feet, my breathing told me it had. At 2030 that evening, we dragged into camp to join the others, my lungs strained to the limit. I had told Roy earlier that I probably would miss that evening's call and had asked him to relay that information to Utah.

The next morning, my high-altitude headache persisted and a new storm was raging. Staying on an exposed ridge at 16,000, we decided to push on to 17,500 where we would be more sheltered from the storm. This was a relatively easy climb, but also the most beautiful in clear weather. Disappointed to miss the photo possibilities, we pushed on through the snow to high camp where my headache still bothered me.

That evening's call was next to impossible, for I had to climb an exposed ridge in order to hit the repeater, and in doing so opened myself up to the full fury of the storm. (Listening now to KC7O's tapes of that and the next evening's conversations, I can understand the alarm felt by those not on the mountain. My voice lacked clarity and enthusiasm, for the altitude was affecting me more than I realized. I remember hearing my little boy's voice and feeling very sad I was not with him and his mother.)

The next morning, the storm continued and we spent the day in our sleeping bags drinking soup and tea and playing cards. Still I felt no better, and by the second morning knew I would have to go back to 14,400 to re-acclimate myself if I wanted to reach the summit. I left at noon with several other climbers, and we reached our lower camp by late afternoon, where my headache immediately disappeared. I would have to spend at least twenty-four hours there before going back up, but the next morning we awoke to blue skies and knew that the others would be going for the summit. Not having the logistical support for two summit attempts, we all departed for base camp, knowing that the others would join us in a few days.

Disappointed, yes, but, as you quickly learn as a climber, summits are not everything. The climb to 17,500 feet had been the most exhilarating experience of my life and I could not regret a moment of it.

We arrived at base camp at 1945 that evening. With twenty-one hours of daylight and three hours of dusk every midsummer day, Alaskan pilots can fly nearly anytime the weather permits. Within an hour of the time our party was ready, Cliff Hudson was again landing his plane on the strip and we were hurriedly loading our gear and ourselves into his plane. With the weather closing in fast, Cliff elected to take us all out in one load and come back for the remainder of our gear when the weather cleared.

All the passes were socked in, and our only way out was to follow the Kahiltna for twenty or thirty miles to the toe of the glacier. After nearly three weeks, we saw green again, and a short while later were landing in Talkeetna. Cliff's son met us at the dirt strip with his pickup truck and, as we piled out of the plane, handed us each a cold beer. Sitting on the tailgate still in our climbing boots, gore-tex, and wool clothes and feeling slightly over-dressed for this warm summer evening, our conversation drifted to our next adventure. What would it be . . . South America next summer, or maybe Nepal and the Himalaya? I'd have to check the repeater directory on those two. Meanwhile, having finished our beers, we headed into town for a typical American meal: hamburgers and french fries. After three weeks of instant mashed potato mush and eggs, it tasted like a steak dinner.

Cliff was sitting there with us, a cigarette hanging out of the corner of his mouth. Taking a deep breath he said, "There now, how do you like breathing some of this heavy air for a change?"

Heavy air, indeed! ■

The Simplex Autopatch

—a telephone interface for everyone's two-meter rig!

Several local hams have been talking about a different kind of VHF autopatch that uses one frequency. This discussion has been going on from time to time over the past few years. We have designed many paper models of such a machine, with nothing more than a few beers as inspiration. But, in the August, 1978, issue of *73 Magazine*, there was a report of a machine built by John Walker WA6MHF in southern California. Well, needless to say, this sparked the discussion again, which this time actually led to construction.

For those of you who don't know what a single-frequency autopatch machine is or how one basically works, read on. Since most readers know what a traditional autopatch repeater is, let's start by explaining that it uses two frequencies (an input and an output), a duplexer (or similar device), and some control circuitry. Once the autopatch repeater is accessed, the transmitter is always transmitting and the receiver is always listening. Thus, two frequencies are used at all times.

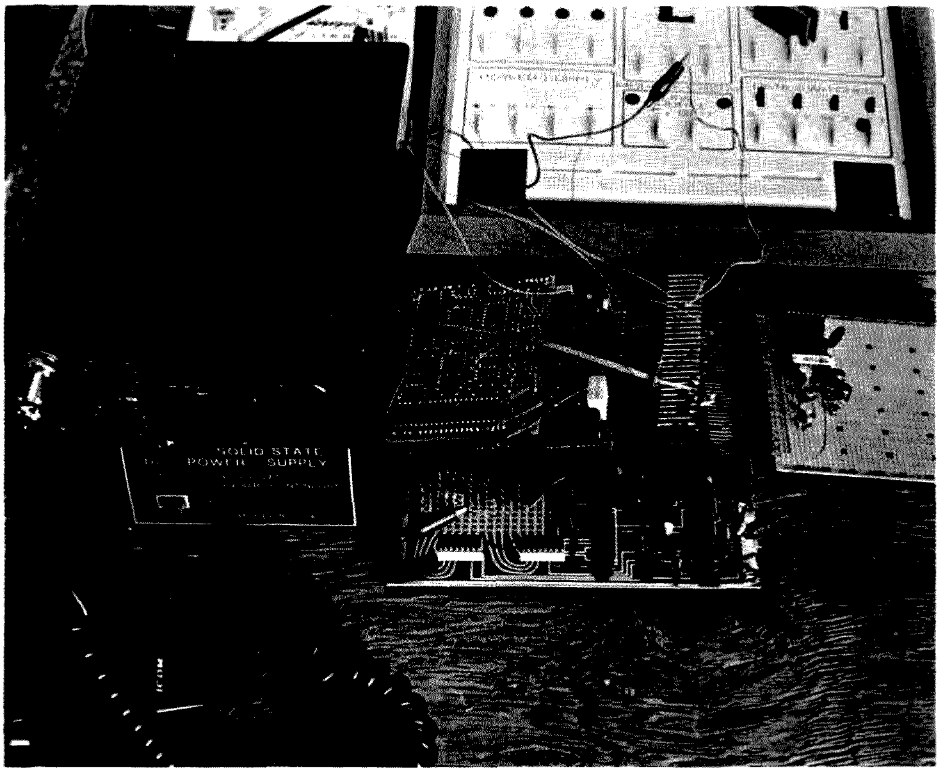

Fig. 1. Complete hardware for simplex autopatch.

Using this method generally requires a duplexer to provide rf isolation between the repeater's transmitter and receiver circuits, in order to use one antenna.

The control circuitry provides the means to access the phone line, limits the length of the call, and terminates the patch.

The simplex method uses a single frequency, does not need a duplexer (unless you are in a *very* high rf environment), and requires slightly different control circuitry. The receiver is always listening on the simplex channel. When a signal is received and the appropriate tone command is received from the user, both the ON DIGIT and COR LINE enable a circuit to connect

the phone line to the receiver and transmitter. At the same time, the transmitter is keyed on for 1.3 seconds and then off (in the receive mode) for about 40 milliseconds. What the user hears is dial tone from the phone line that is interrupted by "clicks" or the receive window. The user then keys his transmitter, and in less than 1.3 seconds (the time until the next receive window), the patch receiver will detect his signal (COR LINE) and inhibit the transmitter. The patch receiver is now locked in, listening to the user. The user then transmits his touchtone™ signals through the patch receiver to the phone line and on to the central office.

Local patch-control circuitry should check for local calling only and the length of the patch and dump the call if calling criteria are not met. Since this is not the purpose of this article, I will not go any further. When the user releases his transmitter button, the patch receiver responds by enabling the patch transmitter again in the same way as described previously. Thus the user can hear his call being processed (the called party's phone ringing and being answered). The user may talk to his party in a normal push-to-talk mode with the exception of the 1.3-second maximum delay and the "clicking."

Disconnecting the patch is simply a matter of the user keying his transmitter, pausing for the receive window, and signaling the disconnect code. The OFF DIGIT code also disables the patch transmitter from keying and locks the patch receiver in the receive mode.

The disadvantages to this method of autopatching are the "clicks" and the delay in speaking to your called party. The "clicks" are somewhat distracting to some and are quite tolerable by others. I found that with increasing use you can get used to the "clicking," and after experimentation, about 1.3 seconds was about the right speed to sample for a user's signal. Of course, you can set the speed to just about anything you feel is right, within reason. For example, trying to make the "click" shorter by narrowing the receive window less than 40 milliseconds depends on your transmitter-receiver switching time. Obviously, you should use a crystal-controlled receiver (synthesized receivers are much too slow, about 140 milliseconds). Also, the same applies for the transmitter as well. Another point is the method used to switch the antenna from receiver to transmitter. Relays are also much too slow because they add to the total switching transition. Rf detecting (diode switching) in the newer VHF radios works very well.

The advantages are cost, simplicity, portability, and frequency conservation. Since there are no duplexers or similar rf plumbing, you save about $350 to $400. You don't need an expensive VHF radio such as a Motorola Micor (which a good repeater would use and costs over $1000). I used an Icom IC-22A, which was purchased used for less than $200. The modifications amounted to tapping the audio, the COR line, and the transmitter key. Later, I removed a 22-microfarad capacitor from the squelch dc amplifier to speed up the switching time. There are other modifications that could be made to improve the switching time, but I decided to study the present design before making any more changes. Since the VHF radio is small and can be run from a battery and there is no rf plumbing, the machine is very portable and has good emergency communications potential.

All you need is a phone line, a quarter-wave whip antenna, and a single channel assignment.

The photograph shows the second breadboard version of the machine. The first version was a real rat's nest. Come to think of it, the second version has just as many wires going in every direction, but it works quite well. Ken Koster WA7RYP is one of the locals who worked on this project with me. Ken was eager to supply some vital circuits as well as his experience to make this machine work. Ken loaned me his Teltone™ M-907 touchtone decoder from his 450-MHz repeater. The decoder is about 4 inches long and 3 inches wide. It uses opera-

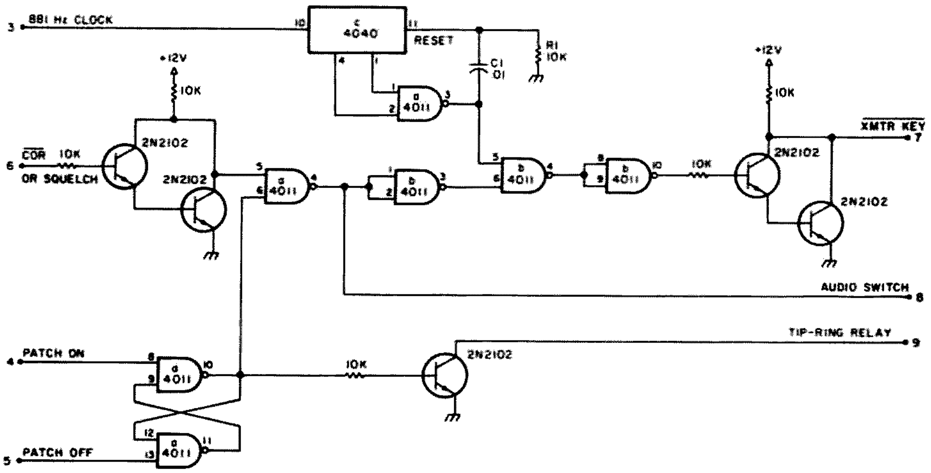

Fig. 2. Interface logic circuit.

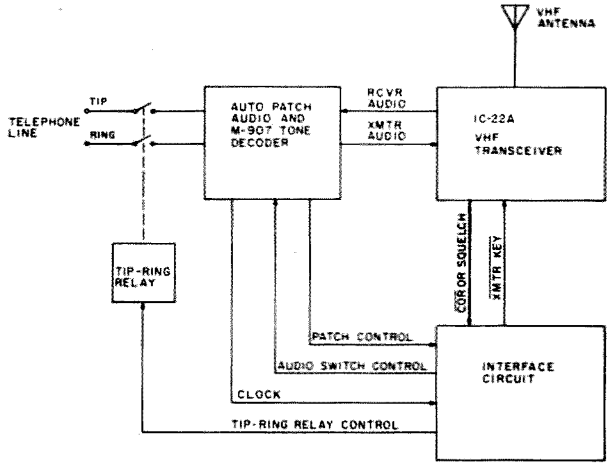

Fig. 3. Block diagram.

tional amplifiers for tone conditioning and a 40-pin LSI for tone verification, timing, digit output, and other functions. The decoder has an 881-Hz clock output which we used as a timebase to the control circuit for switching the transmitter and receiver. The unit costs about $85 and it mounts on another one of Ken's boards piggy-back style. Ken's main board also contains the autopatch audio and telephone interface circuitry. This circuitry is shown in the photograph in front of the Heathkit Digital Designer which contains the interface and control logic for the IC-22A.

After a few hours of blitz building, we had the second version ready for on-the-air tests. Using a Wilson Mark IV with a tone pad, Ken punched up the access, got the dial tone, punched up the local number, and there she was . . . the good ol' time lady. We dialed up a few ham friends for reports and made a few adjustments to the audio levels at the same time.

Later on that evening, Ken and I were talking simplex on the machine's VHF channel. I got this wild idea to call our friend Dave Miller WB5WCG in New Mexico! Ken topped it by suggesting that he dial the number from his location about 5 miles away. So I disabled the long-distance dump circuit and Ken started to dial Dave. A few seconds later, Dave was talking to Ken about our effort. A few short years ago, Dave was a local ham who was participating in our efforts for a single-frequency machine. Actually, he was surprised we finally did it. He knows that we dream a lot and that our fantasies seldom turn into connected silicon chips. During this live on-the-air conversation, Dave was giving his call and identifying the machine. The call lasted just a few short minutes, but when it was over, several hams who were listening in started calling the DX in New Mexico!

The schematic of the interface logic is shown in Fig. 2. An 881-Hz clock signal from the M-907 is used to clock a CMOS 4040 (a divide-by-4096 chip). The 4040 is configured to provide a receive window pulse every 1.3 seconds. By referring to a data book, you can easily change the sample rate and receive window pulse width. The output of the 4040 is NANDed and used to reset itself (the 4040). The value of R1 and C1 are not very critical. The 4011 latch gates the output of the COR Darlington transistor pair to allow the COR line to control the output of the 4040. The COR LINE and the 4011 latch control the transmitter keying line by using some 4011 NAND gates. A few transistors are used for the receiver COR and key line. The resistor values of these circuits are not very critical either. The transistor Darlington circuits may require some changes for the specific radio they are to interface. Fig. 3 illustrates a block diagram of the machine. The audio circuits interface the radio to the phone line and the tone decoder.

Remember, this machine is not a repeater and cannot be used to contact another ham via a downlink radio path. The machine can only transmit what it hears from the phone line and send to the phone line what the patch receiver hears. I would be interested in hearing from anyone who knows about any similar efforts or any improvements. Please, SASE letters only. ■

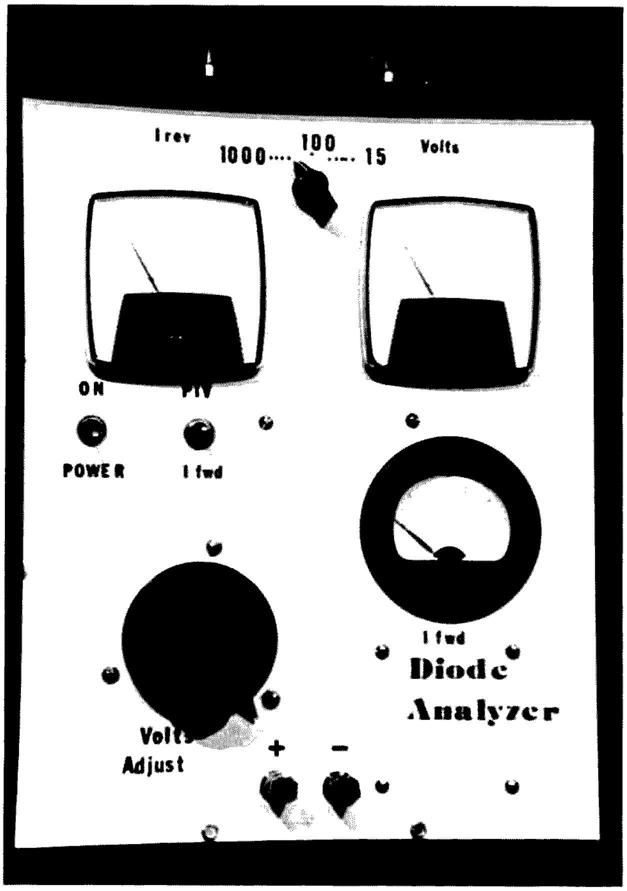
The Cheapskate
—a checker for bargain diodes

With a mighty hum and a cloud of smoke, another power supply bites the dust! Sound familiar? If it does and if you roll your own as I do, the diode analyzer discussed here will help save your projects by preventing unworthy diodes from creeping into an otherwise good job.

After a few of my bargain diodes turned out not to be bargains, even after checking them on a "diode tester," I decided to build a tester that would check the actual prv and forward voltage drop of a diode and to do it with as little cash outlay as possible.



Front panel of the diode analyzer.

The Cheapskate analyzer will provide you with the information you need when selecting or grading bargain-pack diodes. The culls can be used for noncritical applications, one-way wires, etc. And, the good ones can be graded for performance at whatever voltage or current levels are required by the circuit they are to be used in. It requires *no* external meters or connections other than to the diode under test.

Experience has taught me that test jigs and alligator clip leads with 1000 volts or so on them can be an unhappy combination if one gets careless or is in a hurry. This is the reason for the all-in-one-box design.

This device will allow you to test diodes under actual anticipated operating voltages or currents and to match diodes for HV rectifier strings or other purposes.

This article is not a step-by-step, how-to-make it type for the simple reason of economics. It does not make sense to build an expensive device to test bargain semiconductors. Although once built, I would recommend testing any diode that you intend to use, even so-called first-quality ones, as it will prevent some nasty surprises.

The tester (Fig. 1) consists of two variable-voltage supplies and their associated metering and switching circuits.

VT1 is a 0-to-130-volt Variac; a 50-Watt rheostat could be used instead. The idea is to vary the input voltage, so whichever means your scrounging or junk box provides will work.

R1, R2, and R* are limiting resistors and limit the voltage out of the prv test section to agree with the meter scale in use. In my case, this meter (M2) was a 50-μA unit with scales of 100, 15, and 3. So, I set R1, R2, and R* and R4, R5, and R6 for full-scale readings of 1000, 100, and 15 volts at maximum setting of VT1. The meter that you use in your voltmeter circuit will determine the values for these resistors. I would recommend a meter with a 50- or 100-μA movement as best suited for this application. The meters that you have available will depend on the size of your junk box or what's on sale at the local hamfest.

As high-current dc meters are not cheap—even

used—the best bet is to use a shunt. My favorite is a 0.001-Ohm shunt used with a 50-μA meter. The shunt is either 11-7/8" of #10 solid copper wire or 7-7/16" of #12 solid copper wire. The series resistor value will depend on the internal resistance of the meter and the desired range of the meter. Just divide the full-scale reading of meter in volts by the current in Amps needed for full-scale deflection. Then subtract the internal resistance of the meter used to find the series resistor value (e.g., 0.025 volts full-scale and 25 Amps. 0.025 V/0.00005 A = 500 Ohms − 300-Ohm meter resistance = 200-Ohm series resistor). For other ranges, remember that the voltage drop for the 0.001-Ohm shunt will be 0.001 volt per Amp of current through the shunt. Use #10 wire for 30 to 50 Amps.

When measuring the internal resistance of meters with sensitive movements, use a series resistor of known value to prevent exceeding the range of the meter under test.

Transformer T1 is a small unit of unknown origin that provides approximately 1000 V ac to D1 and D2, which are 1-kV, 1-Amp units. C1 and C2 are 1-μF 600-volt paper caps. A 1- or 2-μF, 2-kV oil-filled unit would be perfect here but will have to wait until the next hamfest. Do not use a string of high-capacity electrolytics here as it will strain T1 and take quite a time to discharge. M1 is a 50-μA meter from the same junked unit as M2. The meter scale here is unimportant. All that is necessary is to indicate when a few microamps of current begin to flow in order to establish checkpoints when matching diodes.

T1 can be any type of small transformer capable of delivering whatever maximum prv you wish to check. Since current drain is very small, the smaller T1 is physically, the easier it will be to package. R3 is a limiting resistor and should be high enough to limit the shorted output to around 100 μA at T1's maximum output. (Yes, Waldo, diodes do come as dead shorts occasionally and some of us can't guess which end of an unmarked unit is the cathode every time.)

T2 is a 2.5-volt, 10-Amp filament transformer to provide current for the I_{fwd} (forward-voltage drop) test. T2 could be a 5-volt winding on T1. However, I wanted to test high-current rectifiers so I used what I had available. D3 is a 50-volt, 25-Amp stud-mount diode. C3 is 10 μF at 30 volts and M3 is a 5-Amp unit. R7 gives me a full-scale reading of 3 volts on M2.

S3 is a rotary switch. It could easily be a DP3T slide switch if it can handle the necessary voltage. S2 is a DPDT center-off toggle switch, and if you buy only one part this should be it. It should be rated for whatever I_{fwd} you are designing for, and the center-off position is necessary for safety when using the unit. As a matter of fact, a momentary switch is not a bad idea even though operation would then be two-handed.

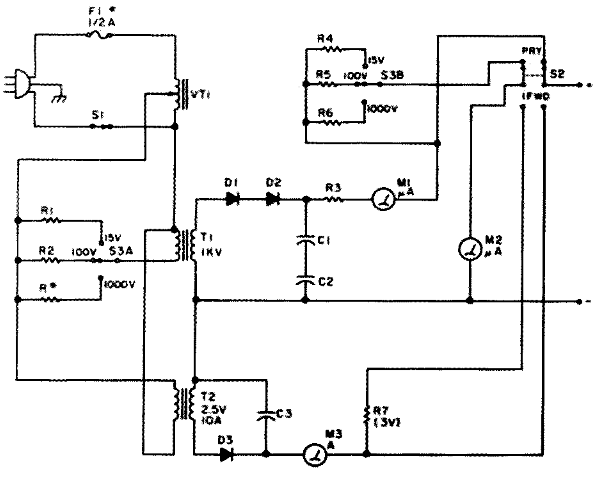


Fig. 1. The diode analyzer schematic diagram.

Construction Hints

1) Do not rush to your local parts house and buy all the parts. First, it would be expensive (the 2-Amp Variac is around $20 to $30) and, second, you will not have the opportunity for a good scrounging session.

2) Do not use chassis ground; use a ground bus instead. This will help prevent shocks.

3) Use a large container so that you will have room for future modifications and additions.

4) Group control functions in a logical arrangement.

Operation

For prv test, install a diode (cathode to positive), set volts adjust to minimum, set to lowest prv range, set range switch S2 to prv, turn on power, and advance volts adjust. If M1 goes off scale, reverse the diode connections and try again, advancing volts adjust and S2 range switch until a point is found where a very rapid increase in current occurs for a very small increase in voltage. This is the breakdown or zener point for the diode under test. The voltage, at the breakdown point, is the prv of the diode. Rate the diode well under the actual prv, especially in power-supply circuits.

If the diode under test shows a steady rise in current for an increase in voltage, discard it or use it in a noncritical use. It will become very apparent after testing your first handful of bargain diodes why they were priced so low.

For testing the forward-voltage drop (I_{fwd} test), turn off power, reverse the diode connections (cathode to negative), set volts adjust to minimum, switch to I_{fwd}, turn on power, and advance volts adjust until M3 indicates proper I_{fwd} for the diode under test. M2 will show the voltage drop across the diode. For a good silicon diode, this will be 0.4 to 0.8 volts, depending on the temperature and specific type of diode. Remember that the diode will be dissipating I × V power, so don't take too long for this test. It is possible to destroy the diode rather quickly.

If you test zener diodes, remember that the current will be limited by R3 to a very low value. However, the zener point will show up very clearly because M2 will rise to the zener voltage and refuse to go higher with an increase in the setting of volts adjust. M1 may go off scale under these conditions, so if you test zeners often, a shunt and switch could be added or a separate circuit could be added for testing zeners only.

This project has been well worth the time spent in construction and design. It provides a very worthwhile addition to my bench and has provided an extra bonus in that I use it as a source of low-current voltage and for checking leakage of unmarked capacitors. Last, but not least, I now know that when I install a diode in a project that its specs will meet the requirements of the circuit in which it is installed.■

Constant Current from a Voltage Regulator

Ever needed a constant-current supply? Recently, I needed a constant-current source to test some incandescent lamps as radio-frequency broadband noise generators. Rather than design an elaborate circuit, I decided to try using a simple technique by which a constant-voltage regulator can supply a constant current.

If a fixed resistor is placed across the output of a three-terminal voltage regulator, the current drawn from the supply is independent of the supply voltage. Hence, if the regulator circuit with fixed load is placed in series with any device, the current through the device will be constant and equal to the regulator output voltage divided by the fixed load resistance. The circuit configuration is shown in Fig. 1.

The output current is set by R1. For a 5-volt regulator, the output current is: $I = 5/R1$.

The maximum output current cannot exceed the regulator's output current rating. Hence, with a standard 7805 or LM309K, R1 should not be smaller than 5 Ohms. The power dissipated by R1 is 25/R1. The wattage rating of the resistor should be at least twice this value. The voltage drop across the regulator is the supply voltage minus the load voltage and must not be permitted to fall below 7 volts. The supply voltage must therefore be greater than 7 volts plus the load voltage or: $V_S \geqslant 7 + R_L I_{reg}$.

If the difference between the supply and load voltages drops to less than 7 volts, the current will no longer be constant but will decrease. This can be seen in Fig. 2, where the output current as a function of supply voltage for different load resistances is plotted.

One caution: Do not let the supply voltage exceed the input voltage rating of the regulator chip, which is usually 35 volts. Since I first tried this technique, the circuit also has been used to stabilize the current to a CW laser diode system where I work. ■

The Hesitator: A Windshield Wiper Control

—a rainy day project

This article is for the amateur who wants to make an inexpensive electronic device, using an integrated circuit, for his own pleasure or as a gift to a friend or friends. It is a hesitation circuit for your automobile windshield wiper and will cause delays of 2 seconds up to 15 seconds in the repetition cycle of the windshield wiper. It's great for misty or very light rainfalls.

It was mounted in a small box, fitted behind the instrument panel, and mounted by the potentiometer-securing nut. The wiring changes require the cutting of one wire in the wiper motor circuit and the soldering of ground and 12-volt power leads. I've built three for my friends and one for myself; they work great.

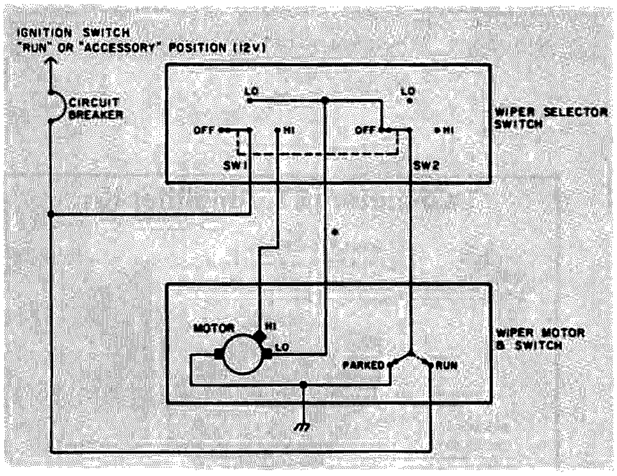

*Fig. 1. Automobile wiring circuit of windshield wiper control. The * indicates the point at which the hesitation control unit is installed.*

Automobile Wiring

The standard wiring for an automobile windshield wiper circuit is shown in Fig. 1. To understand the simplicity of the required wiring changes, let's go through the circuit. The ignition switch is in engine run or accessory position. To make the wiper motor run, it is necessary to have a complete circuit from 12 volts to the motor and then to ground. Notice that two switches are involved: the wiper selector switch, which permits selecting a low-speed, high-speed, or off position, and a wiper motor switch with parked and run positions.

In the off position of the wiper selector switch and parked position of the wiper motor switch, 12 volts cannot be supplied to the wiper motor.

If the wiper selector switch is turned to LO, 12 volts is supplied to the LO connection of the motor, then to ground, and the wiper motor moves the windshield wiper across the face of the windshield. When the selector switch is turned to HI, 12 volts is connected to the HI winding of the motor, which moves the windshield wiper at the higher speed.

Anytime the motor is running, it actuates an SPDT switch that alternately moves from ground to 12 volts. The ground position is known as the parked position and the 12-volt position as the run position. The run position takes up approximately 95% of the total time for one cycle of movement of the wiper.

When the wiper selector switch is moved to the OFF position, 12 volts is no longer applied to the motor from the SW1 contacts. If, as is the usual case, the wiper blades are not in the nest-

ed position at turn-off time, the wiper motor switch will be in the run position. While in this position, 12 volts will be connected through the switch, through the OFF position SW2 contacts of the wiper selector switch, and to the LO winding of the motor. The motor will continue to run until the motor switch is automatically moved to the parked position. At that time, voltage is no longer applied to the motor, and the wiper blades stop at their nested position.

To put in a hesitation control circuit, it is necessary to break and insert such a control at the point shown in Fig. 1. (See the asterisk.)

Fig. 2 shows the insertion of the control unit, which essentially is an SPDT switch contact operated by a relay, at that point.

In the unenergized condition of the relay, as shown, the contacts look like a straight-through connection, and the wiper selector switch is in control as already explained. (Keep the wiper selector switch in the OFF position.) When we momentarily (1/2 second, or so) switch the control unit contacts to 12 volts manually, the wiper motor will run and move the wiper motor switch to the run position. The wiper blades will make one complete cycle and return to the nested position. Power to complete the cycle is from 12 volts, through the wiper motor switch run position, the OFF position of wiper selector switch SW2, through the unenergized position of the control unit switch, and to the wiper motor. The motor stops when the wiper motor switch goes to the parked position.

All we have to do to make a hesitation controller is to devise a periodic short-term on-condition of its output so as to momentarily connect the LO motor lead to 12 volts to get it into a run/park cycle and to vary the time delay between repeating cycles.

Hesitation Control Unit

The hesitation control unit is designed around the faithful 555 timer. I learned how to use the timer from references 1, 2, 3, and 4. I know that there are a lot more articles on 555 applications, but these were enough.

Fig. 3 shows the schematic of the circuit used with the 555 timer in the astable, or oscillatory, mode. Two diodes in the timing circuit, CR1 and CR2, are used to select the charge and discharge times independent of each other's time constant.

Assume that the timing capacitor, C1, is charging towards 12 volts through CR1 and R1. The timer output (pin 3) will be high, and the length of time it is high is a function of R1 and C1. With the values shown, it is about 1/2 second. When C1 charges to the threshold trip level of the timer, both pin 3 and pin 7 go low. Then timing capacitor C1 will discharge to ground (pin 7) through CR2, R2, and R3. The length of time the timer is off is a function of the values of C1, R2, and R3. R3 is a potentiometer which is varied to control the amount of "hesitation" of the output. In the design shown, it is approximately 2 to 15 seconds. R2 is used to provide a minimum time delay when R3 is at its zero Ohms position.

As soon as the capacitor discharges to the lower trip level of the 555, pin 3 again goes high, completing the cycle. This oscillation continues as long as power is applied to the circuit.

For those who might want to change the above times: charge time = .67C1R1; discharge time = .67(R2 + R3)C1, where C is in farads and R is in Ohms.

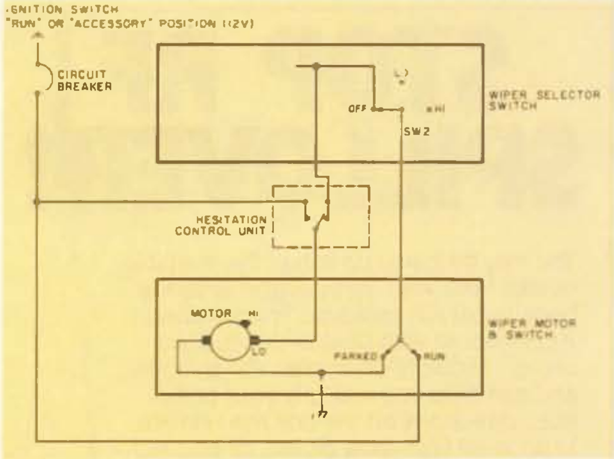

Fig. 2. Windshield wiper control with hesitation control unit added.

Because the relay which pin 3 drives is an inductive load, protective diodes are required to prevent the inductive kick at turn-off from latching or otherwise damaging the output of the timer.

Construction

Construction of the control unit was made as simple and inexpensive as possible. A chassis box 2-3/4" × 2-1/8" × 1-5/8" was used. Prepunched perfboard with holes spaced on a 0.1" × 0.1" grid measuring 1-3/8" × 1-7/8" was used as the mounting board for all components except the relay and its two diodes. The board was selected to permit an 8-pin IC socket to be used for the 555. The board was mounted on the back of the switch/potentiometer by drilling two holes in the board to clear the switch lugs. Using #16 solid wire to the lugs was sufficient to hold the board securely to the potentiometer/switch combination. Point-to-point wiring was used for the components.

The relay used is of the plastic-cased type. It was mounted to the box by removing its plastic cover and drilling a hole in the top of it to pass a #6 machine screw. The screw must be a flat-head type, with the head on the inside of the plastic cover. Use of a flat-head screw provides suffi-

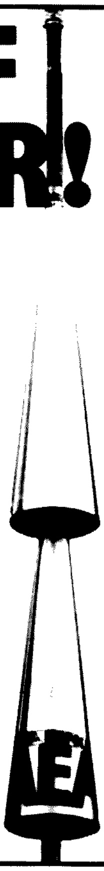
STOP RF SPILLOVER!

You may be losing up to half the available output from your vertical gain antenna because of RF spillover. The amazing AEA Isopole with unique decoupling design, virtually eliminates RF spillover and can help you multiply your power in all directions on the horizon relative to an ideal half-wave dipole, or end-fed non-decoupled "gain" antennas.



ADVANCED ELECTRONIC APPLICATIONS, INC.

✓2

AEA Brings you the Breakthrough!

cient clearance between the relay and the screw head. When the cover is reassembled with the relay, the whole thing is mounted on the side of the chassis box with an external nut.

Four connections are required between the control unit and the automobile: 12 volts, ground, motor, and switch. A solder lug secured under a chassis box screw was used for the ground connection. I could not find a suitable three-post terminal board, so I ended up using three phono jacks and plugs; it is nice to be able to disconnect leads in case maintenance is ever required. The potentiometer nut is used to secure the control unit to the instrument panel of the vehicle.

Testing

When the control unit is completely wired, check it with an ohmmeter between the positive power connection and ground to ensure that there are no shorts. Then connect 12 volts and ground to the proper leads, as well as a voltmeter between ground and the "motor" lead of the unit. Turn on the switch. The voltmeters should indicate an initial 12-volt reading, as C1 begins to charge, but it should last only about 1/2 second. If the potentiometer is left in the just-switched-on position, another 1/2-second pulse will occur about 15 seconds later. Turn the potentiometer fully clockwise, and pulses should occur every 2 seconds. Pulse pauses between the pot limits will occur at intermediate positions, providing an adjustment range to suit various damp to wet driving conditions.

Installation

The wiper motor usually is mounted on the engine side of the fire wall and on the driver's side of the car. To help locate it, try this: With the car engine off and the ignition switch in the accessory or run position, actuate the wipers. By feeling the running wiper motor, you can verify the fact you found it from the vibration on your hand.

It is necessary to identify two leads on the motor (there are usually four): the low-voltage lead and the 12-volt lead.

Most cars have a connector and plug at the motor; disconnect them. If there is no disconnect, the insulation of the leads will have to be cut to make voltmeter connections. With the ignition switch on and the wiper selector switch off, determine which of the four leads has 12 volts on it. That is the lead to the "run" connection of the wiper motor switch. It is always hot (12 volts) when the ignition is on and will be used to power the control unit.

Next, with the wiper selector switch in the low-speed position, determine which additional lead now has 12 volts on it. This is the lead which must be cut.

Now find a suitable mounting place for the control unit on the instrument panel. A 3/8"-diameter hole (or one to match the shaft of the pot you used) is drilled in the panel and the control unit secured by the nut on the potentiometer.

In addition, a hole through the fire wall must be found to pass the four wires connecting the control unit to the wiper motor. In some cars, a spare blank rubber grommet may be used by drilling a hole through it for the cable. In other cars, a large existing grommet may be drilled to pass the additional wires. If a new hole must be drilled, use a rubber grommet to provide a tight fit around the wires to prevent engine fumes from getting into the interior of the car.

Determine the wire length needed to go from the control unit to the wiper motor and pass them through the fire wall. Cut the low-speed motor wire and put solderless quick-disconnects on the two separated wires, as well as the two mating wires in the cable. The wire still connected to the motor goes to the "motor" lead of the control unit. The other cut wire is designated as "switch" and goes to that label on the control unit. The ground lead from the control unit is connected (or better, soldered) to a lug placed under a grounded screw on the motor.

The insulation of the hot wire (12 volts) must be removed over a 1/2", or so, length, and the 12-volt lead from the control unit soldered to it. Tape all leads and secure the cable in some manner so that it will not vibrate excessively. Cut off the excess length of the potentiometer shaft and put a nice knob on it. Now you can enjoy driving in a misty or slight rainfall instead of fiddling with the wiper switch. The adjustable wiper rate will keep the windshield clear without needless use of your wipers. You also will have the satisfaction that as an amateur you can make something "practical" to use or to give to your nontechnical friends. ■

TVRO Signal Source

—tuner-based test gear

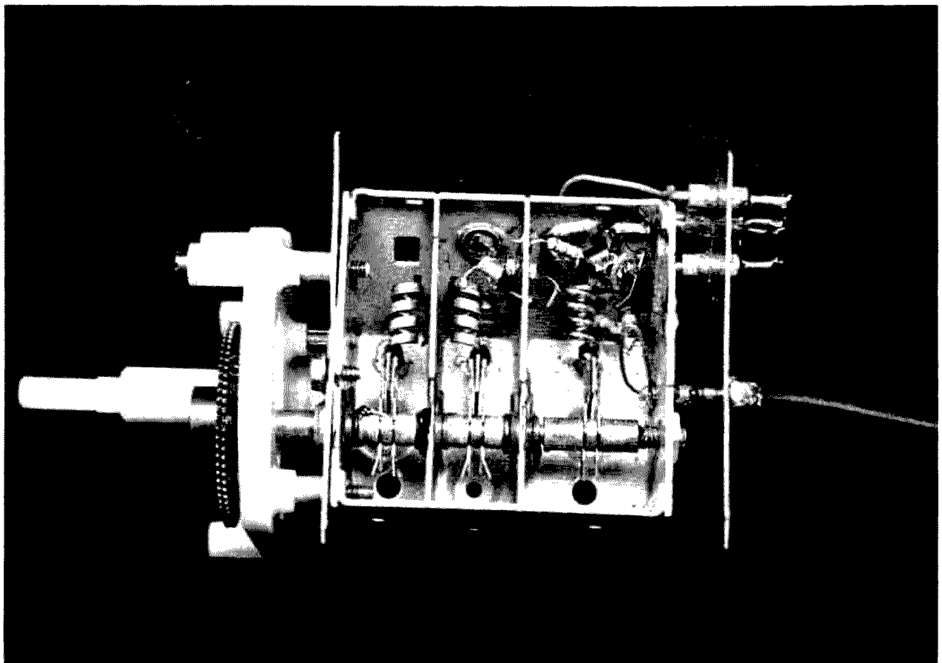

Photo A. Modified oscillator with front and back shields mounted. Bypass capacitors are mounted, and the brass ferrule passes the coax through the shield and the wall of the oscillator. Rf pickup loop can be seen.

In order to do any experimental work at UHF or microwave frequencies for amateur or TVRO projects, certain minimum equipment immediately becomes necessary. The first requirement for this work is to be able to generate known signals at these frequencies, to modulate, and to detect them. The use of microwave equipment from flea markets is not satisfactory because of its limited availability and its cost, and because relatively few units cover the frequency range of interest (500 MHz to 4 GHz).

The solution for the equipment problem turns out to be easy and inexpensive, with almost no debug problems. It consists of a modified UHF TV-tuner oscillator section followed by an harmonic generator. A sensitive detector is necessary for the low-power lev-

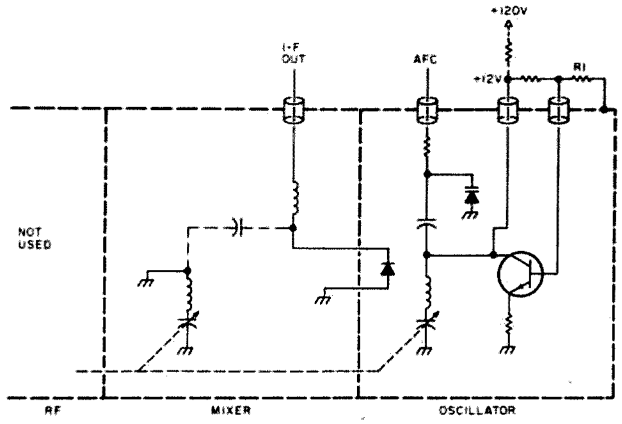

Fig. 1. Typical schematic of oscillator and mixer sections of UHF converters. Power supply is either 12 volts or 120 volts through a dropping resistor. The afc circuit can be used for frequency modulation or fine tuning, and the detector diode is used to monitor relative power output.

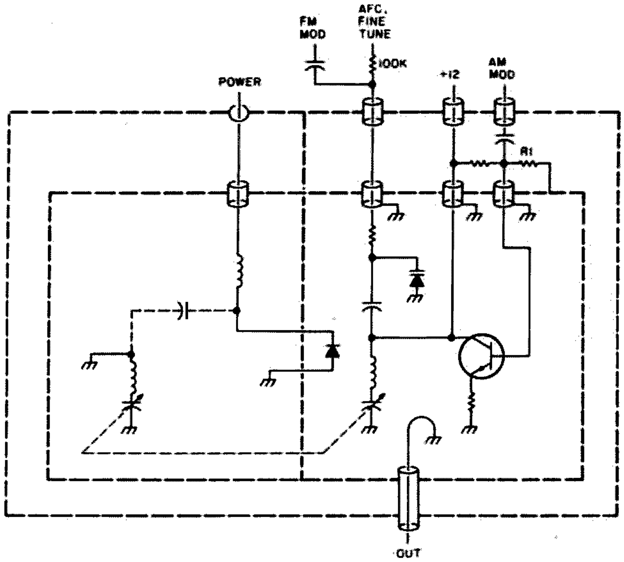

Fig. 2. Modified and shielded converter as used for a signal generator.

els involved, and this is easily found with a simple variable attenuator. The result is a signal source covering 525 MHz to 4.5 GHz with AM and FM modulation and video modulation on the low frequencies (525 to 1300 MHz), low level detection down to one microvolt, and afc or electronic tuning potential.

The construction requires only hand tools. The four basic units are modular and are reasonable weekend projects once the components have been obtained. Some general UHF techniques are outlined below which may be applied to make similar equipment more efficient.

Power-output monitoring on the fundamental frequency and a simple frequency calibration method also are described below, giving accuracy to about 1% without using a counter.

Generator

The generator consists of a modified oscillator section from a continuous-tuning type UHF TV converter. These are being sold surplus or may be recovered from an old TV set. One of the better units tested was salvaged from a 10-year-old TV set.

These units typically have the oscillator on the high side of the range, 45 MHz above the channel frequency, and cover about 520 to 930 MHz. Fig. 1 shows a typical circuit for the oscillator and mixer portions of the units. The design is simple, with minimum components for unwanted resonances, resulting in stable units. Some of the older units were found to have bimetal temperature-compensating elements. Otherwise, they nearly all have varactor diodes for afc frequency locking as shown in Fig. 1. The types with an afc diode provide easy FM capability and are the ones to use. All of the samples tested had good output which was relatively uniform over the band, dropping 3 dB at the high end. The two-speed vernier-dial mechanisms obviously help tuning.

The diode-mixer circuit coupled into the oscillator is used to check oscillation and output. It does absorb some power and may be cut out if not needed. The first section rf tuning closest to the shaft is disabled to minimize coupling rf out of the enclosure. Verify that the detector diode is all right by checking resistance at the phono-style connector. Forward resistance should be about 100 Ohms to ground. A 200-microampere-to-one-milliampere meter will read the output current.

Remove the cover of the tuner and by inspection find the voltage input terminal, the afc terminal, and, if accessible, the base bias terminal. Some units operate as grounded base oscillators, and the base is connected to a feedthrough capacitor with the bias network outside the case.

Power may be supplied in two ways, either through a 12k-to-15k, 2-Watt resistor limiting the current to about 10 mA, or directly from low voltage. The case is negative. A 12-V supply is used, and all units tested have oscillated, but the bias may have to be adjusted for uniform output and good modulation.

Use a series resistor of 2.7k to 3.3k to limit the current for an initial test of the oscillation with a 12-V supply. Current should be about 3 to 4 mA. The mixer-diode connection should show some current with the tuning capacitor fully meshed. A few microamperes indicate oscillation. If there is no output, increase the supply to 15 or 20 volts maximum for a test. If the detector diode is open, an rf probe can be made with a type 1N914 diode mounted directly on the terminals of a 50-to-100-microampere meter. Carefully probe the oscillator cavity for a reading. When oscillating with the cover removed, the signal should blank a UHF TV set at 10 to 15 feet without an antenna.

After the circuit is oscillating, remove the series-limiting resistor, apply 12 volts, and check for a reasonable and uniform output across the whole tuning range. Diode-mixer current should range from about 30 microamperes at the low-frequency end to perhaps 10 microamperes at the high end of the tuning range. Some oscillators have output as high as 100 microamperes. There should be no dead spots, with good output at the high end.

One oscillator with no high-end output was found to be biased incorrectly. It was discovered by af-modulating the transistor base through a small capacitor and observing the rectified waveform with an oscillo-

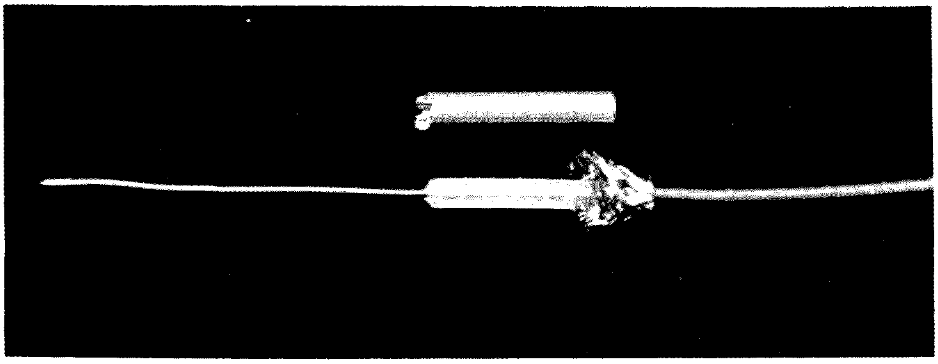

Photo B. Coaxial coupling cable and mounting ferrule before assembly.

scope. The modulating sine wave was badly clipped. To correct this, a variable resistor was substituted for R1 (Fig. 1) and adjusted for a good sine-wave output at low modulation level. A fixed resistor was then substituted for the variable. Linearity improved, and high-end output greatly improved.

Rf-output coupling for the generator is made with a small loop in the oscillator section. Two methods can be used for a connection. If no further shielding of the unit is used, a BNC connector is mounted on the rear wall of the oscillator cavity as shown in Photo A. Carefully drill a hole in the back plate to accommodate the threaded ferrule of the connector, as shown. A pick-up loop about 1/8 inch by 5/8 inches is positioned parallel to the tuning capacitor and soldered into the BNC connector. This works well. However, for low-level higher frequency work, adequate shielding is really required.

The rf field from the oscillator is strong, and some of the tuning openings cut in the tuner act as slot antennas at harmonic frequencies, making low-level work impossible. Consequently, a different coaxial method is used to pass through the printed-circuit-box shield.

This rf coupling consists of a ferrule made from brass tubing with an inner diameter equal to the outer diameter of the coaxial cable insulator, as shown in Photo B. An 8-inch length of RG-58/U is trimmed as shown, and the end of the tubing is filed with a notch for easy soldering. The ferrule and coax are mounted as the back shield is assembled.

The shield is made from printed-circuit material which, in the photographs, is 1/32-inch double-sided stock. However, a single-sided material can be used.

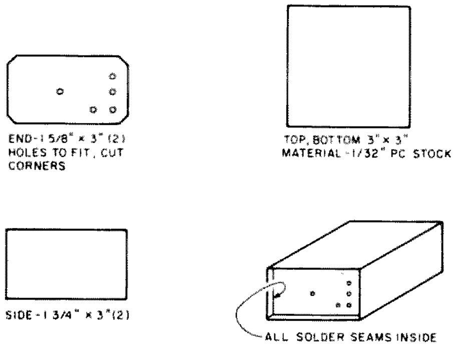

Fig. 3. Shield box dimensions. Actual sizes are determined by the tuner used.

77	853.75
(83)	(889.75)

Table 1. UHF TV channels and the frequencies of the sound carriers associated with them.

The parts are cut approximately as shown in Fig. 3, with the detail dimensions to fit the tuner. The front end is drilled for the tuning shaft and mounting screws, and the rear drilled for the coax ferrule and coaxial bypass capacitors.

Locate the rear-end piece so that the coaxial ferrule is aligned through both the shield and cavity. The ferrule is first soldered into the tuner. Then the rear shield is positioned as shown in Photo A and soldered. The coaxial cable is inserted so that the end of the insulation is just flush with the end of the ferrule. The loop is formed and soldered about 1/8 inch by 5/8 inches as shown. The fanned-out braid is soldered to the outside of the ferrule. This keeps the 50-Ohm impedance and eliminates rf leakage. Replace the tuner covers before shielding.

In order to avoid any unsoldered slots leaking rf, the sides of the shield are soldered on the inside corners (copper facing inward), and the end pieces are located inside the side pieces (copper facing outward) for soldering on the interior surfaces, as shown in Fig. 3. Each of the two side pieces is clamped in a right-angle holder for soldering. An iron with a long tip is invaluable. The larger the box, the easier the soldering will be. The 1/32-inch PC material can be cut with

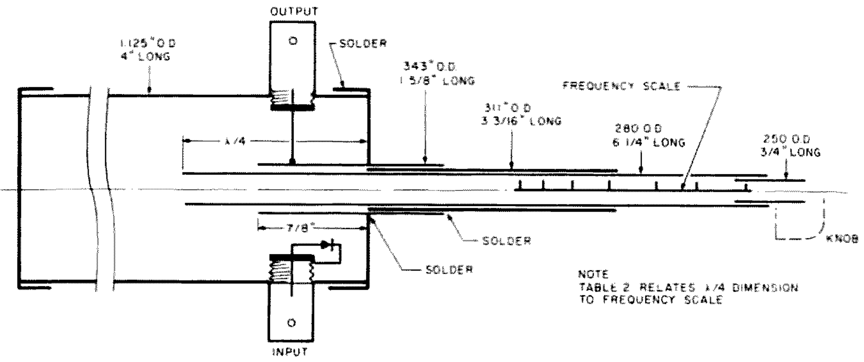

Fig. 4. Cross section of the cavity resonator used for the harmonic generator.

heavy scissors, which makes it easy to fabricate. The usual one-ounce copper PC material is OK because rf cannot penetrate it at these frequencies. When completed, the only hole in the shield should be the shaft opening, with the solder seams continuous.

The oscillator voltage should be limited to 12 volts and should be regulated with a good quality IC-type regulator for stability and low noise, although the current is only about 10 milliamperes. "Mostly AM" modulation is accomplished by capacitively coupling low-level audio or video, limited to about 0.1 to 0.3 volts, into the base of the transistor (Fig. 1). FM modulation is capacitively coupled to the varactor diode, as are the afc or fine-tuning voltages, if desired.

Dial and Calibration

A dial blank cut from clear plastic made a disc 4 inches in diameter. Two circles were scribed on the disk with radii of 1-1/2 inches and 1-3/4 inches to facilitate marking. A clearance hole was made through the disc, and then it was cemented to the hub of a cut-down tuning knob which fits the coarse-tuning shaft. See Photo C. The gearing ratio spreads the tuning over about 340 degrees, which gives a readable dial for the frequency range.

A TV set with detent channel tuning was used for calibration. This will give reasonable accuracy if the input is kept low enough so that the TV set afc doesn't pull the frequency very much to track the oscillator. Remove the TV antenna to keep the input low. A very low-level af signal at 500 to 1000 Hertz is used to FM-modulate the generator (Fig. 1). The TV set is tuned to a local UHF station and the audio tuned in with the fine tuning at the lowest possible signal strength. The TV set fine tuning is not changed during the calibration procedure. As seen from Table 1, there are TV sound channels on or near each 50 MHz within about 1%, except for channel 83 at the end of the dial.

Frequency	Quarter wavelength
1000 MHz	7.5 cm
1500	5.0
2000	3.75
2500	3.0
3000	2.5
3500	2.14
4000	1.875
4500	1.67

Table 2. Quarter-wavelength distances for coaxial cavity center conductor calibration. Refer to Fig. 4.

Mount the dial and cursor temporarily as shown in Photo C. The plastic dial is marked on the reverse side with a non-washable marking pen for neatness. For each 50-MHz dial calibration point, set the TV to the appropriate channel and then tune the oscillator down from the high side for a weak interference pattern (bars) on the screen. Then further carefully adjust the generator tuning until the sound is tuned in. The picture pattern should still be seen, so you will know that you are not tuned to the image frequency—which is 90 MHz lower. Repeat the procedure to check the calibration. The calibration marks should come out in a regularly-spaced pattern. Rub-on numbers can be used for the frequency settings on the dial.

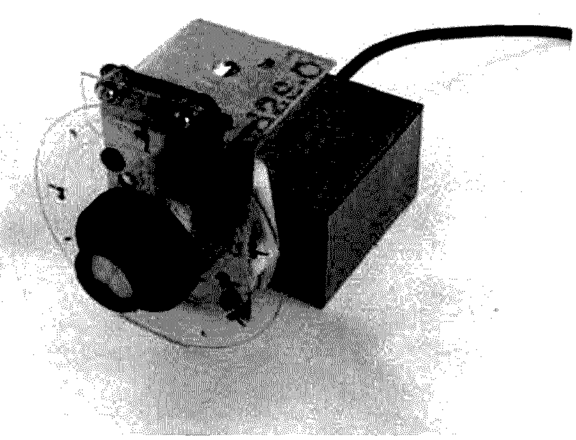

Photo C. Dial assembly with cursor temporarily mounted for calibration.

Harmonic Generator

A diode frequency multiplier is used in the harmonic generator to excite a wide tuning-range coaxial reentrant cavity resonator for the frequencies above 900 MHz. For easy fabrication, the center coaxial assembly is made of thin-wall brass tubing, available in hobby stores. It comes in successive concentric sliding-fit diameters from 1/16" to 5/8", with a wall thickness of about 0.015".

The outer tubing of the cavity is a brass toilet-overflow tube, 1-1/8" o.d., available in most hardware stores. The ends of the cavity are 1" copper-tubing caps which have an i.d. of 1-1/8". The caps are cut about 3/8" long with a hacksaw. A hole is drilled in the center of one piece for the center conductor of the resonator, as seen in Photo D. The dimensions of the cavity parts are shown in Fig. 4.

As a design aid for maximum efficiency in this type of construction, the following design rules were used.

1) For maximum Q, the ratio of the inner conductor o.d. to the outer conductor i.d. should be about 3.6, representing an impedance of about 77 Ohms.

2) Sliding electrical contacts are hard to make and harder to keep efficient. Therefore, use quarter-wave chokes at joints wherever possible. In chokes, minimize the spacing between the conductors (i.e., for low impendance).

3) The bearing sleeve for

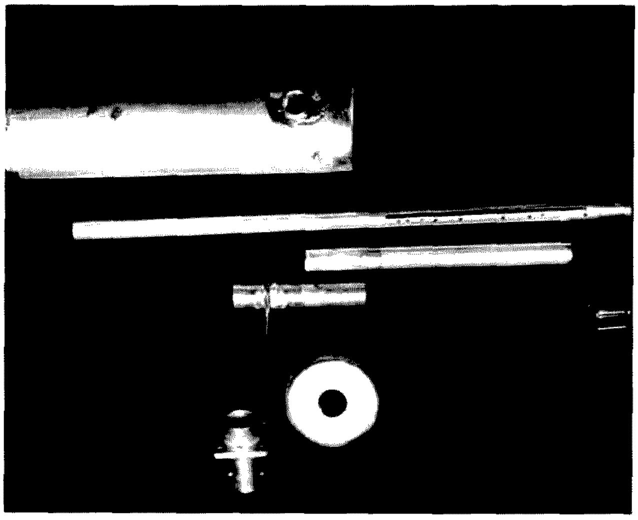

Photo D. Component parts of the harmonic generator prior to assembly. Only one BNC connector and one end cap are shown. The center conductor has been scribed for calibration.

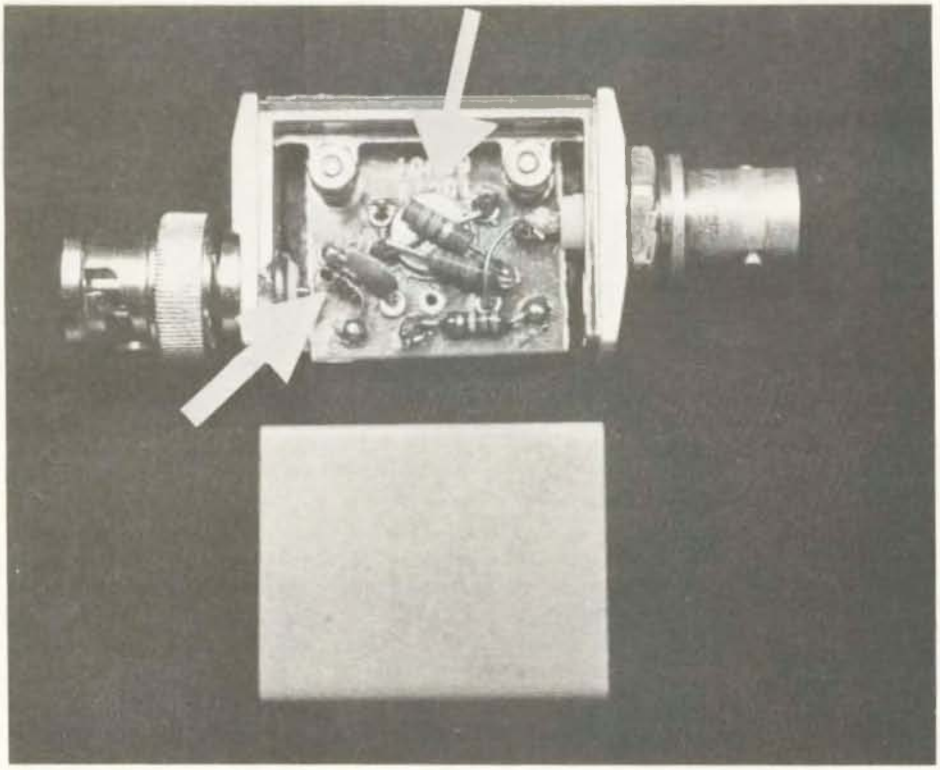

Photo E. Detector assembly. Arrows point to hot carrier diode and to the battery.

the adjustable center coax member is at least one-quarter-wavelength long at the lowest frequency used.

4) Allow about two diameters of the center-coax-member clearance to the end cap at the extended (low-frequency) position of the inner conductor. This reduces end effects which would affect the linearity of the tuning scale.

5) The rf feed-coupling loop is close to the short-circuited end of the cavity, and the ground end is returned to the BNC connector to reduce losses. The loop is actually the harmonic-generating diode. The loop size should be small compared to the wavelength to minimize frequency pulling.

6) If possible, have the interior of the completed coaxial assembly silver plated. A thickness of 0.0001" is adequate[1] and will not affect the sliding fit.

7) The output is tapped to the center conductor rather than loop coupled. This gives greater output (Photo D).

8) The copper and brass parts should fit well before soldering, and good low-loss soldering helps.

9) Several diode types were tried to get the best harmonic output without idling circuits. The best output came from selecting diodes of the 1N914 type. Idling circuits were not used, to simplify tracking when changing frequency.

The parts of the cavity were cut to size and assembled loosely to position, and file notches were made to locate the assembly positions while soldering. Pre-tin the mating surfaces to help the solder flow. The threaded cable bushings for the BNC connector are first inserted from the inside of the cavity wall, as seen in Photo D. The output connection wire is insulated with a piece of coax center insulator cut to length and inserted before final assembly.

The brass tubing is not hard enough to make contact fingers, but a contact improvement can be made to more sharply define the tuning. In order to do this, slightly compress each end of the coax support bushing by rotating against a flat or in the jaws of long-nose pliers. This cold-working tends to make a tight fit on the sliding center coax conductor. Wear life is limited, but it gives some improvement in output.

Detector

Several types of diodes were compared for best sensitivity, including 1N914, microwave 1N21, and TV-mixer diodes. The

Photo F. Harmonic generator assembled.

Photo G. Attenuator assembled.

best sensitivity was obtained from hot carrier diodes with a small amount of forward dc bias. These diodes developed as much as ten times the rectified af signal of the other types. Both Motorola HEP R0700 and Hewlett Packard 5082-2835 types worked equally well. Since then, Radio Shack has the 5082-2835 type as their part number 276-1124. A forward bias of about 0.25 volts works best, and the maximum forward voltage is 0.340 volts. The output without bias is very poor. Note also that these diodes are very sensitive to damage by electrostatic discharge.

The circuit is shown in Fig. 5. A small mercury watch battery is used in a voltage divider to develop the bias. The current drain is low, and the battery is not switched. The diode must have a dc return connection through the input circuit.

The detector assembly was built into a small mount with BNC connectors salvaged from a scope probe—see Photo E. The battery was mounted within a clearance hole drilled in the PC board, and bridging wires were soldered on either side of the PC board about 90° apart to make contact and to retain the battery. This can be seen in the photo.

The output level of the detector depends on the modulation used. With amplitude modulation on the generator, the rectified signal can be seen on an oscilloscope or detected with an audio amplifier and speaker. The scope response needs only to be sensitive to the audio frequency used, but it should be high impedance. In this way, 5 to 10 millivolts of modulated signal is easily read at the 4th or 5th harmonic, whereas it is extremely difficult to detect an unmodulated signal above the second harmonic.

In use, the harmonic generator is adjusted for the output frequency desired with AM, and then the desired modulation is used.

Attenuator

The attenuator is a waveguide-beyond-cutoff type.[2] A coupling loop lying on a diameter of a circular waveguide propagates a wave which the guide cannot support and, therefore, it is attenuated. A similar coupling loop at some distance down the waveguide picks up the energy. If the waveguide diameter is small compared to the wavelength, the relative attenuation is proportional to the separation of the loops. It is relative because of the difficulty in setting a "zero" in the vicinity of the loops. The loops must lie in the same plane and, to avoid reflections, must be terminated in the line-characteristic impedance.

For a circular waveguide, the cutoff wavelength of the lowest mode propagated is 1.71 times the diameter. For 4.2 GHz, this would be a diameter of 12.2 cm (4.8"). Therefore, an attenuator with a diameter of about one centimeter satisfies this condition. The attenuation is 31.9 dB per diameter[2] under this condition, provided the coupling loops stay in the same plane and no harmonics are transmitted. The closed harmonic for this size pipe is about 17 GHz.

Because of the end effects, the closest coupling should be about one diameter, which sets the 0-dB point at about 30 dB below the input.

The ratio of tubing diameters should be 2.31 times for 50-Ohm impedance and 3.49 times for 75 Ohms. Using tubing with an i.d. of 0.466", the 50-Ohm center conductor should be 0.188", and, for 75 Ohms, 0.124".

The tubing parts are cut to the dimensions shown in Fig. 6. Cutting is easy if a ring is filed around the tubing and the section snapped off. Small model maker's files are excellent for this. The metal film load resistors have one lead cut off, and the end is scraped so that it can be tinned and then soldered to the center conductor. The larger tubing is then soldered to the BNC fitting flange, and the ground end of the resistor soldered.

The "hot" end of the sliding tubing is expanded slightly to provide some friction-fit to the inner diameter of the barrel, as was done with the coaxial cavity parts. Small brass hinges are used to make a large hinge, preventing relative rotation of the two ends of the attenuator, as shown in Fig. 6. A relative attenuation scale is marked on the inner barrel, with the zero at about one diameter. The major marks for 30-dB intervals are separated by 0.438" (1.11 cm), and the 10-dB marks by 3.7 mm. The scale was scribed on the brass and the marks inked in.

The hinges can be omitted if the attenuator ends can be kept flat.

Conclusion

An inexpensive low-power generator has been described for the UHF and low microwaves. This generator has capability for beginning the TV and FM signal requirement at these frequencies. The component parts are modular, easy to operate, and may be used in other applications or with other pieces of equipment. The harmonic generator can operate as a wavemeter, and the attenuator will work at lower frequencies. The shielding is effective in limiting stray signal radiation. Some design parameters have been given, which may be applied to other similar equipment for these frequencies. ■

Satellite Television Glossary
—part II

Editor's Note: Reprinted with permission of Reed Publications. This glossary is part of the 86-page *Satellite Television Handbook*, available for $7.95 (add $2.00 for 1st class) from Global TV, PO Box 219-H, Maitland FL 32751. Part I of this glossary appeared in the December, 1981, issue of *73 Magazine*.

Margin. A 3-dB increase over the FM threshold, in a TVRO system, of the C/N which will provide an output signal completely free of impulse noise (sparklies). The FCC set this figure when CATV Earth stations were more strictly regulated.

MATV (Master Antenna Television). High-quality UHF and VHF antennas centrally located can provide TV programs for an entire apartment complex, condominium, or townhouse development. These signal distribution systems differ from CATV installations chiefly in size and degree of profit.

MDS (Multipoint Distribution System). This works like a cable system without the cable; a central microwave transmitter at 2 GHz is used to distribute one or two channels of pay TV to subscribers who have roof-mounted dishes and downconverters. The power of the transmitter is so great that the entire receiver is much less expensive than a TVRO. The MDS systems are regional, mostly in the southwest USA.

MHz (Megahertz). The standard abbreviation for millions of cycles per second. Henri Hertz was a famous scientist who pioneered wireless communications.

Microprocessor. A stored-program computer on a chip which can replace ordinary circuit parts and add functions to some manufacturers' receivers.

Microstrip. An improvement of an earlier microwave assembly technique called stripline. Double-sided microwave PC boards have etched upon them transmission lines and inductors. Capacitors and active devices may be soldered on as well.

Mixer. That part of a downconverter which joins together an input signal with that of an LO (local oscillator) to create an output signal which has a frequency that is the numerical difference between the two input frequencies. The program material in the FM carrier is not affected by the mixing process to a lower frequency.

MPAA (Motion Picture Association of America). A Hollywood trade organization which represents the film industry, assigning movie ratings and controlling movie distribution to some extent.

MTBF (Mean Time Between Failures). This is the average elapsed time before samples of a manufacturer's product fail. It is a measure of the reliability of the part.

MTTR (Mean Time To Repair). This is the average down time for a broken part. It measures the ease of repair and is used when considering the possible consequences of the part failing.

Multistage LNA. Three or more transistor amplifier stages are placed end to end (cascaded) so that the gain contribution of each one will add up to approximately 50 dB. In most LNAs the first stage, closest to the antenna feed probe, has the best noise characteristics to minimize the noise propagated along through the remaining stages.

N Connectors. Coaxial cable fittings which interface cables between the LNA and satellite TV receiver. They carry 4-GHz signals at 50 Ohms impedance with low loss.

NAB (National Association of Broadcasters). A trade organization of network affiliate VHF/UHF broadcasters.

NF (Noise Factor). This measures the thermal noise contribution of LNAs and receiver front ends. LNAs typically measure 1.5 dB (120° K) and receivers average 11-15 dB.

NTSC (National Television System Committee). The method of forming a color TV signal that is used in the western hemisphere with few exceptions. NTSC is also the Japanese standard. It has 525 lines per frame and 60 fields per second.

Octave. A measure of frequencies which differ by a factor of two in wavelength.

Orthomode Coupler. A section of waveguide such that two LNAs can be attached at right angles and simultaneously receive both horizontal linear and vertical linear polarized satellite TV programs.

Orthogonal Mode Coupler (or Transducer). See *Orthomode Coupler, above.*

P-P. Peak-to-Peak measurement of a waveform's amplitude as opposed to rms (root mean square), which is otherwise implied.

Packaging. This is the boxing of various circuit parts in a module. Typical ICs are packaged in DIPs (Dual Inline Package) with two rows of pins to fit sockets on the PC board.

PAL (Phase Alternation System). A European color TV system featuring 625 lines per frame and 50 fields per second. Generally this method gives higher resolution TV pictures than the American NTSC (525-line) color system. No PAL is broadcast from American or Canadian satellites but it may be found on INTELSATs.

Parabolic Dish. This antenna shape is commonly used to focus all the microwave energy collected on the dish surface into a single point in front of the dish called the focal point. It can be built from metal sheets, fiberglass, mesh, or wood covered with a metal reflecting surface which is accurate, with respect to a perfect parabola, to within 0.1 inch.

Passive Elements. Electrical components which do not include transistors and cannot amplify the signal. Examples are capacitors, resistors, diodes, inductors, most mixers, and transmission lines.

Path Loss. The loss incurred in a satellite TV signal from the transmitter to the receiver, while in space. Path loss can be measured on either the uplink or downlink path.

Parametric Amplifier. A complex form of LNA which depends upon a high-frequency source (Gunn-effect pump) rather than a dc source to amplify the weak input signal. It works like a MASER. The input signal modulates an electron beam and the pump amplifies it while it travels to the output coupler. These can be cryo-cooled to yield ultra low noise temperatures down to 20° K. Parametric LNAs are much more expensive than GaAsFET LNAs.

PC (Printed Circuit). An easily-made dielectric board on which nearly all the conductors and interconnections are laid out on the surface in thin copper strips and the assembly of the finished products is reduced to soldering on the parts. The wiring step is greatly reduced.

Phase. A relative position of an oscillating signal in full circle coordinates. 0 degrees is just starting, 90 degrees is one-quarter of the way through, 360 degrees is back to the starting point. Two signals are in phase if the phase difference is zero and the peaks and valleys match.

Phased Array. A technique of improving the gain of an antenna system by combining the outputs of several similar VHF/UHF/FM antennas in an array taking care that the output signals from each one are exactly in phase with one another.

PLL (Phase-Locked Loop). One form of FM demodulator which employs a feedback loop to lock a local oscillator to the same frequency and phase as the input signal. The error corrections applied back to the LO are equal to the original program signal that modulated the carrier and are passed through the circuit as the output.

Polar Mount. An antenna mounting and aiming system in which one pivot is positioned one time only and the other pivot (hour axis) is positioned to sweep the satellite arc. Some fine adjustments may be required on the first pivot (declination axis) but this mount is much easier to aim than the azimuth-elevation mount.

Polarization. In order to increase the capacity of TV satellites, transponder frequencies overlap but alternate between vertical linear and horizontal linear polarization. The dish feed and satellite feed polarizations must match or the signal will be lost. Feeds on dishes rotate 90 degrees in many designs or an orthomode coupler allows two LNAs to get both polarizations simultaneously. INTELSAT uses right-hand circular or left-hand circular polarization. Use a hybrid mode feed to receive them.

Port. A physical signal interface. This can be a waveguide flange or connector.

Potted. A form of electronics packaging in which the part is immobilized in plastic.

Power Amplifier. An active device which features a high-level signal output as opposed to an ultra low noise figure. *For comparison see Preamplifier below.*

Power Divider. A passive device similar to a signal distribution splitter but used at 4 GHz to split an LNA's signal for up to 12 separate channels (either all vertical or horizontal). A full-channel CATV or MATV system would require two LNAs and two power dividers to drive 24 separate receivers.

Preamplifier. A class of active devices in which LNAs are included and that feature low noise performance as opposed to high-level signal output. They amplify (strengthen) the signal before it reaches the relatively noisy receiver front end.

Pre-emphasis. A selective amplification of the high frequency end of a satellite TV channel prior to uplink transmission to overcome potential noise problems. Each satellite TV receiver reverses the transformation in its de-emphasis circuits.

Prime Focus Antenna. A parabolic dish antenna in which the LNA is located out in front of the dish at its focal point. This type of feed design is generally the least expensive.

Private Terminal. A TVRO which is not associated with CATV but is for the benefit of a private individual viewer.

Probe. The driven element in a microwave dish antenna system. It is located in the feed and converts rf energy in the waveguide to a signal on a transmission line to the LNA.

Program Control Tones. Telephone-style audio tones preceding and following many satellite TV programs which control automatic program selection equipment used by CATV.

PWM (Pulse Width Modulation). A method used in

USSR TV satellites to encode the audio signal between the video lines of the composite TV picture.

Quieting Curve. A graph of the signal-to-noise ratio (S/N) versus the carrier-to-noise ratio (C/N) for a particular satellite TV receiver. Generally for C/N above 8 dB, S/N = C/N + 38. The point on the curve below 8 dB C/N where S/N rapidly falls off is the FM threshold.

Registered TVRO. The FCC accepts registered Earth stations so that it can be protected from possible terrestrial interference. Frequency coordination must be performed as part of the registration procedure.

Regulated Power Supply. A dc power supply which is designed to prevent minor fluctuations in line voltage from propagating into the dc output.

Resolution. A measure of detail reproduction in a TV picture which improves with increasing S/N. It is also a function of the number of scanning lines in a frame. The European color system (PAL, SECAM) has 625 lines and better resolution than the American (NTSC) 525-line system.

RFI (Radio Frequency Interference). Any electrical spurious signals in the i-f range causing static and noise in a receiver. RFI can also be caused by improperly shielded components within a receiver.

RMS (Root Mean Square). A method of measuring the average power or voltage in a sine-wave signal. *See P-P for comparison.*

Rotor Systems. A method of rotating an LNA feed 90 degrees to switch between vertical and horizontal polarizations. Many times an antenna rotor can be used with remote control from indoors.

S/N (Signal-to-Noise Ratio). A TVRO measure of picture quality expressed in dB. Broadcast studios try to put out signals above 50 dB S/N, CATV supplies 45-50 dB S/N, and typical VTRs have an S/N of 45 dB. Watchable pictures go down as far as 40 dB S/N. One or two dB above the C/N FM threshold of a satellite TV receiver will put a TVRO into the 45-dB S/N range for fine pictures.

SATCOM F1. American TV satellite operated by RCA to supply most of cable TV programming on 24 transponders (12 are vertical and the other 12 are horizontally polarized). Also referred to as just F1, it is located at 135 degrees west longitude.

SATCOM F2. American TV satellite operated by RCA to supply assorted video and data programming to Alaska and other points in the USA. Like its sister, F1, it has 24 transponders. It is located at 119 degrees west longitude and can be also referred to as just F2.

Saturated Transponder. A satellite TV transponder which is operating at full power. They do not have agc circuits, so the output transponder power is proportional to the received signal from the Earth. Sometimes the uplink signal is backed off so that the transponder will have a longer useful life. In that case, EIRP levels on the Earth will also be proportionally lower.

Schottky Diodes. High-frequency solid-state rectifiers used to build microwave mixers.

SCPC (Single Channel Per Carrier). One stream of data or programming on a satellite communications carrier as opposed to multiplexing many voice or data subchannels within a given carrier frequency. Mostly used for voice (telephone), many separate carriers having different frequencies can fit into a 36-MHz-wide satellite transponder.

Scrambling. Techniques to encipher a TV signal to prevent unauthorized reception without a descrambler device. Typically this is done by coding the sync information of the video signal. None of satellite TV for CATV use is scrambled.

SECAM (Sequential With Memory). A French color TV system with 625 lines per frame and 50 fields per second. It is also used in the USSR.

Sensitivity. This performance parameter measures the input signal required to produce an adequate picture from a satellite TV receiver.

Shielding. The design process in which electronic components are protected by sheet metal or other conductors from spurious signals. Coaxial cables are shielded by the outer conductor, which is grounded.

Shrouding. Protective walls or screens around a dish antenna which stops side interference. It is not needed at most Earth-station sites.

Sidelobes. Areas from which noise can leak into a dish antenna from the side. Sidelobe performance is the ability of a given dish to reject these in favor of the satellite signal.

Signal Combiner. This is the reverse of a signal splitter. It allows several TV signals on different channels to be merged onto a single broadband transmission line. Many times this device can be substituted for by a signal splitter connected in the reverse direction.

Signal Distribution System. A network of signal amplifiers, splitters, and cables bringing satellite and off-the-air TV to a number of separate TV sets. Usually all the parts are 75-Ohm devices with baluns to convert to a TV set's 300-Ohm antenna terminals.

Signal Splitter. This is a passive device which enables two or more TV sets to divide a TV signal between them with proper balancing and isolation. It can be supplied in either 75- or 300-Ohm impedances.

Signal Trap. A passive device which filters out a selected channel. This can be used to control the distribution of a premium (pay-TV) channel or to remove a source of interference.

Single Conversion. This technique uses just a single local oscillator and mixer to convert a satellite TV signal from 3.7-4.2 GHz down to the final i-f (usually 70 Hz). Lower parts count and ease of assembly are important advantages over double conversion but care must be taken to prevent noise on the image frequency from leaking into the output.

Sky Noise. Background microwave radiation coming from deep space which can be a noise source for dish antennas. Sky noise provides a lower boundary for the possible noise temperature of any dish antenna and is approximately 16-20° K.

SMA Connectors. Miniature fittings to conduct signals between parts of a downconverter using small circular waveguide.

Snow. Dot-type TV interference associated with weak signals in UHF/VHF TV pictures. *See also Sparklies.*

SNR. See *S/N.*

Solar Interference (Outage). Twice each year, the sun's path will position it behind the TV satellites in a direct line of sight with TVROs. Care must be taken to prevent concentrated heat from cooking the delicate LNA at this time if a prime focus antenna is used in a TVRO.

Space Attenuation. The loss in a TV satellite signal due to the fact that the beam spreads out after leaving the antenna. This is a major factor in path loss.

Sparklies. Weak signal noise which appears as a dot or streak interference in a satellite TV picture. Loss of lock in an FM video demodulator causes this, and in extreme cases tearing or loss of the picture will result.

Spherical Antenna. This is an alternate form of dish antenna, easy for the layman to construct and having a circular cross-section instead of a parabolic one. Another feature is the ability to employ multiple feedhorns in front of the dish to receive signals from up to 10 TV satellites at once within a 40 degree orbital arc. Its design was invented by Oliver Swan.

Spot Beam. An antenna downlink pattern which provides a continent-sized footprint for an INTELSAT satellite. Generally the term describes any narrow satellite beam confined to a specific relatively small area.

SPTS (Satellite Private Terminal Seminar). An industry educational and trade show conducted three times a year in various locations by Robert "Coop" Cooper.

Stability. The ability of a tuning circuit to avoid drift that most often is caused by ambient (surrounding) temperature changes. Lack of stability is the main reason that afc circuits are used in satellite TV receivers. Crystal control provides the best stability. The term is also used to describe the ability of an amplifier to resist feedback of the output signal around to the input side. Home-built LNAs may become unstable and begin oscillating if leakage is not prevented.

Sweep Generator. A test-equipment device which creates a signal evenly over a range of frequencies. They are used to align frequency-sensitive components such as filters.

Sync Pulse. Sync is an abbreviation for synchronization. Horizontal and vertical oscillators lock on these spikes in a TV set. It is part of the video picture information in the composite TV signal.

Tearing. A form of weak signal interference which causes ragged streaks on the TV picture in vertical lines joining light to dark transitions. If this occurs in a satellite TV picture it is a good indication that the receiver is operating well below FM threshold.

Termination. A connector or passive device at the end of a signal transmission line. This is like an end cap to maintain the impedance of the line.

Terrestrial Microwave. Communications links on the ground using microwaves. One of the allowed ground frequencies is the same as the band allocated to TV satellites, and frequency coordination is needed by commercial TVROs to resolve conflicts.

Test Equipment. Auxiliary electronic signal generating and measuring devices used to tune and troubleshoot electronics equipment, including LNAs and satellite TV receivers. Some of these are: sweep generators, signal generators and markers, frequency counters, volt-ohmmeters, and oscilloscopes.

Test Pattern. This color bar pattern helps satellite TV technicians properly maintain uplink and downlink equipment. It seldom appears on VHF/UHF TV, but on TV satellites it occurs when a transponder is unused.

Threshold Extension. A circuit technique, sometimes located in the loop filter of a phase-locked loop demodulator, which improves the low signal performance of a receiver by lowering the FM threshold by 3 dB C/N.

Tilt Attenuator. A form of signal attentuator which compensates for the fact that high frequency signals lose more strength than low frequencies over a given run of transmission line. One of these is inserted into a signal distribution system just before a trunk-line amplifier.

Translator. A TV repeater which operates on UHF channels 70 to 83 (806-890 MHz). It retransmits ordinary broadcast TV to areas which cannot get direct reception.

Transients. Fluctuations in power supply voltages which can cause noise in a receiver and sometimes, if powerful enough, can damage delicate transistors in the LNA or receiver.

Transponder. Satellite hardware which implements a channel. It consists of a receiver 36 MHz wide in the 6-GHz uplink band and a broadcast transmitter 36 MHz wide on the 5-GHz downlink band. TV satellites have 12 or 24 transponders.

Turnkey. An equipment supplier who installs everything for the end user who only has to "open it with his key." This is the most expensive but most professional installation method.

TVRO (Television Receive-Only). Acronym for a satellite TV receiver (Earth station) consisting of dish antenna, LNA, and one or more receivers.

Tweaking. Tuning by hand to optimize performance of a circuit after assembly. Also called alignment.

Twinlead. A 300-Ohm transmission line to carry TV signals to the set. It is made in the shape of a flat ribbon, having lower losses than coaxial cable (coax) but being less resistant to rf interference.

TWT (Traveling Wave Tube). A high-power microwave amplifier on board TV satellites. Each transponder has one.

UHF (Ultra High Frequency). TV channels 14 through 83 (470-890 MHz), which are 6 MHz wide.

Ultra Low Noise LNA. See *Parametric Amplifiers.*

Uplink. The Earth station which transmits TV programs to the satellite for relay back to the ground. It is also the name for the communications path from the Earth to the satellite.

Vco (Voltage-Controlled Oscillator). A signal-generating component which provides an input to the downconverter and demodulator portions of a

satellite TV receiver. The oscillator's frequency is determined by an applied voltage.

VCR (Video Cassette Recorder). *See VTR.*

VHF (Very High Frequency). TV channels 2 through 13 in the following bands: channels 2-4 occupy 54 through 72 MHz, channels 5-6 occupy 76 through 88 MHz, and channels 7-13 occupy 174 through 216 MHz.

Video Monitor. A high-quality television screen lacking a tuning circuit which accepts video baseband inputs directly from a TV camera, VTR, or satellite TV receiver with no modulator required. They are not mass-produced and are ironically more expensive than TV sets of the same size.

Vswr (Voltage Standing Wave Ratio). A measure of the efficiency of a signal interface, especially the impedance match of the antenna to the LNA.

VTO (Voltage-Tuned Oscillator). *Also called a Vco (see above).*

VTR (Video Tape Recorder). A useful adjunct to a satellite TV system.

ITU (International Telecommunications Union). Deals with timely issues such as frequency band allocations worldwide.

Waveguide. A microwave conductor shaped in the form of a rectangular tube to prevent signal loss. Size WR229 is used for 3.7-4.2-GHz satellite TV signals. It can be pressurized to remove ambient moisture and further increase its performance.

West Coast Feed. Satellite TV programming time shifted and broadcast primarily for the benefit of west coast viewers. If one misses a favorite movie on the east coast feed, he can watch it four hours later on the west coast transponder.

WESTAR I. American TV satellite operated by Western Union. It has only 12 transponders and is located at 99 degrees west longitude.

WESTAR II. American TV satellite in the WESTAR series located at 123.5 degrees west longitude. It also has just 12 transponders.

WESTAR III. American 12-transponder TV satellite in the WESTAR series which is located at 91 degrees west longitude.

Wind Loading. The force upon a satellite TV dish and supports caused by air pressure. Generally, a dish should be able to withstand 120 mph (193km/h) and be able to sustain a 40-mph wind without damaging the picture.■

HAM HELP

I need instruction manuals and schematics for a Singer/Gertsch frequency meter (model FM-6) and a Hickok model 670 oscilloscope. I will promptly reimburse with thanks for loan to copy or copying costs.

Leslie W. Bruce W0OX
335 S. 40th Street
Boulder CO 80303

I am in need of a schematic for a Sideband Engineers model SB-450 transceiver. I will be glad to pay duplicating and mailing costs, or I will duplicate on receipt and send back by mail.

Alex Haynes
2703 Hambleton Rd.
Annapolis MD 21140
(301)-956-2302

I would like to obtain information from other radio amateurs on two-meter repeater locations in New England. I am in the process of compiling a listing of two-meter repeaters in New England showing exact locations (mountaintops, buildings, etc.). Other information such as autopatch capabilities (access codes not necessary), RACES affiliation also are wanted. Glad to share information with anyone interested.

Ed Soomre N1BFF
1 Alcott Drive
Northboro MA 01532

I need a copy of the scanner circuit that was popular for the HW-202 in 1975. Mine has stopped working.

Gordon Lauder W9PVD
Rt. 2
Webster WI 54893

I am collecting club bulletins from all over the world. Who will send me a copy of his club bulletin? I'll send ours plus postage costs.

Going Bird Hunting?

—Satellite Central, part III

Stephen Gibson
PO Box 38386
Hollywood CA 90038

Aside from making your equipment work, finding the satellite may be your biggest problem. Typical dish-antenna beamwidths run less than 2 degrees, so you may end up scanning the skies for hours. You can cut the job down to only a few minutes, however, if you know the location of the satellite relative to your particular location. Here's how to do it.

By now you know that most of the interesting TV satellites are located in geosynchronous orbit above the Earth's equator. The idea of equatorial satellites is not new. In fact, this ideal coverage spot was suggested nearly 37 years ago by famed science-fiction writer, Arthur C. Clarke, who published an article in *Wireless World* called "Extra-Terrestrial Relays." Fancy that! It's taken some time for the idea to catch on. Bob Cooper W5KHT suggested that we name the belt after Clarke. Good idea.

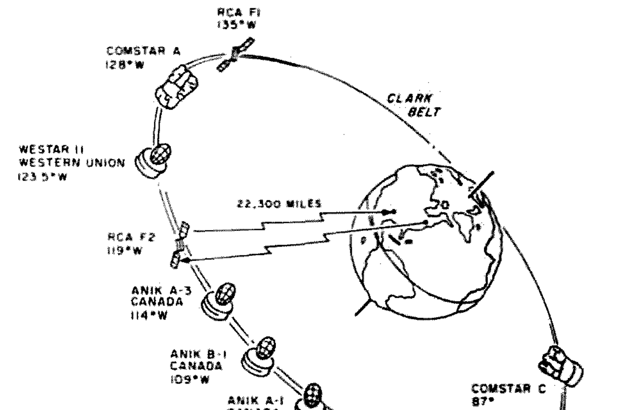

Fig. 1. Geostationary satellites. Clarke-belt satellites circle the globe above the equator at the same rotational speed as the Earth. They appear to us as fixed points in the sky, which simplifies antenna pointing.

Can we see Clarke-belt satellites as we did Sputnik? You'd have to really squint because they orbit the Earth nearly 22,300 miles out! To an observer here on Earth, the satellites in Fig. 1 appear to be standing still because they circle the Earth every 24 hours . . . and in the same direction. This makes tracking a piece of cake. Just point the dish and walk away, hoping a whiff of wind doesn't blow you off boresight!

Getting Our Bearings

To locate a satellite, we must use some frame of reference or coordinate system. While astronomers use the galactic, ecliptic, and equatorial systems, we can take the easy way and use the horizon-coordinate system because the satellites appear to us as static points in the sky. Horizon coordinates are simply azimuth and elevation. Think of elevation as being so many vertical degrees up from your horizon and think of azimuth as a horizontal twist around to the satellite from a point looking at true north. The vertical tilt and the horizontal twist are seen in Fig. 2. That's all there is to it.

Let's get some idea of what the belt looks like from your location. We also can find a good spot for the dish at the same time. Go outside and look at the southern sky (readers below the equator look north). If you are at a medium latitude, say 30 to 40 degrees north, imagine a giant rainbow arch sweeping across the southern sky from east to west with its highest point about 45 degrees off the horizon (see Fig. 3). Perhaps your imaginary rainbow passes through a tree or rooftop. If so, you'd better find another spot for your dish.

At this point it's a good idea to do some research, and either calculate, compute, or buy a computer printout of satellite coordinates for your specific location. Then go outside again and pinpoint the direction of each satellite you may want to receive before

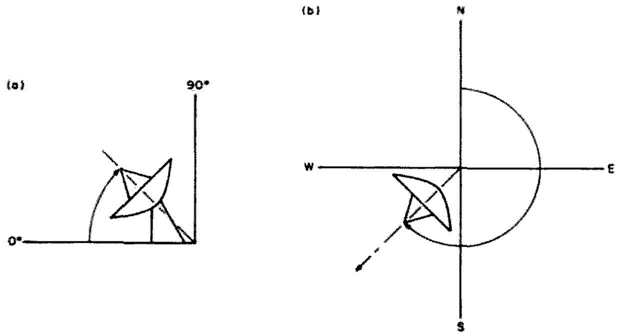

Fig. 2. Az/el coordinates are simple to understand. Elevation is a vertical tilt. Azimuth is a horizontal twist from true north (not magnetic north). (a) Elevation angle is measured from your horizon. (b) Azimuth angle is measured from true north turning clockwise.

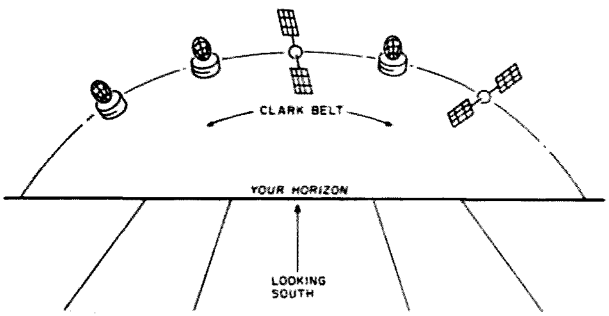

Fig. 3. To an observer at 30 to 40 degrees latitude, the Clarke belt appears as a giant rainbow. At the equator, the Clarke belt appears directly overhead stretching east and west.

Go Crazy Doing It Yourself

The following cookbook procedure is a summary of several articles on the subject which I've reduced down to three formulas. Even at that, you may find the process burdensome without a full-function programmable calculator. In the unlikely event that you are reduced to the bare essentials of just a cheapy pocket job or, God forbid, a book of trig tables, here are the exact steps to take:

1) Find out if the satellite is visible from your location and skip this step if you're pretty sure the bird can be seen. Otherwise, calculate the following (watching the signs!):

LD = Satellite Longitude − Your Longitude

Stop here if LD is greater than 81.3 degrees: You can't see it because it's below your horizon.

Then, where LAT = your latitude (use a negative latitude if you are below the equator) and AD = the number of angular degrees you are from the satellite subpoint, do:

$AD = \cos^{-1}(\cos LD \cos LAT)$

AD must be *less* than 81.3 degrees or you should forget it.

2a) Calculate azimuth if you are in the *northern* hemisphere, where LAT = your latitude:

$AZ = 180 + \tan^{-1}(\tan LD/\sin LAT)$

2b) Calculate azimuth if you are in the *southern* hemisphere by using a negative sign in front of latitude, where LAT = −(your latitude):

$AZ = \tan^{-1}(\tan LD/\sin LAT)$

3) Calculate elevation angle:

$EL = \tan^{-1}(\cos LD \cos LAT - .151/\sqrt{1-(\cos LD \cos LAT)^2}$

You can read more about bird hunting and even dig into the math in the following references:

"Microcomputers and the Satellite Station," Taggart, *73*, February, 1980.

"Locating Geosynchronous Satellites," Johnston, *QST*, March, 1978.

"Calculating Antenna Bearings," Shuch, *Ham Radio*, May, 1978.

Satellite Navigator Manual, Gibson, published by STTI.

you start pouring a concrete antenna base. A friend of mine skipped this step and accidentally erected his dish so that the best TV satellite worth viewing was directly behind a tree!

Even a clear shot doesn't mean you won't have problems, however. I recently moved to a mountaintop where nothing would block my view. Nothing, that is, except heavy interference from Ma Bell who just happens to share this same frequency band (3.7-4.2 GHz)! Ma Bell is a different kind of blockage. I'll cover the illness and the cure for interference in a future "Satellite Central."

Finding All the Info

Scores of articles (and even books) have been published on how to calculate satellite bearings. I've assembled a bibliography of a select few in the box on this page so that you can go hunting for back issues. Or you can scan the pages of *73* for someone who'll generate a bearing chart for you by computer. If you own a computer or know somebody who'll lend you one, you can use the program listing given here. It's nothing fancy, but it will give you answers with even greater accuracy than you need to point your dish.

It doesn't matter if you opt for graphs or calculators or even a computer to do the work. You still need three pieces of information before you begin: (1) The longitude of the desired satellite, (2) your longitude, and (3) your latitude.

Perhaps you're wondering why we need only the longitude of the satellite? Another look at Fig. 1 will show you that despite their distance, the latitude of the birds is really zero because they orbit directly above the equator. That's zero degrees latitude. So all we need is longitude. This is measured in degrees running east or west from Greenwich, England. If you look at the program listing, you'll see the west longitude of nearly all Clarke-belt satellites down in the data statements.

Next, you'll need your site coordinates. Like the satellites, your location is measured from the same references, Greenwich, England, and the equator. A good place to look for your coordinates is on a topographical map. You can buy one for your area from a map store or direct from the Department of the Interior. Aeronautical maps are another good source. Even an atlas will do.

If you can't find a map, call a local radio or TV station and use their coordinates. Perhaps the coordinates of the club repeater will do if it's not too far away. Your local airport tower may be able to give you their coordinates. As a last resort, look in books dealing with astrology! You may find coordinates for your city or one nearby because astrologers also need coordinates to construct their charts.

Hair-Splitting Accuracy

Despite what the purists may say, practical experience has proven that you can be 15 or 30 miles off in coordinates and still find the bird! It's really all a matter of accuracy in

Program listing.

pointing your dish. The typical readouts you might use, such as a carpenter's inclinometer or a compass, may get you within a couple of degrees, anyway. It's like trying to read fractions of mph on your auto speedometer! That's why accuracy in calculations to several places is unnecessary. We'll attempt to solve this problem later on with a digital or analog readout.

There is a limit to the number of satellites that you can see from your location. The curvature of the Earth blocks your view. The limit of your visibility is about 81 angular degrees in any direction. And, because the satellites are located above the equator, you will see fewer birds as you move north or south. If your antenna were located on the equator, you could look ± 81 degrees along the Clarke belt and see a maximum number of birds. It's a great location except that very few birds lay footprints on the equator. See "Satellite Central, part I" (*73* for November) about footprints. So, you've got to move towards the footprints to receive pictures.

As you move farther away from the equator, the birds on the ends of the belt begin to drop below your horizon. At a point roughly 81 degrees north (or south), all the satellites drop from your view. What? No satellite TV at the north pole? At Thule, Greenland, for example, SATCOM II is just about 1 degree off the horizon. The Armed Forces Network uses a massive dish pointed at the horizon to receive transponder 9.

Signal level is not their only problem. At nearly zero degrees elevation, the dish intercepts terrestrial noise from the Earth which greatly increases their noise floor.

Save Time With a Computer

Perhaps the best way to get satellite bearings is with a computer. It's fast, accurate, and eliminates any drudgery other than merely typing the program into the machine. The listing given with this article is short and devoid of any fancy formatting because I have no idea which machine you'll be using. It's in Microsoft BASIC. Take it from there.

In a nutshell, the program asks for your coordinates and then calculates azimuth and elevation for each satellite in its 54-satellite data base. You can add new birds to the data statements as they are put into orbit. Just be sure to adjust the size of the FOR/NEXT loop on line 260 to accommodate them.

Buried in the code, down in line 400, is the calculation for what is known as slant-range. It is the distance to the satellite from your location and not much use to you unless you want to calculate signal level and happen to have an intensity-matrix overlay somewhere else. You still may want to include it in the printout. Just print the variable S in line 440. Then add ,"DISTANCE" onto the end of line 160 so you will have a title for the distance column (don't forget the comma). You also will find that C1 in line 360 is the distance to the satellite subpoint, a spot on the globe directly below the bird. You may want to print it, too.

The formulas don't work for the special case of an Earth station exactly on the equator. Everything works fine if you move the dish a short distance north or south. I've inserted a minor fudge factor of a few seconds of latitude in line 210 just in case you want to test your suspicions and see that a dish at that spot would indeed have an azimuth bearing of 90 degrees or 270 degrees. While fudge factors are not a very good idea, especially in a computer program, it sure beats getting a "division by zero" error message. Besides, the output still will be accurate to within 7.2 seconds of arc! It's hardly worth mentioning when you consider the *real* effort will be erecting that 10-to-20-meter dish on the equator to receive what few signals are actually available!

Other mods worth considering are an error trap so that only visible satellites are printed. You may also want a software counter so that the ouput doesn't scroll off the screen until the program receives a keyboard command. If you

have a printer, it's a simple matter to change all the PRINT statements to LPRINT. Or you could store the answers in another array, then branch to a printer subroutine. TRS-80 Model I users need only POKE the printer device control block with the CRT vectors and LPRINT thereby, having their cake and eating it with optional branches.

Satellite Central needs your input of comments and ideas—with full credit to be given, of course. Most of the new developments in just the last two years have been from hams like yourself who have adopted a "Gee whiz, why can't we do it this way?" attitude, and have developed extraordinary designs that "won't work" according to the old guard. Yet simple things like $75 receivers and cheap window-screen antennas are appearing everywhere. The time is right for you to join in the fun of receiving TV from space.

If you have a question regarding the topics we cover here, feel free to drop me a line (letters only, no calls, please). Sorry, I can answer mail only when it is accompanied by an SASE. ■

Micro-Programmed Controllers

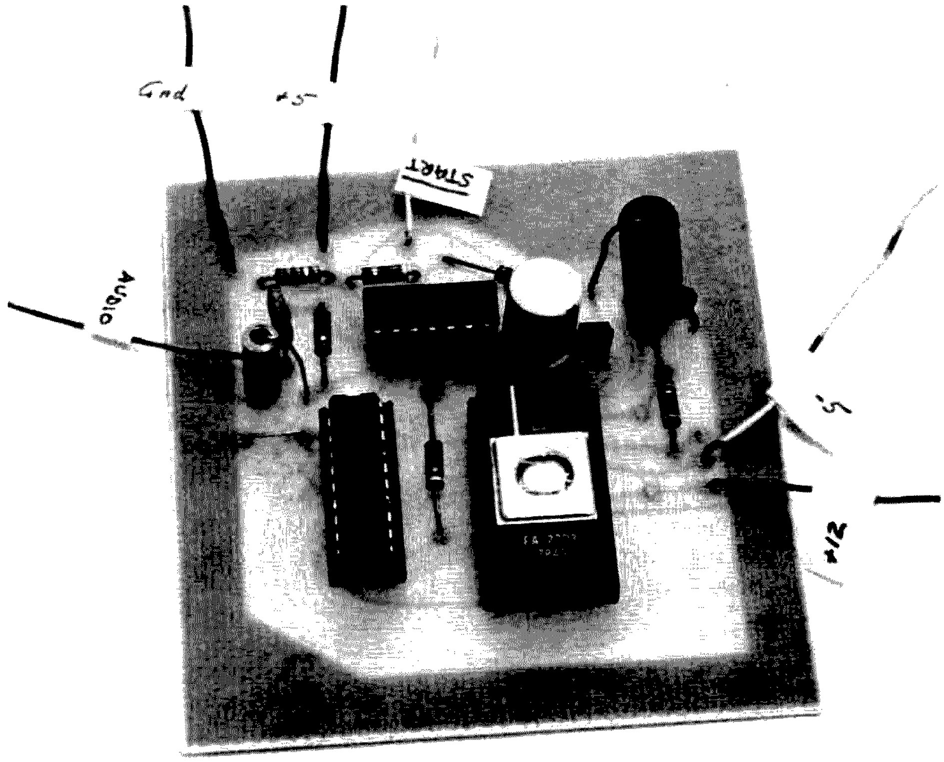
—bridging the gap between TTL and microprocessors

There are many times when you need some sort of digital circuit which gets its inputs from somewhere else, makes some simple decisions based on those inputs, and then feeds its outputs to still elsewhere.

A good example is a repeater control circuit. This device gets some inputs—usually digital signals which signal some on/off condition with either 0 volts or +5 volts—from other parts of the repeater such as a timer, input carrier detector, or touchtone™ decoder. The control circuitry monitors these inputs, and when certain conditions are satisfied, it sends out control signals to other parts of the repeater such as the transmitter keying relay or an autopatch.

Obviously, such a device is called a controller because it controls things. Although I'm using a repeater control circuit as an example, in reality controllers are much more useful. A controller can be used to control a complex RTTY station, a home heating system, or a burglar alarm.

Controllers used by hams typically take one of three forms. In the simplest cases, a controller may be built out of relays. In somewhat more complex systems, a controller might be built out of digital logic devices such as the 7400-series TTL integrated circuits which are used in most ham repeaters. And a few repeaters have controllers that use a microcomputer. Obviously, the more complex a controller, the more sophisticated control it can provide. And the computerized repeater systems have some really impressive features.



Relay controllers and controllers built out of just digital logic often are called hard-wired controllers. Their functions are wired into the system. Changing the way the controller works or fixing a bug requires that the wiring be changed.

Computerized controllers, on the other hand, are programmed controllers. Their functions are coded into a computer program which controls the computer. To change what the controller does or to fix a bug, you leave the wiring alone but change the program. This makes modification of the system a snap.

For some simple applications, however, programming a digital microcomputer can be overkill. For these cases, it would be

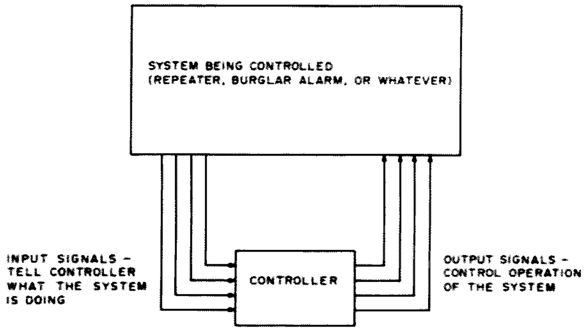


Fig. 1. How a controller fits into a system.

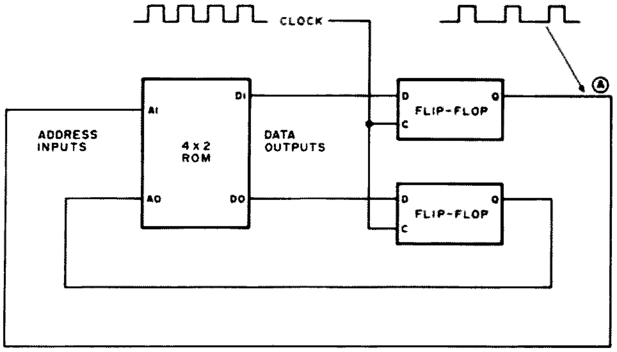

Fig. 2. A very simple micro-programmed sequential circuit.

nice to have a simpler device which uses some hard wiring but which can also be programmed to allow simple modifications or improvements as time goes on. Such a device is the micro-programmed controller.

A micro-programmed controller has a program which controls its operation but doesn't have a computer to go with it. Hence, it is much simpler to understand, build, and use. It doesn't have the full power of a computerized controller, but for most simple control jobs, it is good enough.

Micro-programmed controllers are nothing new; in fact, many computers have one inside them for control of their own internal operations. They are seldom used on their own, however, primarily because they are not well known. The purpose of this article is to introduce this very useful and powerful device to hams.

Sequential Controllers

Fig. 1 shows a simple block diagram of how a controller fits into a system. There are inputs from the system to the controller which tell the controller what is going on in the system. In a repeater, for instance, these might come from the carrier-operated relay (COR) or from tone decoders; in a burglar alarm, these might come from door and window switches.

In turn, the controller sends back some output signals which do things in the system. In a repeater, these might turn on the transmitter or autopatch; in a burglar alarm, they might ring an alarm bell.

Depending upon what the controller does, there are two types of controllers—combinatorial and sequential controllers. Both types have some inputs and provide some outputs. In a combinatorial controller, those outputs depend upon only the present inputs. In a sequential controller, the present outputs depend not just on the present inputs but also on past inputs.

Another way to look at this is as follows: For a particular combination of inputs, a combinatorial controller will always do the same thing, but a sequential controller has memory and will do different things if input signals arrive in a different order.

Consider the example of a burglar-alarm controller. In a combinatorial controller, every time the front door opens, the alarm bell rings. If there is a screen door just outside the main door, then the combinatorial controller will ring the bell when the main door opens even if the screen door is closed. But this would ring the bell when you leave the house.

On the other hand, a sequential controller could be connected to both doors. It could be set up so that if the screen door opens first and then the main door opens, the bell rings. But if the main door opens before the screen door, then the alarm does not sound. This controller would allow someone to go out but not in. In other words, the sequence of inputs is important.

A sequential controller also can provide a sequence of outputs. It could pulse the alarm bell on and off, or turn it off after ten minutes, or it could alternately pulse a bell and a siren, or toot a song on several horns of different pitch. A combinatorial controller can't do that.

Obviously, a sequential controller is more useful and interesting. It's also more difficult to build. A combinatorial controller can be just a series of relay contacts or simple digital logic which provides an output when some particular combination of inputs is present. A sequential controller, on the other hand, has to have some built-in memory to remember what has happened in the past, and often must have some delay circuits or timers as well. This is why complex ham controllers often have complicated digital logic circuits or microcomputers.

Micro-Programmed Sequential Controllers

A lot of people think that programming a microcomputer is called micro-programming. Not so. Micro-programming means programming on a small scale. In this case, we program a simple circuit to do some very simple things.

Fig. 2 shows a very simple micro-programmed sequential circuit consisting of a read-only memory (ROM), two type-D flip-flops, and some sort of clock to generate pulses which go to the flip-flops. (This circuit is so simple that it doesn't have any inputs or outputs to the outside world. Hence, this sequential controller can't do anything useful—yet.)

The ROM is a digital memory. It is divided into a number of locations, each of which stores a binary number. In Fig. 2, this is a 4 × 2 ROM, meaning that it has four separate memory locations and each stores two binary digits.

(In case you are not familiar with digital logic, the binary digits (bits) are either 0 or 1. In most common digital circuitry, a 0 is carried along a wire as a voltage of 0 volts, or very close to it, while a 1 is represented by a voltage above 2 volts. Although we tend to think of 0 and 1 as being 0 volts and +5 volts, since these are the supply voltages used in TTL integrated circuits, the most common voltage for a 0 is about 0.2 volts, and the most common voltage for a 1 is between 3 and 4 volts.)

Each of the four locations has an address; this address also is a binary number. In this case, we need two bits to specify an address. The four different addresses are 00, 01, 10, and

11. (Only the digits 0 and 1 are allowed in binary numbers, and these are all the possible combinations that you can make out of a pair of bits.)

The ROM memory has a set of address inputs and a set of data outputs. When you feed in an address on the inputs, the ROM "looks up" the contents of the location you've addressed and feeds the contents of that location out over the data outputs. The 4×2 ROM shown in Fig. 2 has two address input lines (since it needs two bits to specify one of its four addresses) and also happens to have two data output lines, since each location only holds two bits. As such, this is a tiny ROM—so small that nobody makes it. A typical manufactured ROM might have 1024 memory locations with 8 bits in each location.

The ROM gets its data by being programmed. Some ROMs are programmed in the factory when manufactured; other ROMs can be programmed in the field. The particular ROMs hams use most often can not only be programmed in the field, but can also be erased; they are called EPROMs, for Erasable Programmable ROM.

Suppose we programmed the 4×2 ROM as follows:

Location (Address)	Contents (Data)
00	01
01	10
10	00
11	11

This shows exactly what is in it. Each of the four locations has a two-bit number. Let's remember this pattern as we go on.

In Fig. 2 is a pair of type-D flip-flops. A flip-flop is a digital logic device which has a memory. When you apply a bit to its D (data) input and put a pulse on its C (clock) pin, it will memorize that bit and keep sending it out the Q output for as long as power is applied or until the next data bit and clock pulse arrive.

In this case, the data arrives from the ROM and is supplied to two flip-flops, one for each bit. The clock signal is a series of pulses generated by some sort of oscillator which arrive at regular intervals. Every time a clock pulse arrives, the two flip-flops memorize the binary data coming out of the ROM and then feed the data back out their Q outputs. This output will then stay there until the next clock pulse arrives, at which time it may change.

Now, we notice that these Q outputs go right back to the address inputs of the ROM—so this is some sort of feedback circuit. If you are at all familiar with feedback, you will remember that feedback does strange things . . . like make amplifiers oscillate. That's exactly what can happen in this case; it can make the ROM oscillate. But the flip-flops can be thought of as a delay. When an output comes from the ROM, it doesn't enter the flip-flops until the next clock pulse. If the clock pulses are arriving very slowly, then there may be a long delay from the time the output of the ROM comes to the time it finally reaches the address inputs. The ROM can oscillate only as fast as the clock pulses arrive.

Now let's go back to the pattern we programmed into the ROM earlier, and let's assume that we somehow start with the flip-flops putting out a digital signal of 00. This 00 is sent back to the ROM as an address. Since the ROM has been programmed with a 01 at location 00, it will feed a data output of 01 to the two flip-flops.

At some time later, a clock pulse arrives. All of a sudden, the flip-flops get triggered and memorize the 01 pattern. Now they output 01 back to the ROM's address inputs.

The ROM now gets an address of 01, and so it outputs 10 as data. This goes to the flip-flops, but again nothing happens until a clock pulse arrives. When it does, suddenly the 01 on the flip-flop outputs changes to 10. This goes back to the ROM's address inputs so that the ROM now outputs 00, the number we programmed into location 10. But again, nothing happens until the clock pulse comes. When it finally arrives, the 00 will appear on the flip-flop outputs, and we're right back where we started.

If you leave the circuit sitting there for a long time, it will simply keep cycling back and forth: 00, 01, 10, 00, 01, 10, 00 . . . and so on. It goes through a sequence of addresses. If we call each different address a state, we see that the number going into the ROM is the "present state" while the number coming out will be the "next state." We could rewrite the ROM memory table like this:

Present State	Next State
00	01
01	10
10	00
11	11

Once we're in present state 00 (in the left column), we will go to state 01 (right column) when the clock comes. When we're in state 01 (left column), the next state after a clock comes will be 10 (right column). Finally, from a present state of 10 we'll go right back to 00.

While the circuit is going back and forth like this, we could connect an oscilloscope to point A (see Fig. 2) and would see the waveform shown, since this line is a 0 for two clock pulses and a 1 for one clock pulse. This circuit could, therefore, take a symmetrical clock pulse and produce an output which is unsymmetrical. You can see that, given enough states, we could make this waveform as complex as we'd like. (Later, I'll show you how to build a CW identifier using just three integrated circuits.)

Suppose, though, that somehow we had started off with the flip-flop outputs equal to 11. This table shows us that location 11 has the data 11, so the next state also will be 11. In this case, the circuit will just lock up and stay in the 11 state forever.

So, we have here a circuit which will go through a succession of states following exactly the pattern which is programmed into the ROM. But we have to be careful not to mix up the bits being fed back or the sequence of states will not be the right one. We do this by noting which of the address inputs is the left digit and which is the right. In Fig. 2, we see that the address inputs of the ROM are labeled A1 and A0. When we write

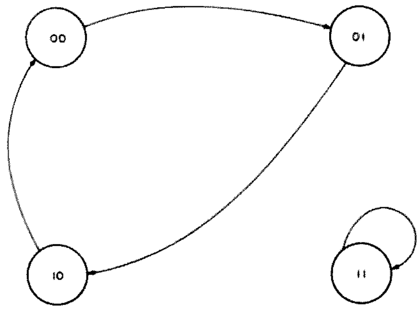

Fig. 3. State map for the circuit in Fig. 2.

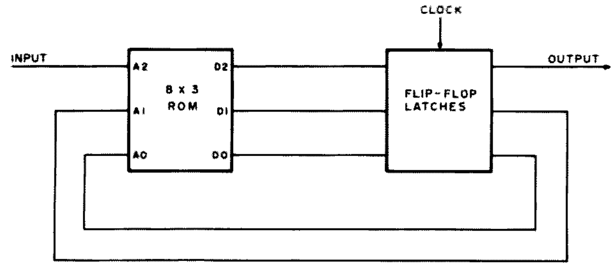

Fig. 4. A more complex controller.

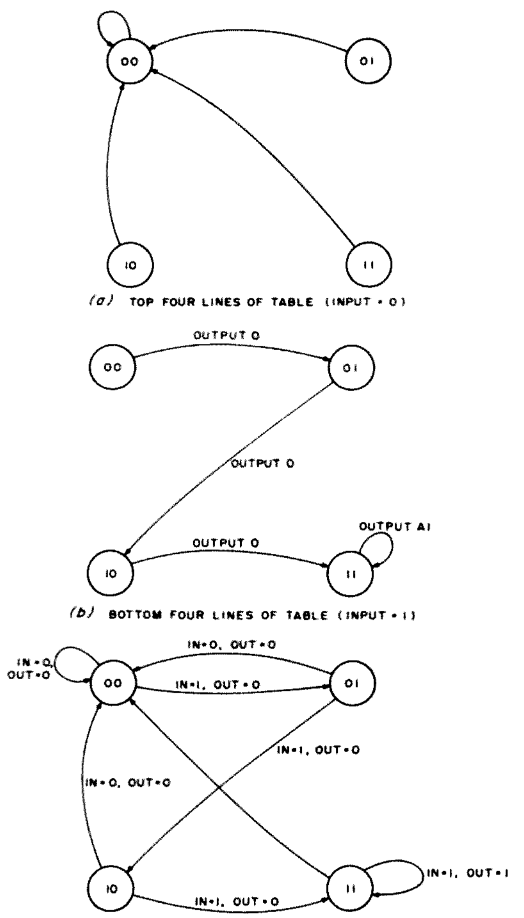

(a) TOP FOUR LINES OF TABLE (INPUT = 0)

(b) BOTTOM FOUR LINES OF TABLE (INPUT = 1)

(c) COMBINATION OF (a) AND (b)

Fig. 5. State map for Fig. 4.

these two bits down on paper, A0 is at the right and the bits are numbered higher as we go left. (For instance, a ROM having ten address inputs would have them numbered from A0 on the right to A9 on the left.) In the same way, D0 is the data bit at the right, and we must make sure that D0 goes around in such a way that it comes back to A0, not to A1.

To make the operation of a circuit like this easier to understand, we use a "state map" or "state diagram," as in Fig. 3. In this map, each state is shown as a circle which is numbered with its state. Like one-way roads on a road map, arrows show how we go from state to state. From state 00 we go to 01, from 01 to 10, from 10 back to 00. But if we're in state 11, then the road leads right back to 11.

Let's look at the more complex circuit in Fig. 4. Since this ROM has three address inputs and three address outputs, it is an 8×3 ROM (there are eight possible ways we can write the three address bits and there are three bits per location). We now need three type-D flip-flops, but rather than showing them individually, we just show them as a big box. Since these flip-flops grab an input and hold it until the next clock pulse, they are usually called latches.

This time we don't feed all the outputs back to the input. We reserve one of the address lines as an input from somewhere else and use one of the latch outputs for an output to somewhere else. Only two lines are fed back. (The fact that this ROM has the same number of address inputs as data outputs is just coincidental. Most modern ROMs have more address pins than data pins. For instance, the EPROM in Fig. 9 has ten address inputs and only eight data outputs. Sometimes all the outputs go back to the inputs and other times only a few lines go back. It all depends on the application.)

Now, let's assume that this 8×3 ROM is programmed as follows:

Location (Address)	Contents (Data)
000	000
001	000
010	000
011	000
100	001
101	010
110	011
111	111

Notice in Fig. 4 that the two bits on the right of each set are being fed back through the latches; let's call these two bits "the state." The remaining address bit will be the input bit, and the remaining data bit will be the output bit. Then we can rewrite the table. The first column will look like this:

Input	Present State
0	00
0	01
0	10
0	11
1	00
1	01
1	10
1	11

and the second column will look like this:

Output	Next State
0	00
0	00
0	00
0	00
0	01
0	10
0	11
1	11

What does this table tell us? The top four lines of each say this: As long as the input is 0, regardless of what state we're in, the output will be a zero and we will go to state 00 next. This means that when the input is a 0 for a long time, the circuit simply locks up in state 00 and keeps providing a 0 output all the time. The state map for these four lines is shown in (a) in Fig. 5.

Now, suppose that we're in state 0 for a while and suddenly the input changes from 0 to a 1. All of a sudden we're on line 5 of the input table—input 1, present state 00. Then, after the next clock pulse (let's repeat that again—*after* the next clock pulse), the output will stay at 0 but we will go to state 01 (down to line 6 of the input table).

The state map for the last four lines of the input table is shown in (b) in Fig. 5 and shows how we move from state 00 to state 01 if the input is a 1.

If the input should go back to 0, we'd move back to line 1, and at the next clock pulse, we'll simply shoot back up to state 00 again. But let's assume the input stays at 1 for a while. Then, at the next clock pulse, we'll move to state 10. When we're in state 10 with the input still 1, the next clock pulse moves us to an output of 0 and state 11.

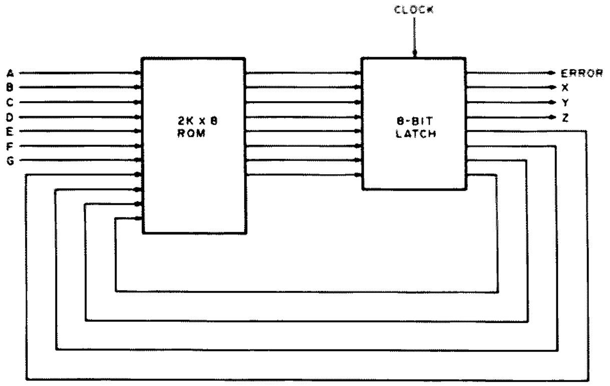

Fig. 6. Digit-sequence detector for touchtone.

At this point, we're in state 11 with an input of 1. At the next clock pulse, we stay in state 11, but the output goes to 1. If the input now stays at 1, we will stay in state 11 for a long time. We can see this clearly from the state map in (b).

But when the input finally goes back to a 0, which brings us back to the state map in (a), we will switch suddenly to line 4—input of 0 and present state 11. That means that the next clock pulse will bring us back to state 00 with an output of 0.

So, this is a delay circuit of sorts. If the input is 0 for a long time, the output stays 0. When the input goes to 1, the output stays at 0 until four clock pulses later, at which point it finally goes to 1, too. But if the input goes to 0, then the output drops back to 0 at the very next clock pulse. A circuit like this might be usable in some sort of alarm, for instance.

Although we broke up the state map into two parts, (a) for the case when the input is 0 and (b) for the case of a 1 input, we usually combine both parts, as in (c) in Fig. 5, and carefully label all combinations of input and output.

Although the function of this controller could just as well be done with a simpler circuit, the point here is that just by reprogramming the ROM we can get the same circuit to do something completely different. For instance, we could change the last two lines of the table as follows:

(Column 1)		(Column 2)	
1	10	1	11
1	11	0	10

The circuit here would oscillate between states 11 and 10 and would pulse the output on and off. This could pulse an alarm bell a certain time after a door opened for instance.

Now we see why this is called a micro-programmed sequential controller. It is programmed via very simple (micro) instructions, it operates in a certain sequence, and it can be used to control things.

This idea is a very powerful one. For instance, if we had a ROM with ten address inputs and eight data outputs, we could feed back, say, four data lines to become addresses. Using these four lines to mark our states, we get a total of sixteen states (there are 2-to-the-4th or 16 possible ways of arranging four 0s and 1s). That leaves six address lines to be used for inputs to the circuit and four data lines for output. A circuit like this could be used as a fairly neat traffic-light controller. The six inputs might go to traffic sensors and a timer, while the four outputs would control a pair of red and green lights. The circuit could then switch the lights in a prearranged sequence, depending on the external timer inputs and the presence of traffic.

Just two more concepts before we look at another practical example.

The number of memory locations depends on the number of address lines, because these determine how many different addresses we can make. With two lines, we could have only four different addresses (00, 01, 10, and 11). With three address lines, we could have eight addresses; with four lines we could have 16 addresses. The equation to use is: Number of locations $= 2^n$, where n is the number of lines. For instance, the ROM with ten address lines has 1024 memory locations, since $1024 = 2^{10}$.

In electronics, a k means 1000. In digital computer talk, K means 1024, so the above ROM would be called a 1K memory. If you examine Fig. 9 carefully, you will see that that circuit uses a 1K×8 ROM, since there are 10 address lines and 8 data lines.

The other thing to keep in mind is that binary numbers are easy to use if they are small. But talking about big binary numbers like 10011110 gets confusing. Hence, most computer people use a different number system. Either octal or hexadecimal (hex) is used, but hexadecimal is currently more popular. In hex, a binary number is divided into groups of four bits, and each group is then replaced by its corresponding hex digit. As shown in Table 1, hex uses the digits 0 through 9 and the letters A through F. Since 1001 is 9 and 1110 is E (see Table 1), the binary number 10011110 would be written as 9E in hex.

This is easy to do when the binary number has 4, 8, 12, or 16 bits. But when it has 9 or 10 bits, how do you split them into groups of four? The secret is to add zeros in front of it to stretch it out to a multiple of four bits. For instance, the binary number 110011110 would be stretched out to 000110011110, split up into 0001-1001-1110, and then written as 19E in hex.

Decimal Number	Binary Number	Hex Number
0	0000	0
1	0001	1
2	0010	2
3	0011	3
4	0100	4
5	0101	5
6	0110	6
7	0111	7
8	1000	8
9	1001	9
10	1010	A
11	1011	B
12	1100	C
13	1101	D
14	1110	E
15	1111	F

Table 1. Binary and hex numbers.

A Micro-Programmed Tone Decoder

Many repeater control circuits use touchtone™ signals (a dual-tone signaling system) for repeater control. The actual tones are detected by either tuned-circuit filters or 567 phase-locked loop ICs, and the detected outputs are then used to control repeater functions. Detecting the tones and providing an output for each tone is fairly simple; detecting a sequence of digits (such as dialing the number 1234) and providing an output only when these digits are dialed in the right order is a bit more tricky. A variety of circuits have been used, but a micro-programmed sequential controller can do the job just as well and with less hardware. (Just three ICs, in fact!)

Fig. 6 shows a simplified diagram of the scheme. If we use a 2K×8 ROM (which has 2048 memory locations and, therefore, 11 address-line inputs and 8 data-line outputs), we need an 8-bit latch. Feeding back four data lines from the latch leaves seven input lines and four output lines.

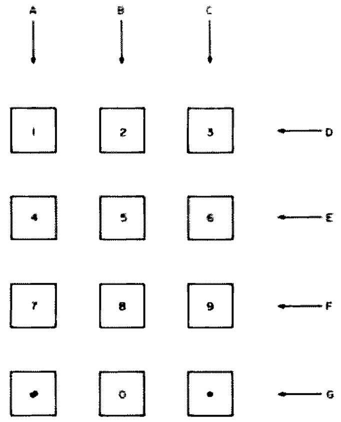

Fig. 7. A typical touchtone dial.

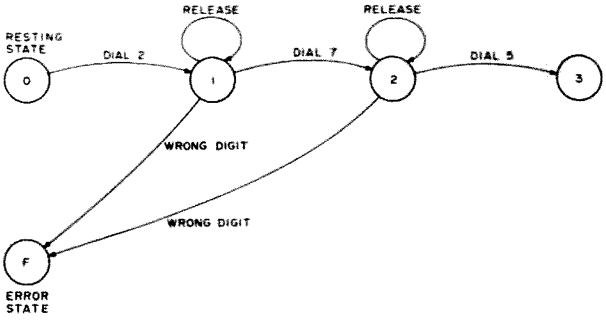

Fig. 8. Partial state map for touchtone-sequence detector.

Let's connect the seven inputs to seven outputs from the touchtone decoder. (There are seven tones used, so we would have seven tone decoders with each one providing one output to the ROM.) To keep things simple, let's call these inputs A through G.

On a touchtone dial, each digit generates a combination of two tones, depending upon the row and column position of that digit on the keyboard. All the keys in the left column of the touchtone keyboard, for example, generate two tones, one of which is 1209 Hz. Call the output of the 1209-Hz decoder A. In the same way, all the keys in the center column would generate the B signal, and so on, as shown in Fig. 7. For any particular digit, then, two input signals are generated; the digit 5, for instance, becomes the BE combination.

Of the four outputs, let's call one the ERROR output; we will set up the system so that if an error is made in dialing or if someone is playing with the system, we get a signal on this lead. The other three outputs are called X, Y, and Z and decode three separate dialed sequences of digits.

Now, let's suppose that we want output X to go on whenever the repeater user dials the sequence *275. Fig. 7 shows that the * is a CG combination, a 2 is the BD combination, the 7 is the AF combination, and the 5 is the BE combination. So, we want our sequential controller to provide an X output when the input sequence detected is as shown in Table 2.

Between digits, however, both tones will disappear (though perhaps not at the same time). Now, how do we figure out how to program the ROM?

The solution is to start with a state map. Since there are four feedback lines, we can have up to sixteen states (since 2 to the 4th power is 16). Let's number them in hexadecimal as states 0 through F (since Table 1 tells us that a hex F is the same as a decimal 15).

With sixteen states, the state map is quite complex, so let's just show five states in Fig. 8. Let's label state 0 the "resting state" and state F the ERROR state. States 1 through 3 are then used for the *275 sequence, while states 4 through E (not shown) would be available for other number sequences.

We'll set up the program so that the controller is normally in the resting state; if it's anywhere else, dialing a * will send it there (that's the purpose of starting the *275 sequence with a *). Hence, state 0 is always the starting point for any number.

Once we're in state 0, dialing a 2 takes the controller to state 1, where it stays as long as the 2 is dialed and also when the digit 2 is released. When the 7 is dialed, the controller moves to state 2 and stays there. Finally, when the 5 is dialed, it goes to state 3. If at any time the wrong digit is dialed, the system goes to state F.

Notice that there is a tremendous amount of flexibility here. Depending on exactly how we program the ROM, we can ignore wrong digits while we're in state 0 or go to the ERROR state. We can stay in state 3 after the *275 is dialed until the next * takes us back to state 0, or we can set it up so that the system returns to 0 on the very next clock pulse. Or, we can set up another dialed number sequence to return to state 0.

We can stay in the ERROR state on an error and lock up the whole system, or we can return to 0 on the very next clock pulse. Or, we can stay in state F until a special dialed sequence returns us to state 0; this would allow only control stations to reset the system. The possibilities are immense, with the only limitation being the size of the ROM. This circuit has fourteen available states (since two are used up for the resting state and the ERROR state); since each digit requires one state, we can handle up to fourteen digits (not counting the * code). We could, therefore, decode a 14-digit number, or two 7-digit numbers, or three 3-digit numbers and one 5-digit number, or any combination we please.

Now, what about the actual ROM program? This is where the job gets slightly tedious (but not at all difficult). Since a 2K × 8 ROM is used, we have to figure out exactly what to put in each and every one of those 2048 locations. We cannot leave any location empty for a very important reason—when power is first turned on, the state of the system is unpredictable. If it should go into some state for which we did not plan, the controller could lock up in that state and never come out of it. Hence, any ROM location we don't specifically need should be programmed with some "escape" data which allows the controller to return to resting state 0.

The basic idea, therefore, is to start with a notebook and set up one line in the notebook for each of the

A	B	C	D	E	F	G	
0	0	1	0	0	0	1	(C & G tones = *)
0	1	0	1	0	0	0	(B & D tones = 2)
1	0	0	0	0	1	0	(A & F tones = 7)
0	1	0	0	1	0	0	(B & E tones = 5)

Table 2.

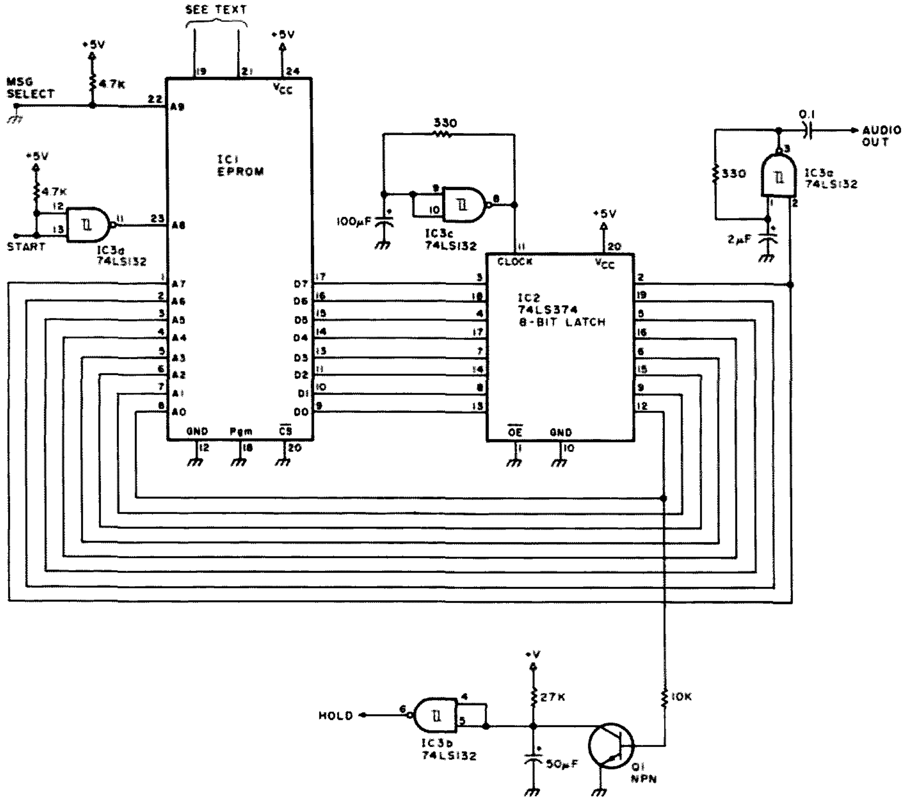

Fig. 9. CW identifier diagram. 74LS132 ground is pin 7; Vcc is pin 14.

	Inputs A B C D E F G	Present State	Outputs ERROR	X Y Z	Next State
a)	(eleven-bit address)		(eight-bit data)		
		First line:			
	0 1 0 1 0 0 0	0000 (0)	0	0 0 0	0001 (1)

	Inputs A B C D E F G	Present State	Outputs ERROR	X Y Z	Next State
e)	1 1 0 0 0 0 0	0001 (1)	1	0 0 0	1111 (F)
	1 0 1 0 0 0 0	0001 (1)	1	0 0 0	1111 (F)
	1 0 0 1 0 0 0	0001 (1)	1	0 0 0	1111 (F)
	1 0 0 0 1 0 0	0001 (1)	1	0 0 0	1111 (F)
	etc.				

Table 4.

2048 different addresses, in order. See Table 3.

Next, remember that every unused location should get the data 00000000, which will lead to state 0 (or binary 0000) with all outputs off. This is the escape code which leads back to state 0 if the system ever gets to some unused state. No need to put all those 00000000 codes in yet, but remember them at the end.

Now make yourself a template which will indicate which bit of the address and data is what. The template should look something like the top of Table 4(a). Here we have made a start in filling in the programming table. First, we want to go from state 0 to state 1 when a 2 is dialed, but keeping all outputs off. This is just the one line of Table 4(a).

This entry says that when we are in state 0 and the BD pair of inputs comes in, we

00000000000 = hex 000
00000000001 = hex 001
00000000010 = hex 002
00000000011 = hex 003
•
•
•
11111111111 = hex 7FF

Table 3.

want to make the four outputs all 0 and also go to state 1. (The state numbers are shown in binary and the hex state number is in parentheses.)

Once we get to state 1, we want to stay in that state under three possible conditions:

1) as long as the digit 2 is still present;

2) when the digit 2 has disappeared (B and D are both gone); and

3) whenever only one tone is present. This is not shown in the state map, but is due to the fact that when one digit is dialed, the two tones it represents do not come on and off together but may follow each other with a small time delay. Furthermore, some tone decoders may output short pulses if they are triggered by noise or voice signals. Hence, we want to ignore any input which represents just one tone.

These three conditions translate into nine memory locations to be programmed as in Table 4(b).

The first line keeps us in state 1 when the BD combination (digit 2) is on; the second line keeps us in state 1 when all tones are absent; the last seven lines keep us there if just one tone is detected.

Next, we want to program in the sequence which returns to state 0 when a * is dialed. This is again just one line as in Table 4(c).

When the digit 7 is dialed, we want to go to state 2—see Table 4(d).

Finally, for every other combination of tones, we want to go to the ERROR state F—see Table 4(e).

To give the complete

micro-program for the ROM would take a few pages; besides, the exact program depends on just what options you want to include in the system. For example, the state map in Fig. 7 would ignore multiple digits (*275 would be treated the same as *2275 or *2227777775). In a repeater system where mobile flutter often breaks up one digit into two, this might be preferable, but if this were not acceptable, then breaking up each state into two states (for example, staying in state 1 as long as the 2 is still present, but going to another state as soon as it is released) would eliminate that. In any case, the program would change for every application, so there isn't much need to give one here. But you'd find that it isn't very difficult once you get started.

As to the actual circuit, something similar to Fig. 9 using a 2716 2K × 8 EPROM, a 74LS374 eight-bit latch, and a 74LS132 for buffering and clock would work out just fine. At what frequency should the clock run? The frequency should be fast enough so that a digit is not missed between two clock pulses, but slow enough so that short noise bursts which may produce tiny pulses at the outputs of the tone decoders don't confuse the system. A frequency of perhaps five pulses per second should be about right, but there is nothing critical about this value.

A Micro-Programmed CW Identifier

Here is a practical application of a micro-programmed sequential controller that a lot of hams can use—a CW identifier which has only three integrated circuits.

Fig. 9 shows the complete circuit. It consists of a 1K × 8 EPROM (in this case a 2708, but others can be used), a 74LS374 8-bit latch which contains eight type-D flip-flops, a 74LS132 quad, a 2-input Schmitt trigger, a transistor, and a handful of resistors and capacitors.

IC1 is the EPROM, hooked up to IC2 in a straightforward micro-programmed sequential controller circuit. There are eight bits brought back as feedback, which leaves two more EPROM address lines as inputs. A8 (pin 23) is buffered through IC3d and acts as the START line. The 4.7k resistor on the input normally keeps the START line at a high voltage near +5 volts, and grounding it starts the IDer.

The other input pin, A9 on pin 22, is used as a message select. In my circuit, I simply keep it grounded all the time as I don't have a second message in the ROM, but if it is allowed to go to a high voltage (with the 4.7k resistor pulling it up), this selects the other half of the ROM and allows a second call to be stored. Each call or short message requires 512 locations (½K) of storage, so the 1K EPROM has room for two messages.

Two sections of the 74LS132 act as oscillators. Up at the top, IC3c oscillates at a frequency of about 20 Hz and, therefore, clocks the latches twenty times per second. This determines the speed at which the circuit goes from one state to another and is the duration of a Morse code dot.

IC3a also oscillates, but at the much higher frequency of about 1000 Hz, and generates the CW-tone output. It is keyed on and off by latched D7 output coming from IC2, pin 2.

In many cases we need a HOLD signal which keys a transmitter whenever the IDer is active. This is done by the circuitry around IC3b. Normally, the capacitor connected to its input charges up to near +5 volts through the 27k resistor. This makes the input into IC3b high (1), so its output is a low voltage (0).

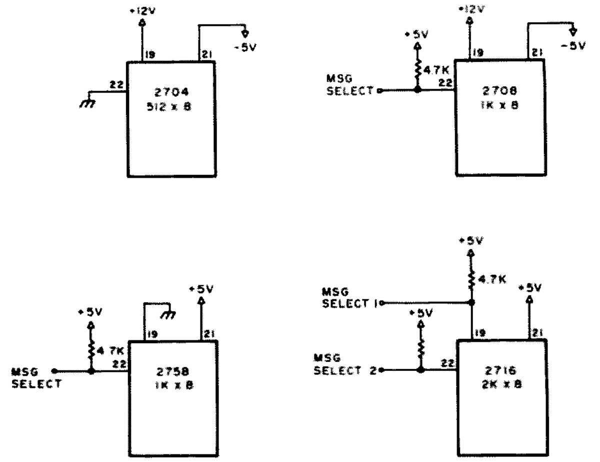

Fig. 10. Four different EPROMs can be used.

Each time the latched data bit D0 goes to a 1, however, the transistor turns on and discharges the capacitor. This makes the HOLD output go high to a 1.

When the IDer is sitting still, D0 is always a 0, and so the HOLD is always low. But as soon as it starts, D0 alternates between 0 and 1, and so the capacitor keeps being discharged all the time. Hence, HOLD goes high and stays there until a half second or so after the IDer stops.

IC1 as shown in Fig. 9 is a 2708 EPROM, available for about $6. But the 2708 has a disadvantage—it requires three power supplies of +5 volts, −5 volts, and +12 volts, respectively. This makes it hard to use. But it's possible to substitute other EPROMs. Fig. 10 shows how to change the EPROM connections for three other EPROMs; only pins 19, 21, and 22 are affected. Like the 2708, the 2704 also requires three power supplies but has only 512 locations (½K) storage. This EPROM could store only one call, and, so, pin 22 is grounded rather than being used as a message select pin. It is not easy to get since everybody has switched to the 2708 at almost the same price, but there may be some still lying around.

The 2758 and the 2716 require only a single +5-volt power supply. They are almost identical, except that the 2758 is 1K × 8, while the 2716 is 2K × 8. Quoted prices at this time are about $10 to $15 for either. The 2716 has an additional address line (pin 19) which becomes a second message select line. Since this EPROM has 2K locations, it can store four different calls or short messages. They are selected by putting various combinations of ones and zeros on the two select lines; in the rest of this article, we'll just discuss the simplest case where all message select lines are grounded.

Incidentally, when ordering a 2716, do not order the Texas Instruments TMS2716. This IC is also 2K × 8 but requires three supplies like the 2708. TI uses the number TMS2516 for the EPROM with a single supply; everyone else calls it a 2716.

Programming CW into the EPROM

Although I use a computer program to determine the bit pattern to be put into the EPROM, it's important to understand how this is done. Following RTTY terminology, a dot is called a "mark" while the space be-

MSG Select A9	Start Input A8	Present State A7-A0	Next State D7-D0
0 (Gnd)	0 (Don't)	00000000	00000000
0	1 (Start!)	00000000	00000001
(10-bit address)			(eight-bit data)

Table 5.

Table 7.

tween two dots is called a "space." A dash then becomes three marks with no space between them, a letter space is four spaces in a row, and so on. The letter K then becomes mark mark mark space mark space mark mark mark.

A complete call requires 512 (½K) locations, numbered from 000000000 to 111111111 in binary; in hex they are numbered from 000 to 1FF.

In the EPROM, location 000 is always programmed with a 00 (so that once the sequential controller gets to state 00 it will lock up in state 00 and stay there). Location 100 is always programmed with a 01 (so that the controller will go from that state to state 1). A short table of these locations and data is shown in Table 5.

This shows that if we're in present state 00000000 (or 00 in hex) and the START input (on A8, not way back at the input to inverter IC3d) is a 0, then the next state will be 00 again. But if we're in state 00 and the START is a 1, then the next state will be 00000001 (or 01 in hex). This is how we handle the problem of getting started.

So these two locations (hex 000 and hex 100) are different in that one stores a 00 while the other stores a 01. As for all the rest of the message memory, ROM locations 101 through 1FF are an exact carbon copy of locations 001 through 0FF. In other words, once we get out of state 00 into any other state, the voltage on the START input doesn't matter any more; regardless of whether the START is still a 1 or whether it has already gone back to a 0, the sequence will be the same.

Now, what's in the rest of the ROM? Let's assume that the call consists of just the letter K (to keep it simple). The ROM contents is then as shown in Table 6. All the rest of the ROM message area is 00. What does all this mean?

First of all, notice in Fig. 9 that the latched D7 bit (which is the data bit on the left when the number is written down on paper) also happens to be the Morse code output bit which goes to the code oscillator, IC3a. When this bit is a 1, we get a tone output; when this bit is 0, we don't get any sound. When is this bit a 1? Whenever we're in any state whose state number starts with a 1; in hex, this means whenever the state number starts with an 8 or any digit greater than 8. So the IDer generates a tone (mark) in states 80, 81, and up, but not in 00, 01, or any state up to 7F.

Table 6 shows exactly which state follows which other state, but we have to pick our way through it to follow the states. It's much easier if we rearrange the lines into the same order that the circuit goes through. Let's do it as shown in Table 7, using an arrow to show how the controller follows the states. For instance, 01 → 02 means that present state 01 will be followed by next state 02.

All the states starting with 0 are at the left and represent spaces (no tone); the states starting with an 8 are at the right and represent marks (tone). Look at the marks on the right: mark mark mark (space) mark (space) mark mark mark. There's your K!

What we have, then, is six states of space (no tone), three states of mark (the dah that starts the K), one space followed by one mark (the dit), a space, and another three marks (the second dah). At the end, we have a letter space which consists of five more spaces. (The reason for the six spaces at the start is to allow the transmitter some time to come on before the letter is sent.)

In this case, we used a total of 14 space locations (states 00 through 0D) and 7 mark locations (states 80 through 86) for a start delay, one letter, and a letter space at the end. But actually we shouldn't count the six spaces at the beginning since they are a special case, so the letter K used only 8 spaces and 7 marks. With a total message space of 128 spaces (00 through 7F in hex) and 128 marks (80 through FF), this leaves us room for a message of about 15 characters. Enough to spell out something like K2OAW NEW YORK.

Programming the EPROM

Obviously, the hardest part of building this IDer is programming the EPROM; this job involves two parts—first deciding what to put in which location, and then going through the mechanics of doing the actual programming.

Deciding what to put into the EPROM can be done by sitting down with a notebook and making a table something like Table 7. Simply go through, putting down the marks and spaces which correspond to each dit and dah as well as the

spaces at the beginning, between letters, and at the end.

If a computer of some kind is available, then the program listing given here can be used. This particular program was written in SWTP BASIC for a SWTP 6800 computer, but since it's written in BASIC it should run on other small computers without much modification.

The program has an array called C which contains the dit-dah code for each letter, number, and some characters. When it runs, it asks for the message you'd like to program, converts each character in the message to the Morse code by looking it up in the table, and then figures out the EPROM pattern. It does two things with the resulting data—it POKEs it into memory and prints it out. If you have an EPROM programmer on the computer, then the data POKEd into memory could be used to program the EPROM directly; if the programmer is separate, then the printed listing would be used.

This particular version POKEs the data starting at decimal location 45056 (see line 60 of the program) which happens to be equivalent to the hex address B000 in the computer; this happened to be convenient in my system, but would probably have to be changed for other systems.

The Morse code pattern in array C is stored as two bits for each dot or dash. If the Morse code character has a dit, then the two bits are 01; a dah becomes a 11.

The letters coming from the keyboard are in a code called ASCII. For instance, the code for the letter K is hex 4B. This is equivalent to a decimal 75, so the code for K is stored in the 75th location of C, which is C(75).

Since the code for a K is dah-dit-dah, it is stored as 110111 (or 11 01 11). This binary number translates to a decimal 55, and so the Morse code for a K is defined in line 350 as C(75) = 55. Each of the other letters, numbers, and symbols is stored in exactly the same way.

Once you know exactly what data must be stored in the ROM, you must actually store it; this is called programming the ROM and requires an EPROM programmer. Such programmers come in two types—manual and programmed. In a manual programmer, each bit pattern for every location is entered by hand via switches and then a button is pushed to program that location. A programmed unit stores the entire code to be "burned" into the EPROM in its own memory first, and then programs the EPROM with that data. Most EPROMs can be programmed with a manual unit, but obviously a programmed unit is much more convenient.

If you run my program on a computer, it may be convenient to use a programmer which attaches to the same computer to transfer the bit pattern straight from the read-write memory of the computer to the EPROM. In the case of the SWTP computer, SWTP makes a 2716 programmer which also will program 2758s; a modification in a *Kilobaud Microcomputing* article (February, 1979, page 82) allows this same unit to program the 2708 or 2704; this explains my choice of EPROMs. Note, however, that there are

Program listing to generate ROM program for the CW identifier.

other ROMs that could be used. For instance, if only a single message is needed, the MM5204Q 512×8 EPROM would fill the bill nicely. If you don't anticipate making changes, then a non-erasable PROM would also work. In a pinch, a pair of 256×8 PROMs could be used, too.

Even if you do not have a programmer, many EPROM suppliers have programming facilities. Occasional ads from various individuals in the classified columns of computer magazines also offer EPROM programming.

Construction

Building the CW identifier is easy; the circuitry works at a fairly slow speed and no special precautions are needed in building it. Wire-wrapped construction would be fairly easy and very compact, but if you use one of the 2704/2708/2716/2758 series of EPROMs, then the printed circuit layout of Fig. 11 is for you. (Etched and drilled PC boards are available from Star-Kits, PO Box 209, Mt. Kisco NY 10549, for $15. Also available is 2708 and 2716 EPROM programming for $10; you supply the EPROM and the call.)

Fig. 12 is the parts layout for this board. Since this board is usable with any of the four EPROMs shown in Fig. 10, connections to pins 19 and 21 are brought out to pads and require some care on your part.

Though the circuit board layout is designed for the CW identifier, with a few minor trace cuts it could also be used for the touch-tone sequence detector or for many other micro-programmed sequential controllers. So keep this idea in mind next time you need a controller for some project. It's a winner! ■

Messages from Station Charlie

—when wireless meant life or death

Author's Note: Much is written about transmitters, receivers, antennas, and all the hardware and software of the world of radio. Less is written about the messages made possible by them. This is natural when a W1 writes with pride about his brand-new Superbang 42X and his QSO with a ZL via SSTV on 10.5 GHz using bedsprings for an antenna. We *know* what *his* message is: *"I am using a Superbang 42X with bedsprings for my antenna. . ."* ● There are times, however, when *messages* are the real point—as in the cases of emergencies and disasters. And certainly it was one of those times at Station Charlie, where messages helped win the big war and kept alive the courage and hopes of men and women in the most desperately lonely of personal wars—those fought by secret agents. ● Some names, places, and times have been changed, but this is a true story. ● Many thanks, for their help with technical information, to George Fogarty (ex-W2LHC, ex-JA2AD), Stan Willard W9JAS (ex-W9GSE), and Ed Clinton W8STP—formerly Technical Maintenance Officer, Chief Signalmaster, and Signalmaster, respectively, for Station Charlie. ● This material has been reviewed for security by the Central Intelligence Agency and the National Security Agency. ● Copyright 1981, Richard Phenix: All rights reserved.

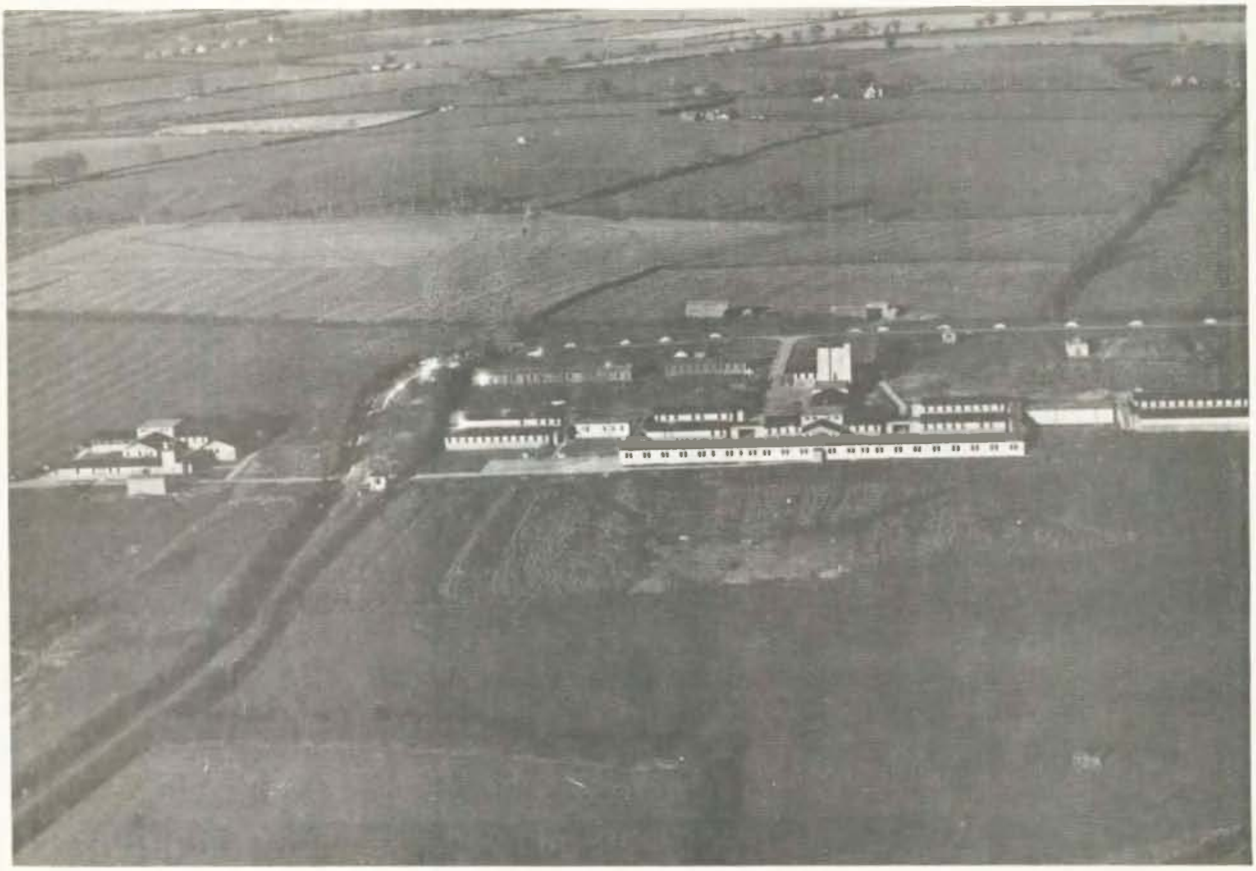

Photo A. Station Charlie, Buckinghamshire, England, 1944.

It is 1944. Station Charlie covers the top of a low, rolling hill in Buckinghamshire, England, not very far from Oxford (Photo A). The station's operations buildings, which make up the "security area," are clustered together at one end of the encampment apart from the rest. Here are housed the communications activities, running 24 hours a day; they are the reason for Station Charlie's existence.

Between them and the "housekeeping area" of mess hall, motor pool, administration buildings, officers' and "other ranks'" barracks, runs an old country lane, now closed to public use for the duration by guard posts at Charlie's boundaries, much to the annoyance of the local fox-hunting club. The lane runs from nowhere in particular at one end to the Sow and Pigs pub at the other, in the small village of Poundon. It is possible for perhaps thirty people to be in the pub at the same time—if they watch out for each others' elbows.

But the some fifty men and women working in the operations buildings are too busy to worry about that, and the three hundred or so in the rest of the camp are either sleeping or about to sleep or waiting to go on duty. Station Charlie is an isolated post and, anyway, the job's the thing.

In fields beyond the operations buildings, receiving antennas lift their slender, quadruple-guyed wands 120 feet into the air; a few miles away, lines of equally-tall transmitting antennas march across other fields in the directions of France and the Scandinavian peninsula (Photo B).

One of several stations operated jointly by American and British intelligence agencies, Station Charlie is, in this critical year of World War II, a communications base for secret agents inside Axis-dominated territories. It is receiving their often-faint Morse signals, deciphering and decoding the messages, and transmitting them by teleprinter to London. It also is encoding and enciphering teleprinted answers or questions from SHAEF (Supreme Headquarters, Allied Expeditionary Force) received over the same secure land lines and is sending them booming out over the English Channel and the North Sea to, it is fervently hoped, alive and receptive ears (see Fig. 1).

The Station At Work

Little was spared to make Station Charlie a reliable link in the communications chains leading from its assigned men and women in the field—close to 100 at times (the "outstations")—to the guarded offices of war planners. There was no James Bond atmosphere at Charlie; we left that to the masterminds behind unmarked and inaccessible doors on London's Baker Street. Our job was to listen for even the faintest whispers of signals, to hear them *at once*, to copy them without error *the first time around*, and to allow the vulnerable senders to get the hell off the air *quickly*; then to translate Morse code groups into clear text in one or another readable language *quickly*, and fire them off to London *quickly*; it was to encipher clear texts from London accurately and *quickly*, to send code groups with copperplate hand *fast*, but not too fast, and, again, to get the hell off the air. (See Photo C.)

Speed and accuracy. It was our job to provide both. Sitting comfortably on our hilltop, safe and well-fed in the peaceful rolling countryside, speed and accuracy were the priceless contributions we

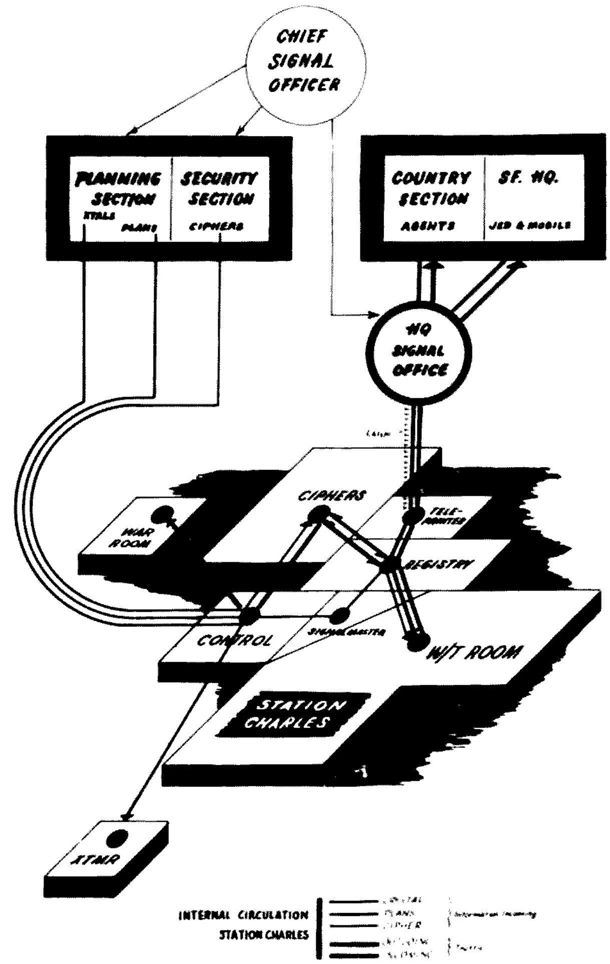

Fig. 1. Operational layout of Station Charlie. British terms are used (W/T—wireless telegraphy, for radio, etc.). "Plans" included calls and schedules (skeds) for transmissions. Agent messages were routed to "country" intelligence offices (Norway, France, etc.) and/or to S.F. (Special Forces) offices during pre- and post-invasion weeks.

Photo B. Transmitting antennas.

could make to those out in the dangerous occupied areas who rarely could provide either; they sometimes died because they could not.

Equipment

It was to preserve lives as well as to make possible the gathering of the highest class of intelligence that the best-available equipment was used. Receivers were the kind that most prewar amateurs wanted and few could afford. There were AR-88s, two kinds of Hallicrafters rigs, the Hammarlund HQ-120X, and National HRO-5s. Recording equipment was by Creed—beautifully-made British units. (This also was used to "fingerprint" agents for comparison purposes in cases where later it was suspected that the Germans had captured an agent and were using his equipment to try to send us misleading information.)

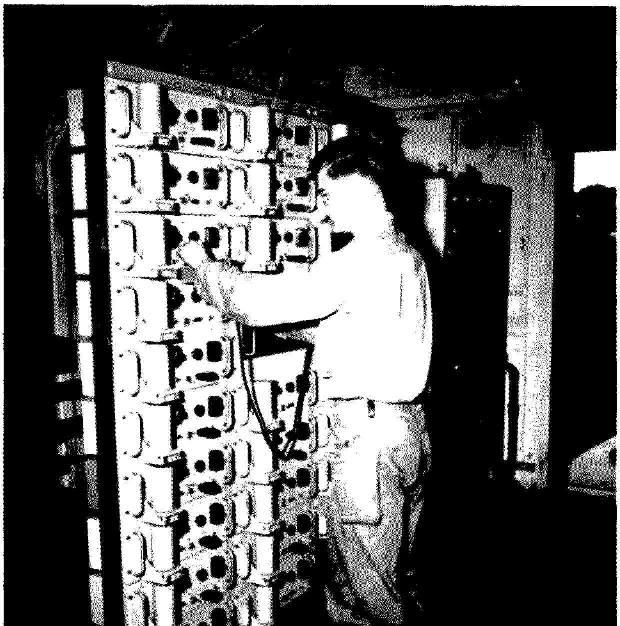

Photo E. The wideband amplifiers were a technical curiosity at Station Charlie, as described in the text.

Good receiving units were essential if transmissions from the field were to be picked up with any reliability. While the equipment of the agents ranged from bulky hand-cranked-generator sets to the then-amazing British fibre-suitcase units, it was mostly the latter Charlie listened for. These measured 12" × 18" × 5" and contained the transmitter, receiver, and power pack with built-in battery charger! The battery was a 6-volt motorcycle type with vibrator high-voltage supply.

Charging was *never* done while transmitting—that was an invitation to German DF units to join the party! All the Germans had to do—and did, in early days—was to cut power to an area, sector by sector, briefly, until transmissions were interrupted, and then move in fast to encircle the sector pinpointed.

Transmitters, located in separate buildings a few miles away (Photo D) and connected through land lines to the Control Room, included a 400-Watt RCA, 3-to-5-MHz unit, using 807 crystal oscillators and 813s in the output stage (probably ET4036s). Tape-sending equipment was principally McElroy—the prewar code-speed champion and manufacturers of speed keys—and also Creed and Teletype™.

The RCA transmitter was hellaciously hard on crystals, and one modification made at Charlie was the addition of low-power crystal oscillator doublers ahead of the 807. (Some parts were obtained in typical war-time fashion by fast shuffles—there may still be an American power mower used to cut English grass on the grounds of a now-retired British officer who helped us out.)

A particularly interesting unit was the wideband amplifier (Photo E) of which we had two. Designed and built by the British, each consisted of ten reasonably conventional low-power, crystal-controlled exciter stages, all fed into a wideband rf amplifier; sixteen or twenty 807s in push-pull parallel kept the input and

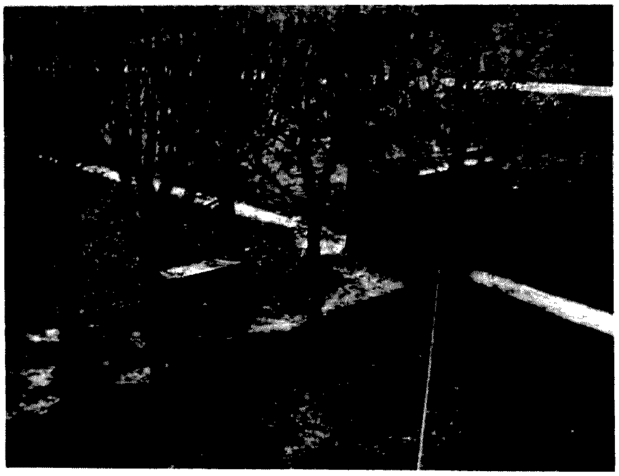

Photo F. One of the mobile units (an SCR-399) at St. Cloud, outside of Paris.

Photo G. The Cipher Room's small war map of France, with Jed locations indicated by map pins along and beyond fighting fronts. The pin nearest the map's center is close to Chateauroux and probably was for Hamish (see text).

output impedance low. (And the efficiency—about 50 Watts per channel!) Thus, coax could feed the input and the output could go directly into terminated rhombic antennas (about 300 feet on a side) pointed in the right direction. Because of the power gain of the rhombics, the effective power per channel was 350 Watts.

Transmitting antennas were mostly delta-matched doublets on poles 60 to 120 feet in height. Station Charlie crews *often* took these down and altered them to conform to changes in transmitter operating frequencies and outstation locations!

Receiving antennas were coaxially-fed doublets patched into individual receivers or, via a vacuum-tube isolation amplifier, to groups of receivers.

The Agents

Station Charlie's special task was to work with, first, agents in Scandinavian countries (our "Country Section"—see Fig. 1), second, with the Jedburghs (Jeds), agents parachuted in ahead of invading forces, and, third, with mobile stations which moved with various army units (Photo F). During invasion days and the weeks following, Jed intelligence was hotlined to the armies, giving them remarkably up-to-date information on what lay immediately ahead. The map in Photo G shows the locations of Jeds geographically and with respect to Allied forces and French resistance groups. (At the time of this photo, the Allies had penetrated well into France, leaving the northwest area clear of Jeds. Those who had been overrun were returned to England—if they had survived—and were readied for other parachute drops.)

Each outstation had its own codes, crystals, transmission "skeds" (see blackboard in Photo C), and secret security checks. The absence of the last in any message was supposed to alert us that the agent had been compromised—that it was the enemy now using the codes and equipment. While both sides had some successes in this sort of counterintelligence, usually the absence of the check was due to forgetfulness or the great pressures under which agents worked in the field, leading them to bare-bones operations—and to hell with procedures.

Those pressures were sometimes so unbelievably extreme that it seemed almost miraculous when things worked out reasonably according to plan. Parachute drops could miss the right area entirely, suitcase transceivers could bounce shatteringly off rocks (or go "glub" in a lake), the local reception committee might not be there but a German unit just might be, leading to an abandonment of all equipment and (hopefully) a headlong dash to escape. Sometimes it was up to us at Charlie to try to sort out what had happened when the wrong agent came in on a sked or somebody else's code was used in an emergency.

One French agent I met in Paris later in 1944 told me of his months in the Ardennes forest in 1943 and 1944. Regularly on the jump, he said—swimming rivers "while the Boche fired at me" (and once escaping in an empty wine barrel on a friendly farmer's cart)—*Citron* spoke with dry humor of times when he figured that even his friends were against him: winter clothes parachuted to him in July . . . one supply drop which consisted of four canisters containing nothing but lampshades . . . and a day when an urgently-important operational message was due from England and, despite German activity near his hideout, he kept his radio sked and received just one message, saying (roughly): *After due consideration, our staff has concluded that the Maquis group you are with should be named after the French -th Regiment that fought in your area.*

Citron also told of the intensely emotional experience of his first radio contact after jumping into France (he worked a sister station of Charlie's). This backed up what we had been told by the Chief Signal Officer (London) about our own agents—that the first contact with us was universally reported to bring an emotional high unsurpassed by any they experienced thereafter. We all believed this, at Station Charlie, and it gave us additional motivation to do our jobs well, but for me it may not have been until ten years later that the *full* meaning became clear—when I had occasion to hear from another agent about the magic of that first contact.

etc.

Fig. 2. The one-time pad ciphering table (E over d equals Z, etc.). Agents' copies were printed on handkerchief-size pieces of silk. The plan was to do it in invisible ink, to be developed in the field in plain water in which chemically-treated shoelaces were to be soaked. I suspect this was just one of those dramatic notions never carried out. The table itself was not secret, and a handkerchief made of silk would all by itself have alerted any German.

(a) EBDAD BJCGH CBGAB EBHFA

IZIZ—Infiltration-completed-into-area-occupied-by-enemy

YHYH—700 and

XKXK—50

ZLZL—Continue spelling for rest of message.

Fig. 3. The received message (line a) written over lines in our copy of the agent's one-time pad (his pad pages were burned as he used them) was deciphered by use of the table in Fig. 2. Line c then was decoded using the table shown in Photo I, excerpts from which are listed here.

Swan

"Oh, how many tears I fell that day!" was the way *Swan* expressed herself to me on that occasion—near the end of the few days I ever knew her as more than just a code name. The radio operator for one of the Norwegian units (all of which were known by bird names), much of her war had been spent in the Stavanger area. For a week after her unit was activated, she had been unable to contact Charlie. Then, in a saeter, much higher up above a small fjord than she had been before, tired, discouraged, wet, hungry, and fearful of the German occupation forces—for they surely knew by then that her team was in the vicinity—she tuned in on her assigned frequency at her assigned time and in came the booming signal from Station Charlie: STW STW STW de CAM CAM CAM QRK? QRK? QTC QTC K K repeated over and over as the perforated-tape loop (Photo H) fed through and our W/T operator strained his ears anxiously for the response: CAM de STW QRK . . .

Photo H. The Perforator Room, in Registry, stored the tape loops with the agents' calls. Perforated tape was state-of-the-art in 1944. We had some of the earliest belt recorders, but they were a total loss at that time.

I like to think that I remember that day, 37 years ago, and maybe I do. I know I told *Swan* that I did—and meant it—but at Charlie we had many such happy first contacts with agents, whereas for *Swan* it was, of course, the only one, and tears glistened on her cheeks again as she relived it.

"You were all we had," she said. "My God, that feeling of *not* being alone after all! We got our courage back . . . you [Station Charlie] were *there*, and you never let us down!"

So far as we could know, Station Charlie never let anyone down. There was a set period of time for listening for an agent to keep a sked, at the end of which the pragmatic assumption was that he was blown—dead or captured—and we could stop sending out our call on a listening watch. Somehow, however, we did not stop unless we had other intelligence that the agent was, indeed, lost. The Charlie W/T operators hated to give up, and it was well understood when some of them used off-shift hours to listen for signals which usually never came.

Hamish

Hamish was one of the Jeds who failed to keep a sked one day. According to the location of his pin on the war map in the Cipher Room (see Photo G), he was operating in a particularly hot area. (This map was backed up by very large-scale maps to help us decipher garbled transmissions which often included critically-important place names. Thus, we could advise London that "German tanks massing at Chatsauvyhf" undoubtedly referred to Chateauroux, not Chateauneuf, which was more than 100 air miles away from the agent's location.)

As with other agents we presumed were lost, Station Charlie kept *Hamish* "alive" beyond the required period.

I don't remember what it was that made *Hamish* special to me, but he was, and I know that he was particularly in my mind some years later when I met and chatted with a German whose war job had been DFing Allied clandestine transmissions in the Chateauroux area; he told me with pride of some of the successes his unit had enjoyed. But I never mentioned *Hamish*—or Station Charlie—to him.

The Cipher Section

The W/T link was not the only one which broke on occasion. It happened sometimes that a message came in which could not be deciphered. We hated to ask outstations to expose themselves to DFing by repeating transmissions, but when one had come in five by nine that wouldn't break, we could be sure that the trouble was in the ciphering process.

That sort of trouble belonged to my department, the Cipher Section. As the Signalmasters felt about their operators, so I felt about the cipher crew. I couldn't ever say enough in praise for the more than a hundred service men and women who worked the Cipher Room. Most were members of a British women's auxiliary—a famous one dating back to the Boer War. Mostly English or Scots, many had good personal reasons for dedication to the job: husbands, family members, and friends who were out there somewhere or who had already died in combat or in air raids. A few of them had *memorized* the deciphering table for the one-time-pad cipher system—this consisted of 676 three-letter combinations! (Fig. 2 is of a made-up portion of such a table, showing only 100 of the three-letter combinations.)

Given a priority message hot from the W/T room—line (a) in Fig. 3—and the correct copy of the one-time pad (page after page of random 5-letter groups) on which the agent had enciphered his message—line (b)—there was usually someone on duty who could write the first over the second and come up with the clear text—line (c)—without looking at the table. (Portions of the clear text sometimes were also in code—as in the Fig. 3 example—and had to be decoded using another table, part of which is shown in Photo I; nobody ever even tried to memorize that one, which yielded thousands of meanings from its four-letter code-group combinations from AAAA through ABAB through ZYZY to ZZZZ!)

We also had specialists who made possible the untangling of messages which came in not only in a language other than English but also via the horribly complicated double-transposition ciphering system used by Scandinavian agents. Based on a memorized key, it had obvious security advantages over code books and tables, but it worked satisfactorily only when, well, only when it worked satisfactorily! Unlike the one-time pad system where each letter was, in effect, independently enciphered by the substitution of another letter, in this system all the letters remained themselves but were by prearrangement twice transposed in their relationships with each other—jumbled about, in other words.

In the worst case, one single misplaced or misnumbered letter in the key could make a stew of an entire message. Fig. 4 shows an example of a message correctly enciphered—(a), (b), and (c)—and also, in (d), (e), and (f), what can happen during deciphering when only seven letters had been transposed incorrectly. (Fig. 5 is the poem used as the key in this example. It is one that I wrote for myself in 1943 when I thought I was going into North Africa with a team; I shall never be able to decide whether I am glad

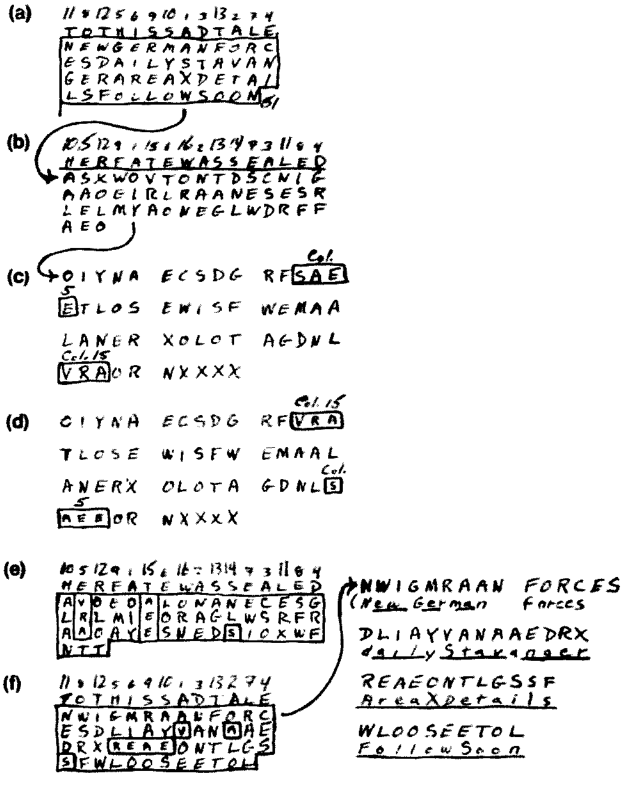

Fig. 4. This shows how an agent enciphered his message number 18 (using, therefore, in a prearranged way, lines 1 and 8 of his memorized poem—see Fig. 5). Note in the second box (b) how sloppy writing of column numbers 5 and 15 could result in misplacing seven letters: (c) is correct; (d) is wrong, resulting in garbled deciphering in (e) and (f) and the thoroughly loused-up result (capital letters). The misplaced letters are boxed here to show how they moved around. This type of error happened to be ho-hum common and gave our experts no problems!

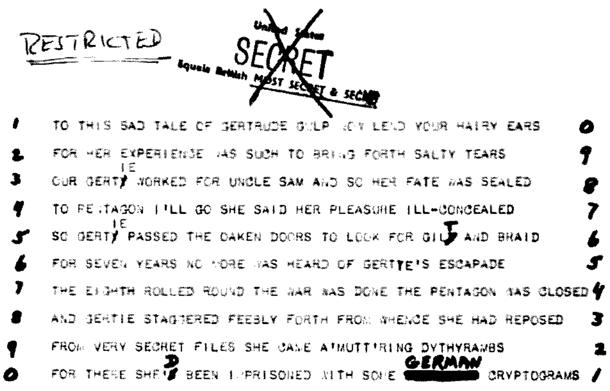

RESTRICTED

United States SECRET Equals British MOST SECRET & SECRET

1 TO THIS SAD TALE OF GERTRUDE GULP NOW LEND YOUR HAIRY EARS 0
2 FOR HER EXPERIENCE WAS SUCH TO BRING FORTH SALTY TEARS 9
3 OUR GERTIE WORKED FOR UNCLE SAM AND SO HER FATE WAS SEALED 8
4 TO PENTAGON I'LL GO SHE SAID HER PLEASURE ILL-CONCEALED 7
5 SO GERTIE PASSED THE OAKEN DOORS TO LOOK FOR GILT AND BRAID 6
6 FOR SEVEN YEARS NO MORE WAS HEARD OF GERTIE'S ESCAPADE 5
7 THE EIGHTH ROLLED ROUND THE WAR WAS DONE THE PENTAGON WAS CLOSED 4
8 AND GERTIE STAGGERED FEEBLY FORTH FROM WHENCE SHE HAD REPOSED 3
9 FROM VERY SECRET FILES SHE CAME A'MUTT'RING DYTHYRAMBS 2
0 FOR THERE SHE'D BEEN IMPRISONED WITH SOME GERMAN [redacted] CRYPTOGRAMS 1

Fig. 5. My own poem (obviously), used only once to check it out. Yes, dythyrambs is spelled wrong; but I've always been sorry for people who have so little imagination that they can spell a word only one way (so said Mark Twain).

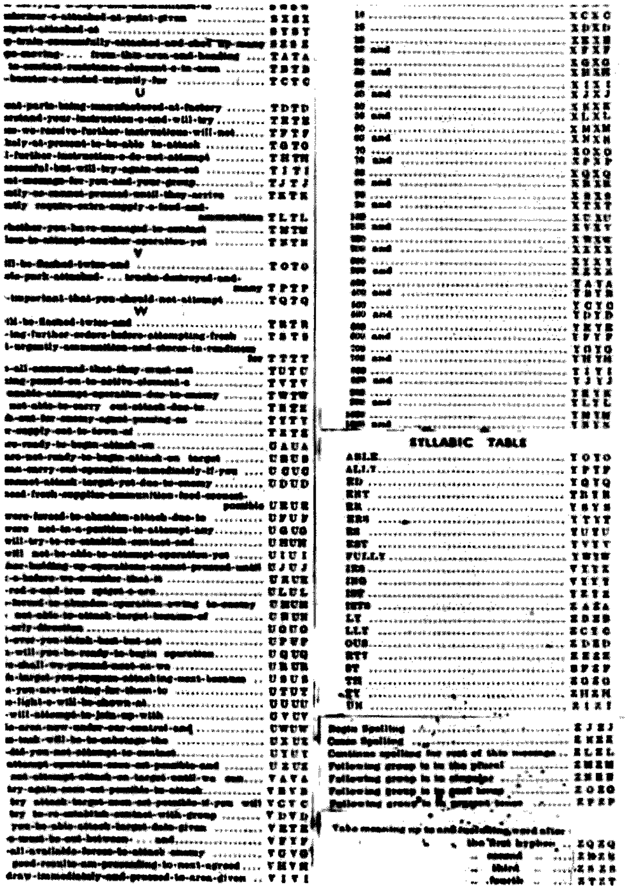

Photo I. Part of the code table used by Jeds. This was another refinement that was more accurately thought of as a complication. Designed to shorten messages and, therefore, precious transmission time, agents usually chose to risk longer times on the air in favor of shorter times for the enciphering process.

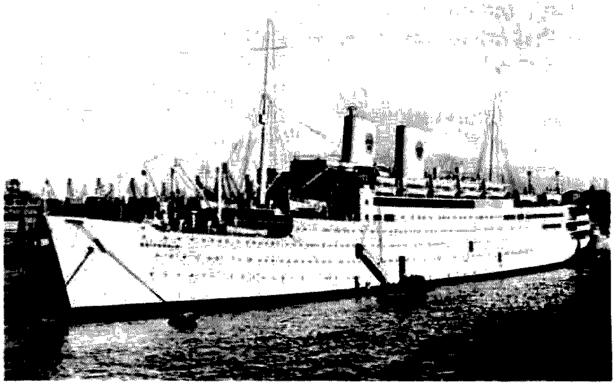

Photo J. The Motor Ship Gripsholm *of the Swedish-American Line was famous for her many mercy and diplomatic voyages. She later became the* Berlin *for the North German Lloyd Line.*

or sad that that assignment was changed!)

Visualize, if you can, *Swan* sitting in a leaky saeter hut with stub of pencil and soggy paper, half-frozen, remembering her own poem—was it *imorgen* or *imorgon?* (one being Norwegian and the other Swedish, for "tomorrow")—remembering whether it was message 17 or 18 (which determined which lines of the poem to use), constructing her squares, numbering the columns (the first a is 1, the second is 2; the third, 3; no b or c, so d is 4, etc.), writing directions to a safe house for a new agent soon to be parachuted in (GA FEMTE GATE TIL VENSTRE OG DEN SJETTE TIL HØIRE), removing the letters vertically from the first square in column-numbered order and writing them horizontally in the second square, removing them again, vertically and so on, all the time listening for the always-to-be-feared sound of approaching German DFing units. *Swan* did her work correctly for the most part. I couldn't have! Could you?

Add to that all transmission problems, QRM, QRN, etc., and it was a wonder that we managed to untangle (*without* computers) nearly all the "undecipherables." And that included one which took a score of us weeks to break—and earned us a commendation even though it turned out to say the war-time equivalent of something like "Having wonderful time, wish you were here." After all, it *could* have been important!

It is a temptation to write on and on about the little corner of the war which was Station Charlie and the messages we sent and received, but by now you should have the picture of intensely dedicated W/T operators, cipher personnel, transmitter technicians, controllers, perforators, teleprinter operators, registry clerks, and maintenance technicians, all of us so awfully tenuously linked to the lonely souls to whom our work literally could mean the difference between their eventual return to England—and living—and capture, possible torture, and death.

Ten Years Later

It is 1954. The M/S *Gripsholm* (Photo J) is plowing her slow and steady way through the Atlantic. Fine on the starboard bow is Dunnet Head at the tip of Scotland, around which is the North Sea—one of the most crowded of graveyards for ships of war. The *Gripsholm* is headed for Gothenburg, Sweden, and then the port of Bremerhaven, Germany.

It is the dawn watch, and Second Officer Kurt von Meeteren is on the bridge; Acting QM Ernst Weiss has the wheel (Photo K). Von Meeteren was commander of the German submarine U399 for part of the war, and then of U3021, which, on command at the end of the war, he scuttled in the North Sea. Also on watch is another Quartermaster, a bosun's mate, and two ABs—one on lookout in the foremast and one on fire guard.

Throughout the ship, men once of the German Navy are on duty, for this is a hand-picked crew: It is the maiden voyage of the *Gripsholm* under charter from the Swedish-American Line by Norddeutscher Lloyd; it is the first passenger ship since WW II to fly the German flag.

Most of the passengers, however, are Scandinavian, and they had not been told that the only Swede on ship duty would be the Chief Engineer, Eric Toll. It is a difficult experience for many of them—bitterly so, for some—because the war is not that far in the past and no part of it has been forgotten. The German crew is aware of this—it was their war, too, and they were defeated—and members are keeping as low a profile as possible under the circumstances. It is *not* a happy ship.

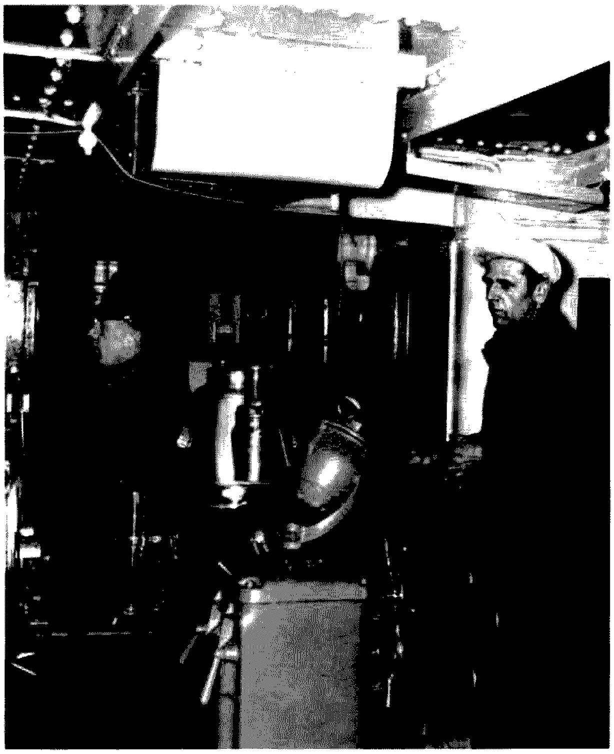

Photo K. On the bridge of the Gripsholm, *2nd Officer Kurt von Meeteren stands the dawn watch, with Acting QM Ernst Weiss at the wheel.*

Photo L. Chief Radio Operator Hans Kleiber in the Gripsholm's *radio shack.*

At this pre-dawn hour, most of the passengers are in their staterooms for the night, forgetting in sleep the German presence that they had been trying to ignore during the day. Some, however, are still up and enjoying each other's company. There is one such group in particular, in one corner of a tourist-class lounge—a Finn, three Swedes, two Norwegians, a Dane, and an American. As a sort of goodnight salute to each other, they are singing their national anthems, one by one. All of them know them all—except for the American. He knows only his and is feeling rather sad about that.

Four Who Were There

One. I was the American and was on my way to Frankfurt, Germany, to be a consultant for a refugee program. By day, I "worked" with the German officers and men, for I had been given the run of the ship in order to write a story about the *Gripsholm.* (By night, I "played" with my fellow passengers.)

Two. Thus, I had met and interviewed Chief Radio Operator Hans Kleiber (Photo L) who told me of his DFing of Allied agents in France; it was then that I had wondered about *Hamish.* Could Kleiber's unit have been responsible for his disappearance?

Three. Four. And I wondered even more—but *only* to myself (and *never,* before now, to more than a very few)—when, after trying to sing Scandinavian national anthems and joining in on what was supposed to be the last skoal of a joyous night, two of my favorite people there, Christi and Dag, turned out to be *Swan* and *Hamish.*

Never before nor since has there been such a moment in my life.

During the hours we had spent together on board, we had gradually come to know each other, of course, and, as reserves had dropped away, we had talked more and more about the war years and our very personal experiences. I do not remember exactly how the final recognition came about. I never will; it overwhelmed us all too suddenly. We were talking about Norwegian resistance groups, I know, and I think Christi said something like "... when I was with *Swan* ..." and I know my jaw dropped. I managed to say some strangled words about Station Charlie ... Christi looked at me incredulously ... Dag said something like "Oh, my God!" ... and then, "I'm Hamish ...! and I said, "Oh, my God!"... and the three of us began talking, laughing, and, oh, yes, crying, all at the same time ... and Dag ripped off his shirt and showed us his scarred back where the Gestapo had had him flayed ... after he'd been DFed by the Germans ... and Christi told us of her very first contact with Station Charlie, and she said, *"Oh, how many tears I fell that day ... !"*

Conclusion

Yes! Sometimes the messages *are* the most important part of radio communications, amateur or otherwise. And the sounds of such communications can echo down through the years, forever.

I doubt if any of us from Station Charlie can hear Morse code now without remembering, and being grateful for, the small and quiet roles we were privileged to play in those great happenings of WW II, when there were more of the world's people than ever before or since united in a shared belief. ■

The Great Compromiser

—Henry Clay, eat your heart out

The search for better antennas has been going on ever since Hertz made his original experiments. He, incidentally, came up with findings that many people think were not known until many decades later. In fact, very few new facts relating to antennas have been discovered in the past 75 years; even fewer in the past 50 years. That doesn't mean, however, that the wheel has not been reinvented countless times!

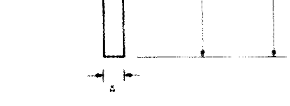

Fig. 1. Wideband doublet antenna (not to scale). Design example: lowest operating frequency—7 MHz; range—7-21 MHz; A = 42.6 cm (1.4'); B = 14.3 m (46.5'); resistor—600-Ohm noninductive. For transmitter power output of 100 Watts, use at least 60 Watts dissipation.

Of late, there has been a resurgence of interest in a type of antenna often used by military stations during the Hitler War. It was desirable because it avoided losses attendant to the use of Marconi-type antennas. Marconis, unless used in conjunction with excellent ground systems, have an inherent loss that sometimes is unacceptable. This led to research for a system that would avoid such ground losses. The task was further complicated by the fact that military high-frequency communication often was required to operate over a wide range of the HF spectrum.

To reach an acceptable solution of this complicated problem, an old idea was resurrected from the dustbin, dusted off, and slightly modified to meet the exigencies of the situation. It was not an ideal solution. But, then, just what is perfect?

The slightly-compromised solution was a wideband-terminated doublet. Some persons prefer to call it a "squashed rhombic." It has had a number of other nicknames.

The antenna, as shown in the diagram, is a folded, resistance-terminated doublet, one fed with a 600-Ohm balanced transmission line. The terminating resistor may be either a noninductive resistor, suitably protected from the weather, or a 600-Ohm transmission line constructed of high-resistance wire. Alternatively, one could run a normal-loss 600-Ohm line to a convenient location for the terminating resistor. Because of the fact that the resistor must be capable of dissipating 60% of the rf energy supplied to the antenna, its physical size may make it not practical to mount the resistor directly on the doublet.

The length of the doublet is one-third of a wavelength, and the space between wires is one-hundredth of a wavelength. These two dimensions are for the lowest contemplated operating frequency.

A test of an antenna of this type by the US Navy Electronic Laboratory showed a transmission line standing wave ratio of 1.4 to 2.6 over a frequency range of 4 MHz to 22 MHz. Antenna efficiency varied from approximately 20% to 60% over the quoted range. Peaks in radiation efficiency were noted for frequencies at which the antenna was a quarter wavelength and three-quarters wavelength. Below one-quarter wavelength, the radiation efficiency dropped rapidly, but above that point the efficiency dropped more slowly and reached a minimum at a frequency corresponding to one-half wavelength.

Although the efficiency of the wideband doublet is less at any given frequency than that of a conventional half-wave doublet at its resonant frequency, the advantage of wideband operation may outweigh the loss. Translated into dB drop on a receiver's S-meter, the loss is less impressive!

The directional characteristics of the wideband

doublet are similar to those of a conventional doublet. The antenna may be tilted (that is, mounted as a sloper) to have a radiation pattern more nearly nondirectional. A moment's reflection will show you that a transmission line to a sloper would be much easier to install than one to a vertical.

Note that a balanced feedline is required. It's possible, of course, to use coax feed . . . if you're prepared to design and construct a weatherproof device that'll perform the dual functions of impedance transformation and unbalanced-to-balanced.

The military of both this country and Great Britain made extensive use of this type of antenna, mostly for point-to-point communication circuits.

To sum up, here's what you get: a wideband antenna that'll work moderately well over a broad frequency spectrum. The vswr on the feedline would not be low enough to make a fixed-tune, solid-state transmitter happy, but would be acceptable by almost all transmitters having a tuned output stage. An impedance-matching device with balun functions would be needed to mate the 600-Ohm line to the input of most transmitters. It would work the new bands as well as those presently allocated (with proper design, of course).

Against these advantages, you must weigh these considerations: a drop in radiation efficiency, the necessity of having a terminating resistor, and a feedpoint impedance not compatible to modern transmitters.

You make your choice. ■

Touch-Tune with Thumbwheels

—cast away darkness

Ash Nallawalla ZL4LM/VK3CIT
53 Chirnside Avenue
Werribee, Victoria 3030
Australia

It was well before 1977 when my friend, Don ZL4DS, designed a synthesized transceiver using BCD thumbwheel switches for direct programming/readout. (That's another story.) A receive-only version, the KR 1000 was built and a prototype, shown in Photo A, was to be sent for evaluation to Arthur Cushen, the famous blind shortwave listener.

Photo A. Direct thumbwheel-switch readout on the prototype KR 1000. (Photo by ZL4LM)

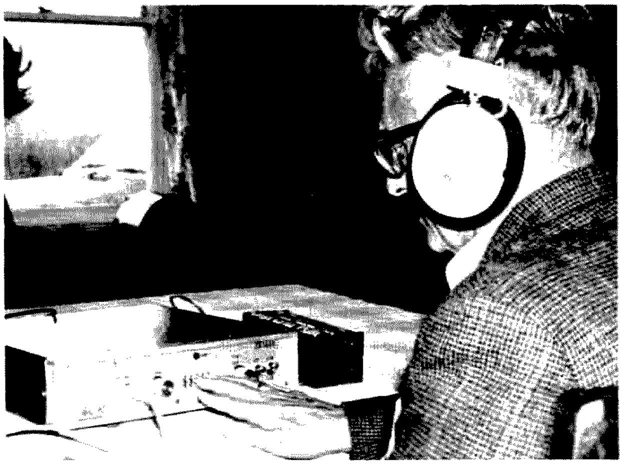

Photo B. Blind SWL Arthur Cushen finding his first station unaided. (Photo by Leo Miezenbeek)

In the past, blind radio amateurs and SWLs have relied mainly on crystal markers or sighted spouses and friends to provide frequency readout. In recent years, several commercial aids have been marketed, but they are not always compatible with existing equipment.

I was to take the KR 1000 to the 1978 annual convention of the New Zealand Radio DX League at Tiwai Point, near Invercargill. I was trying to figure out how Arthur could "tune around" without assistance, when the idea struck me!

How about marking the thumbwheel switches in some way so that Arthur would have a starting point? The easiest method would be to file down or snip off the sharp tip of each thumbwheel switch position corresponding to zero, just enough to make it feel different than the other numbers. (Fig. 1.) A blind person could line up all the zeros and then flick down each switch in turn to arrive at a desired frequency.

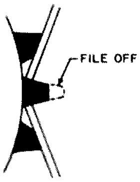

Fig. 1. Modified switch.

Arthur's face lit up when he dialed up his first station (Photo B). "For the first time in many years I have been able to tell the exact frequency of a station without the help of anyone else!" he exclaimed. Later, he wrote about his experience for SWL publications.

In 1978, there were no popular commercial receivers or transceivers (to my knowledge) that used thumbwheel switches, so I did not bother to write this article then. Today, it's a different story. There are several examples around: certain CB-to-10 conversions, Icom IC-2A, AR 240 series (in the US known as Tempo S1/2/5), etc. There must be dozens of non-amateur applications, too.

Even if you are not blind, this simple mod may come in handy if you are caught in the dark or want to demonstrate amateur radio to a blind friend, and perhaps some manufacturer could incorporate the idea as an added feature! ■

Put Talking Time on Your Repeater

—a Sharp idea

Repeaters everywhere have doodads of every sort, one of which is a time-announcement machine. Historically, these talking clocks were very expensive, bulky, and just plain hard to use. Recently, Sharp (makers of calculators, watches, refrigerators, microwave ovens, and such) introduced a talking clock. This low-priced device sells for about $79 and is just ideal for interfacing to a repeater.

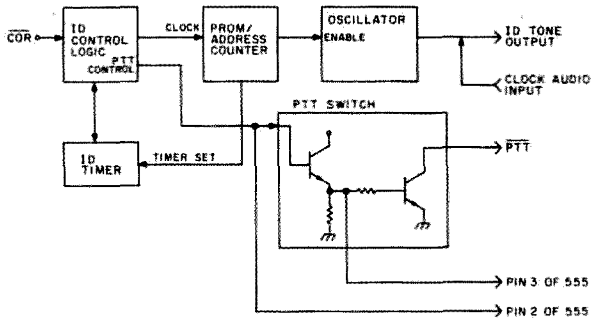

Fig. 1. Talking Time interface.

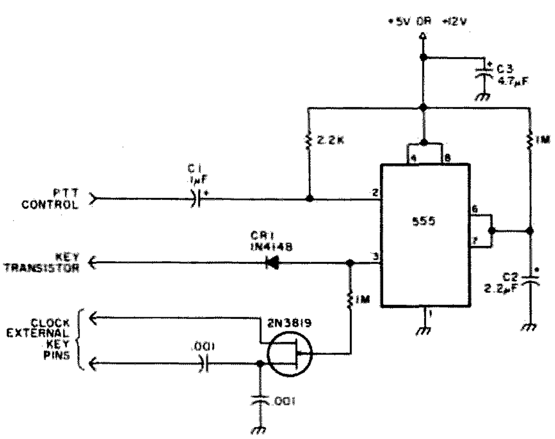

Fig. 2. Clock timer. C1 through C3 are tantalum.

About the Clock

The clock can be found in most discount distribution center catalogs. The model number is CT-660. It is a small electronic clock with a liquid-crystal display (LCD) and a small speaker on the top. The case is plastic with a metal top. All controls are on the bottom in a covered compartment except an auxiliary pushbutton switch which activates the time announcement. Power is furnished by two AA batteries. A mercury-type battery is preferred and will last about a year during normal use, but the life of the batteries will be shortened by high usage of the voice synthesizer.

Setting the time is easy. Just flip open the cover on the back, slide the Time/Alarm switch over to the left, to the Time/Set position. Press the Hour button to set the hour. Then set the minutes in a similar manner. Unlike most electronic clocks, holding the button down does not cause the clock to advance. The clock will announce the hours and minutes as you press the button. After you have the correct time, press the Set button which loads the programmed time into the clock. Failure to press the Set button will result in the time being lost when you return the switch to normal.

The regular time and alarm functions are provided as in any electronic clock, but you have several options. One option is time on the LCD without voice announcement or alarm. A second option is an alarm function that wakes you to a tune; if you fail to rise, it informs you that it is now five minutes later and you are *late*. The last time option is the alarm previously described, plus half-hour and on-the-hour automatic time announcements. Other functions besides time and alarm are talking timers (5 minutes and 30 minutes) for you darkroom people and stopwatch functions for you joggers.

The most interesting thing about the clock is the voice. It is produced by a read only memory (ROM) containing the voice pro-

gram, a digital-to-analog (D/A) converter, and clock/CPU LSI chips. The voice is a digital recording of a male voice. The person whose voice Sharp used to make the ROM recording was very articulate in his enunciation of the words. Although the voice sounds vaguely like the voice of a Cylon Centurion from "Battlestar Galactica," it is very easy to understand. To be fair about it, though, it is not as bad as one might imagine. Matter of fact, it is better than most computer voice synthesizers that I have heard, and the whole thing is only about ¾" high, 2" deep, and 4" wide. It is amazing that it can do so much and be contained in such a small package. It is just the thing to round out your package of bells and whistles on your repeater.

The Connections

Naturally, merely placing the Talking Time atop the repeater cabinet is not all the interfacing required. The problem is to connect the audio from the clock to the repeater and somehow to trigger the voice when you want it to give you the time. On our 146.22/.82 repeater here in Albany (a Motorola Motrac), a couple of us decided that we wanted the time to be announced immediately after the ID.

Fortunately, the clock has very easy hookup points. All that is needed to trigger the voice is a short on the "external key" pins Sharp thoughtfully located on the left side of the case. Audio is brought out by either making a small hole in the case or by soldering wires to the external key pins inside and running all the wires out the hole already in the case. Internal connections consist of: 1) A wire connected to the negative battery terminal; 2) A wire connected to the low side of the speaker; and 3) A wire connected to each of the external key pins.

The only difficult wire to locate is the low side of the speaker. To locate this connection, position the clock with the volume control on your right; with the top off the clock, locate the two speaker wires. I might note at this point that it is somewhat difficult to remove the top cover of the clock. Remove the three screws in the case—one is visible, one is in the battery compartment, and the other is hiding under the cover, which must be totally removed to gain access.

After the screws are out, push out gently on the inside of the battery compartment while pulling up on the top cover to pop it off the plastic tabs. Now notice that near the rear left of the circuit board is a screw that secures the board. There should be several components sandwiched in there *and* the ground wire from the battery terminal. The low speaker wire is the speaker wire nearest the screw. The high speaker wire has next to it a wire that goes across the board to a spot near the volume control. The clock that I had had an extra hole already in the board at the speaker low point and all I had to do was solder a wire in that hole. That is all there is to the clock connections.

The Interface

To make the clock operate the repeater, a small interface had to be constructed. Wishing the time to be announced after the ID meant that a signal from the ID could start the time sequence. Not wanting to make major changes in the ID unit itself, I decided that the already existing PTT signal could be used as a trigger for the clock. In our ID unit, there is a line which goes high (+5 V dc) and turns on the keying transistor. This transistor, in turn, turns on the actual PTT transistor. Refer to Fig. 1. When the line is high, the repeater is keyed.

The simplest way to trigger the voice was to build up a 555 timer which is activated by the line going back low—which only happens after the ID. The 555 timer is set so that it is active for only as long as it takes for the time to be announced. See Fig. 2 for the schematic of the timer circuit.

How It Works

The negative transition of the ID PTT line from high to a low is coupled across C1, producing a negative-going spike. This spike triggers the 555 timer. Pin 3 of the timer goes to a high value. This high is coupled through CR1 to the base of your keying transistor to key your repeater. (The 555 timer can source 200 mA of current, so added drive should not be necessary.) Also connected to pin 3 through a 1-megohm resistor is an FET switch. The two wires from the external key should be connected as shown. At the same time that the repeater is keyed, the Talking Time is triggered by the FET switch. Audio is injected at the output of the ID unit and the volume control adjusted to control the level of the voice.

Conclusion

Get your club to get a Talking Time and add time to your repeater. It is a neat project that can be done in an afternoon without difficulty. I used a PC board but Vectorboard® could be used as well. A service manual is available from Sharp which is quite detailed in its description of the clock, including timing diagrams and a parts list. Have fun with this project! ■

SOCIAL EVENTS

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received two months prior to the month in which the event takes place.

SOUTH BEND IN
JAN 3

A hamfest swap and shop will be held on Sunday, January 3, 1982, at Century Center, downtown on US 33 one way north between the St. Joseph Bank Building and the river, South Bend IN. Tables are $3.00 each. There is a half acre of carpeted room in the same building as the industrial history museum. Talk-in on .52/.52, .99/.39, .93/.33, .78/.18, .69/.09, and 144.83/145.43. For more information, contact Wayne Werts K9IXU, 1889 Riverside Drive, South Bend IN 46616, or phone (219)-233-5307.

WEST ALLIS WI
JAN 9

The West Allis RAC will hold its 10th annual all-indoor Mid-winter Swapfest on Saturday, January 9, 1982, beginning at 8:00 am at the Waukesha County Exposition Center. Advance tickets are $2.00 and tickets at the door are $3.00. Reserved 4-foot tables are $3.00, at the door, $2.00, and on the balcony, free. Included with the ticket will be a 50¢ coupon toward a sandwich purchase. Prizes will be awarded. For more information, write 1982 Swapfest, PO Box 1072, Milwaukee WI 53201.

RICHMOND VA
JAN 10

The Richmond Amateur Telecommunications Society will hold its annual Frostfest on Sunday, January 10, 1982, from 8:00 am to 4:00 pm at the Virginia State Fairgrounds, Richmond VA. Admission is $3.00 plus a table charge for exhibitors and flea-market displays. Overnight trailer parking with complete hookups will be available at $7.00 per night. Various prizes will be given away during the day with three main prizes to be awarded at 3:00 pm. There will be approximately one acre of indoor heated and well-lighted space. Talk-in on 146.34/.94, 146.28/.88, and 146.52. For additional information, call Joe Stern W4LD at (804)-737-0333.

OAK PARK MI
JAN 10

The Oak Park Amateur Radio Club, Inc., will hold its annual Swap & Shop on Sunday, January 10, 1982, from 8:00 am to 3:00 pm at the Oak Park High School, at the corner of Oak Park Boulevard and Coolidge Highway, Oak Park MI. Admission is $2.00 per person. Children 12 and under will be admitted free. Activities will include a league table, a door prize drawing, and a raffle for YLs. There will be free parking available as well as food and refreshments. Talk-in on 146.04/.64 and 146.52. For additional information or reservations, send an SASE to Rob Numerick WB8ZPN, 23737 Couzens, Hazel Park MI 48030, or phone (313)-398-3189.

SOUTHFIELD MI
JAN 17

The Southfield High School Amateur Radio Club will hold its annual Swap & Shop on January 17, 1982, from 8:00 am to 3:00 pm at Southfield High School, 24675 Lahser, Southfield MI. Doors will open at 6:00 am for exhibitors. Admission is $2.00. Reserved 8-foot tables are $8.00 each and must be paid for in advance. Tables will also be available at the door. There will be lots of parking, food, and door prizes. For more information and/or reservations, write Robert Younker, Southfield High School, 24675 Lahser, Southfield MI 48034, or phone (313)-354-8210.

STUART FL
JAN 30

The Martin County Amateur Radio Association will hold its annual Picnicfest Hamfest on Saturday, January 30, 1982, from 8:00 am to 3:00 pm at Langford Park, Jensen Beach FL. Admission will be free. There will be picnic areas available and a playground for the children. For further details, contact Vern WA4GQY at (305)-334-6220, Don W4OST at (305)-286-0500, or Mike WA4GUH at (305)-334-6000 or (305)-878-7111.

ARLINGTON HEIGHTS IL
FEB 7

The Wheaton Community Radio Amateurs will hold their annual hamfest on February 7, 1982, beginning at 8:00 am at the Arlington Park Race Track EXPO Center, Arlington Heights IL. Tickets are $3.00 at the entrance and $2.50 in advance. There will be free flea-market tables, expanded floor space, parking, awards, and a large commercial area, including the new computer section. Talk-in on 146.01/.61 and 146.94. For commercial info, call WB9TTE at (312)-766-1684; for general info, call WB9PWM at (312)-629-1427. For tickets, send an SASE to WCRA, PO Box QSL, Wheaton IL 60187.

TRAVERSE CITY MI
FEB 13

The Cherryland Amateur Radio Club will hold its ninth annual Swap 'N Shop on Saturday, February 13, 1982, from 8:00 am through 2:30 pm at the Immaculate Conception Middle School gymnasium, 218 Vine Street, Traverse City MI. General admission is $2.50 and single tables are $3.00. Talk-in on 146.85 and 146.52. For further information, contact Jerry Cermak K8YVU, Chairman, 3905 Slusher Road, Traverse City MI 49684. An SASE will be appreciated.

MARLBORO MA
FEB 14

The Algonquin Amateur Radio Club will hold an electronics flea market on February 14, 1982, at the Marlboro Junior High School cafeteria, Marlboro MA. Sellers will be able to set up from 9:00 am to 10:00 am and doors will be open from 10:00 am until 2:00 pm. Admission is $1.00. Tables are $5.00 if a written reservation is made before February 7, 1982, and $7.50 for any tables remaining after that date. Refreshments will be available. Talk-in on .01/.61 and .52. For reservations, contact Mac W1BK, 128 Forest Avenue, Hudson MA 01749.

MANSFIELD OH
FEB 14

The Mid-Winter Hamfest/Auction will be held on Sunday, February 14, 1962, at the Richland County Fairgrounds, Mansfield OH. Doors will open to the public at 8:00 am. Tickets are $2.00 in advance and $3.00 at the door. Tables are $5.00 in advance and $6.00 at the door. Half tables are available. Features will include prizes, an auction, and a flea market, all in a large heated building. Talk-in on 146.34/.94. For additional information, advance tickets, and/or tables, send an SASE to Harry Frietchen K8HF, 120 Homewood Road, Mansfield OH 44906, or phone (419)-529-2801.

VERO BEACH FL
FEB 20

The Treasure Coast Hamfest will be held on February 20, 1982, at the Vero Beach Community Center, Vero Beach FL. Admission is $2.00 in advance and $2.50 at the door. Features will include prizes, drawings, a QCWA luncheon, and tailgating. Talk-in on 146.13/.73, 146.52/.52, 146.04/.64, and 222.34/223.94. For additional information, write PO Box 3088, Beach Station, Vero Beach FL 32960.

ELKIN NC
FEB 21

The fifth annual Elkin Winter Hamfest will be held on Sunday, February 21, 1982, at the Elkin National Guard Armory, located one mile from Interstate 77 at exit 85, Elkin NC. Breakfast and lunch will be served at the hamfest by the Foothills ARC of Wilkesboro NC and the Briarpatch ARC of Galax VA. Talk-in on 144.77/145.37, 146.22/146.82, and 146.52. For table reservations, ticket inquiries, or other information, contact Earl Day WB4GQP, 131 Harris Avenue, Elkin NC 28621, or phone (919)-835-3509.

GLASGOW KY
FEB 27

The annual Glasgow Swapfest will be held on Saturday, February 27, 1982, beginning at 8:00 am CST at the Glasgow Flea Market Building, 2 miles

REVIEW

THE AEA MBA-RO —A SECOND GENERATION MORSE/RTTY READER

RTTY/Morse-code readers are rapidly gaining acceptance in the amateur community, and for a good reason—a reader allows people to sample the activity on RTTY without making the substantial outlay required for a complete system. And while few will admit to it, there are an awful lot of people having an awful lot of fun copying CW with these things! Consequently, AEA's introduction of the MBA-RO reader came as no surprise. AEA has earned a reputation as a major innovator in sophisticated Morse keyers, so it seems logical that they would introduce an equally sophisticated code reader, and in fact they have.

The AEA MBA-RO is a microprocessor-controlled reader designed to display Morse, Baudot, and ASCII codes. While hardly the first such device available to the radio amateur, the MBA-RO incorporates several important improvements over the first generation of readers.

The Features

The MBA-RO is housed in an attractive metal cabinet, measuring 8-3/4" × 5-7/8" × 2". A thirty-two character vacuum fluorescent display allows the operator to see more of a sentence than readers which display only eight or ten characters at a time. This is useful under any conditions, but is particularly helpful when high levels of QRM make for rough copy. It's much easier to make sense out of garbled copy when several words are available for viewing.The bright blue digits make the display readable even under high ambient lighting conditions.

Underneath the display are three knobs. The one on the right is the mode and speed selector. Speeds of 60, 67, 75, and 100 wpm are provided for Baudot RTTY, and ASCII can be displayed at either 110 or 300 baud. Speed in the Morse-code position is tracked automatically, up to 99 wpm. There is a second Morse-code position that causes the speed to be displayed on the far right of the display.

On the left side of the display is the filter selector. While most code readers use only the mark frequency for decoding RTTY, AEA's engineers chose to include filters for both the mark and the space frequencies. This is the method used in virtually all demodulators designed for use with traditional RTTY equipment, and it provides more accurate decoding under high QRM conditions. Prototype samples of the MBA were capable of tuning only one shift, but two shifts are included on production models. Our test unit was equipped to copy 170-Hz and 425-Hz shifts, allowing copy of news services as well as HF ham activity. Those who live where there is RTTY activity on VHF may wish to retune one of the filter positions for an 850-Hz shift. This is a simple procedure requiring an accurately calibrated audio generator. If you don't feel like retuning one of the filters but wish to copy a nonstandard shift, you can place the filter in the CW position and decode only the mark frequenly. Finally, all filters can be switched out completely.

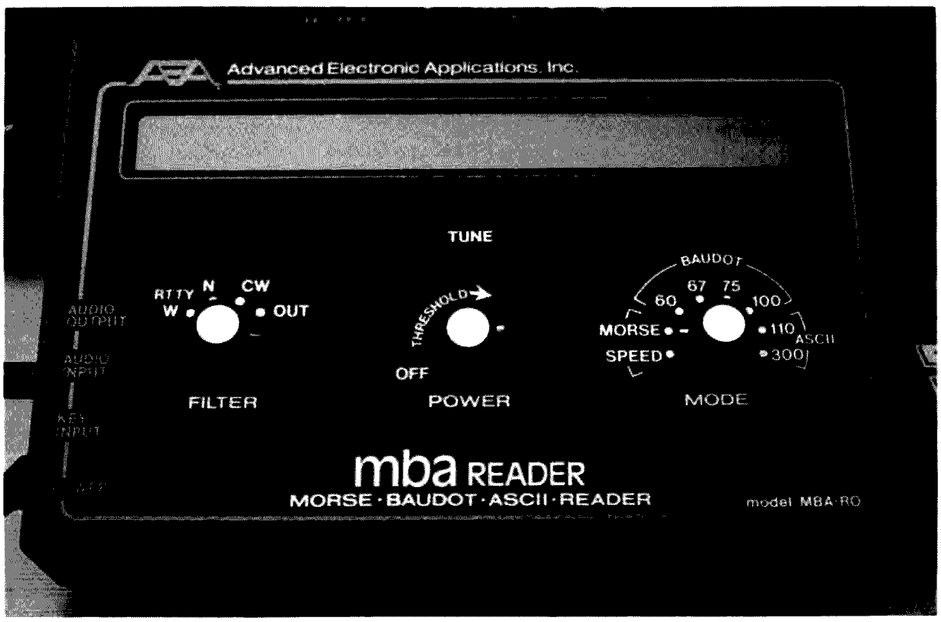
The control in the very center of the MBA is marked "Threshold," and above this are two LEDs marked "Tune." The control and LEDs are used to make fine adjustments of the MBA's filters. More on the use of these later.

On the left side of the reader is a row of jacks. There is a 13-V power input (13 V dc ± 2 V at 500 mA), audio input, audio output, and key input. The audio input can be connected to the speaker output of a receiver, and an external speaker to the output of the MBA. The key jack can be wired in parallel with a keyer, as long as it is wired for positive keying. An external RTTY demodulator can also drive the reader through this jack.

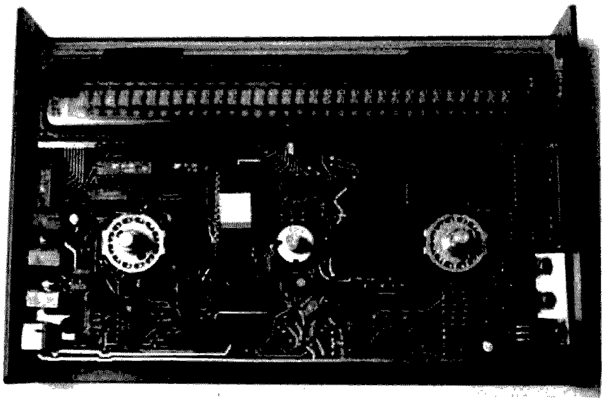
In Use

Getting the MBA-RO on line couldn't be much easier. A small bag of plugs is provided, and a few minutes spent with a soldering iron should produce all the necessary power and audio cables. Making it display off-the-air code can be a bit frustrating until you have a clear understanding of how the Threshold control works. Reading the manual should clear up any problems. I tried CW operation first, which was extremely simple using my IC-701 with its narrow audio filter switched in. The CW filter in the MBA is so sharp (100 Hz!) that I really don't need the Icom's narrow filter—I just use it to make tuning easier. The center of the filters in both the Icom and the MBA are very close to the same frequency, so peaking a signal in the center of the receiver's passband ensures good copy on the reader. I find it necessary to ride the audio gain control a little more than with other readers I have used; perhaps a tighter agc stage would help here.

The area where most readers show their limitations is in copying poorly sent CW. Most hams' fists are sloppy at best, and it is pretty hard for a small computer to decipher some of the stuff we try to pass off as Morse. The MBA produces copy as good as anything else I have used , and I've tried just about everything! I tuned across one station who was apologizing for his poor sending with a straight key—the MBA copy was perfect. Still, if an operator runs his characters together or uses highly Individualized weighting, no machine will provide good copy. The MBA follows changes in speed automatically in the Morse mode. Other systems require you to select a range of speeds or push a reset button when tuning in to another station. The speed did adjust very quickly, although it was occasionally fooled by sloppy sending. The bottom line on the MBA's CW capabilities? If someone is using a keyer and is not running his characters together, the MBA copy will be almost flawless. If someone is pretty good with a straight key, that will be decoded well, too. A surprisingly high level of QRM is



The AEA MBA-RO Morse/RTTY reader.



Inside the MBA-RO.

necessary to disrupt copy, due to the narrow internal filters.

RTTY

Performance in the RTTY mode was even more impressive than CW. The MBA copied every bit as well as most of the computer/interface combinations available. It is at a disadvantage at 300-baud ASCII because text flies by so fast you cannot read it! It is doubtful that you'll encounter much 300-baud ASCII, however.

If you have a general-coverage receiver, you may enjoy checking out the news services. AEA thoughtfully includes an order form for a book that lists the time, frequency, shift, and speed of the various services. It's definitely worth getting. If I could just interface the MBA to my MX-80 printer, I would be completely happy. Actually, an up-market MBA with a printer interface should be available by the time you read this review.

The only thing I can really complain about is the necessity of having one's receiver set in the USB position. Since most other RTTY gear is designed to operate on LSB, a switch to invert operation would be handy. This should be relatively simple to add.

Any device that contains a microprocessor emits a certain amount of noise, and the MBA is no exception. Our unit was a very early production model, and there was a just perceptible amount of hash present. AEA now has a very simple modification that reduces even this amount of noise by 40 dB or so. We didn't try the mod, but all units now available probably have the improvement already installed. Let it suffice to say that even the unimproved version is quiet enough for weak-signal work in both CW and RTTY. With the kind of antennas I've had to use lately, everything seems weak!

Conclusion

The MBA-RO performed exactly as claimed and should make an excellent shack addition for anyone interested in Morse or RTTY. The 32-character display alone gives it a significant advantage over other readers on the market. AEA will shortly be announcing a version of the MBA that incorporates a keyer and allows RTTY to be sent with a paddle—ideal for DXpeditions and maritime mobile stations! For more information, contact *AEA, Inc., PO Box 2160, Lynnwood WA 98036.* Reader Service number 477.

THE YAESU FT-290 —A MULTIMODE MARVEL MADE TO GO ANYWHERE

The Yaesu FT-290 is a unique product, which in itself is unusual in today's copycat world of look-alike transceivers. It is a synthesized multimode (USB, LSB, CW, and FM) two-meter transceiver designed for use under a wide variety of conditions. What makes the FT-290 unique is the level of sophistication packed into such a portable unit. Although it outwardly resembles many multimode two-meter rigs, this one has provision for an eight-nicad C-cell internal battery pack capable of supplying 2 Ah of current!

The Features

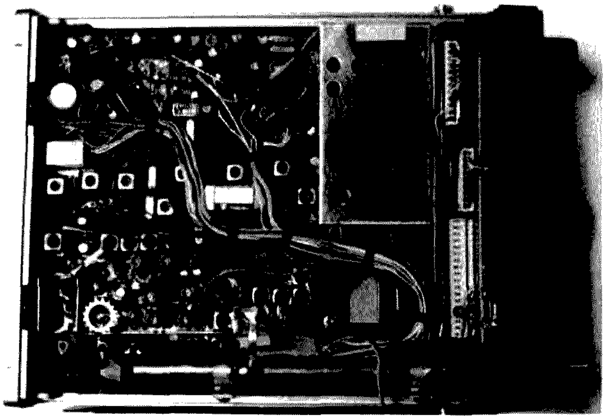
Yaesu's engineers have attempted to produce a two-meter rig that will be all things to all hams, and they appear to have succeeded. Hams with mountaintopping aspirations will appreciate the compact size and low current consumption. At 50 mA receive/800 mA transmit, those eight C-cells last forever between charges! There is an internal quarter-wave whip, but also a standard UHF connector to which you can connect a more ambitious antenna. The rig and a compact quad or yagi will be a welcome addition to many a backpacking ham's outfit.

The Yaesu FT-290 multimode 2m transceiver.

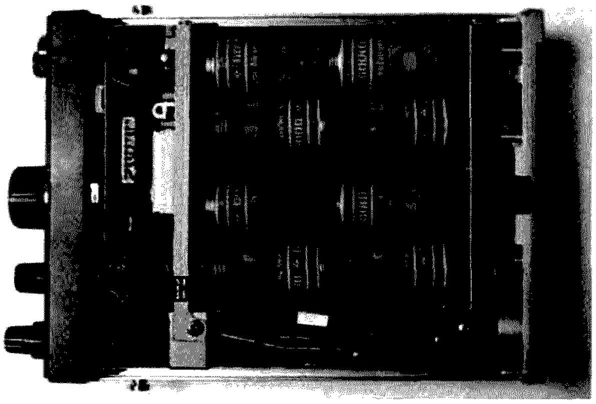
OSCAR fanatics will find plenty to be enthusiastic about as well—the FT-290 operates on both sidebands and allows the operator to change frequency while transmitting.

Operators who only do a little sideband work won't have to give up any features they've come to rely on in FM-only rigs. There are 10 memories protected with a five-year lithium battery backup, choice of stepping rates for the synthesizer, a tone burst generator, provision for an optional internal CTCSS encoder, manual band and memory scanning from the microphone, and automatic scanning for either open or busy channels. Other useful features include an LCD display, a priority channel scanning circuit, two vfo's, a clarifier, and a very attractive price tag. From an rf standpoint, the 290 keeps up with the pack—FM sensitivity is .25 uV for 12-dB SINAD, and SSB/CW is .5 uV for 20-dB S/N. Selectivity is 2.4 kHz at -6 dB and 4.1 kHz at -60 dB (SSB/CW) and 14 kHz at -6 dB and 25 kHz at -60 dB (FM).

So what's the hitch? Well, the FT-290 only puts out 2.5 Watts of rf. They had to make room for those batteries somehow! For anything but portable work, a separate amplifier is mandatory. Fortunately, Yaesu has a matching 10-Watt linear amplifier available, the FL-2010. The amplifier is directly keyed by the FT-290 with a dc voltage carried on the antenna lead. It's a reasonably compact package and works well. Ten Watts should be adequate for FM operation, but serious SSB operators may want a little more power.



Top view of the FT-290.



Bottom view of the FT-290.

In Use

The human engineering factors are excellent by any standard. In this respect, the FT-290 is Yaesu's best product yet. For example, the priority channel is not just a single channel—you can choose one of any of the ten memories. Dial up a frequency on the main vfo knob, select one of the memories, and punch the priority switch. A beep will confirm that the switch was activated, and a "P" will appear briefly on the display to let you know that you're in the priority mode. Every few seconds, the priority channel will be checked for activity. If there is activity, the 290 will lock onto that frequency and remain there. Neat! This isn't the only well-thought-out feature. Almost every control and feature appears to have received a great deal of thought. The only inconvenience I encountered was the location of the switch that selects scanning for a busy or open frequency. It's located inside the battery compartment, which means that you had best plan on not changing it too often.

Transmit audio is good in both SSB and FM. I listened on a Kenwood TR-9000 while another staff member transmitted on the 290 and heard no problems. Received audio isn't quite as good as I've come to expect; the frequency response is narrow and the audio has a slightly muffled quality. This is considerably improved with an external speaker.

Conclusions

The FT-290's versatility is a powerful argument in its favor. New Hampshire has no lack of mountains to climb, and once stuffed in its rugged case, this transceiver is a worthy companion on any outing. The only other rig available that comes close is the Icom portable SSB rig, but it lacks FM capability and the sophisticated features of the 290.

Aside from versatility, the FT-290 gets high marks in performance and human engineering. If this rig is any indication, we can expect to see great things from Yaesu in the not-too-distant future. THE TELTONE M-929 —UN-TOUCHY TONE DECODING

During the nearly 9 years I have been working with repeater autopatches and other touchtone™-operated systems, I have tested and compiled information on a great number of touchtone decoders.

Recently, after spending much time trying to cure the voice falsing problems associated with one type of digital decoder, I ran across an ad for the Teltone M-927 decoder in a trade magazine. They advertised it as the system that "beat Dr. Glitch." Wow, did that catch my eye! The ad had barely come to rest on the top of my desk before I had called the company and ordered one. Normally, I am very skeptical of all-on-one-chip decoders. Because of the rigorous demands of radiotelephone operation, most decoders usually require some adjustments via external circuitry to make them work properly in a radio system. All-on-one-chip systems often lack the access needed to make these adjustments. Not so with this decoder. In fact, this decoder is so flexible and works so well that I had to let my fellow touchtone sufferers know about it.

The M-927 decoder is a complete system contained in a single 40-pin dip package. The only external component needed is a 3.58-MHz color burst crystal. The bandsplitter filters and wave-shaping circuitry, major headaches in other systems, are all included on one of the two LSI chips in the M-927 package. Furthermore, since the audio inputs to the differential amplifier are designed to attach directly to the telephone lines, they are internally capacitively coupled and capable of with-

Table 1. Output formats.

standing differential voltages up to 1500 volts. For single input operation, no biasing components are needed. Figs. 1(a) and 1(b) show the decoder block diagram and pinout.

In addition to the touchtone decoding portion of the circuit, Teletone makes provision for dial pulse input as well.The circuit is capable of accepting either touchtones, dial pulses, or both. A couple of enable lines (DT1, RD1) enable the user to selectively inhibit either type of operation.

Data is output from the decoder in one of four selectable formats shown in Table 1. Format 3 is interesting in that when it is selected both binary and 2-of-8 codes are available simultaneously. The blank output format can be used to clear the output latches in applications where momentary output coincident with signal presence is required. In addition to numerical outputs and several testpoints, clock outputs of three different frequencies are available along with a strobe line and a power-on-reset line.

Putting the Decoder to Work

Two weeks after placing the order, I received the decoder. I immediately put it in the circuit shown in Photo A and schematically depicted in Fig. 2. The components before and after the decoder are not absolutely necessary, but I have learned that when lightning strikes it is nice to have buffers between expensive parts and the outside world! The display is convenient for reading the decoder output.

The 741 op amp routes audio from either the main or auxiliary receivers to the decoder audio input in addition to acting as a lightning buffer.

The CD4515 decodes the M-927's binary output into 16 separate outputs which are then inverted and buffered by the CD4049 ICs. The strobe pulse from the M-927 is inverted and delayed by an RC network and a 74C14 Schmitt trigger inverter before being fed to the enable line of the CD4515 decoder. An additional RC network and inverter further delay the strobe pulse before it is output from the tone-decoder board. These delays ensure that *both the rising and falling edges* of the strobe pulse occur while the data is available at the outputs of the CD4049 inverter/buffers.

Since the M-927's strobe line is connected to the enable line of the CD4515, data is only output from the board while the tone is actually present.

Lastly, the CD4511 display decoder transforms the M-927's binary output to seven-segment form and directly drives a seven-segment common cathode display providing a visual indication of tone-decoder operation.

A lot of decoding on one board, isn't it?

One unrelated aspect of the schematic I'd like to point out is the 15-volt, 1-Watt zener across the power supply inputs. This lit-

tie device has saved many expensive ICs in the past by shorting out and burning the power trace right off the board when a voltage regulator went awry or when a lightning bolt hit. It is well worth its insignificant cost.

The Acid Test

Despite the impressive specifications of many touchtone decoders, they often bite the dust when faced with the acid test—amateur repeater operation.

Not this decoder! The M-927 took charge. It stubbornly refused to false decode despite the efforts of our best touchtone imitators. It ignored all manner of squawks and squeals. When it came to touchtones, though, the M-927 really came through. I couldn't hit the buttons on my TT pad fast enough to escape decoding. Even the fastest automatic dialers weren't fast enough to go undecoded!

During the several months that the M-927 has been installed in our system, it *has* voice falsed, but only twice. Not bad considering the many hours of voice, squelch noise, squawks, and squeals to which it has had to listen!

Rather than leave you with the thought that the M-927 is the perfect touchtone decoder, which it very nearly is, I must point out a few of its shortcomings as well.

The first and worst deficiency noted during several months of repeater operation was the M-927's relatively high signal-to-noise ratio requirement of 25 dB. In repeater terms, this means that the M-927 will not pick a weak signal out of the noise. In practice, we found that if a signal was too noisy for autopatch, it was also too noisy to bring it up. This turned out not to be such a bad shortcoming after all! If you need weak signal capability, Teltone was thinking of you when they created the M-927's big brother, the M-937. It is shown in Photo B. The M-937 has the same features as the M-927 with a signal-to-noise ratio requirement of only 10-15 dB. Although I haven't tested it, Teltone claims that the M-937 *will* pick signals out of the noise. A side-by-side comparision of specifications of the M-927 and M-937 is shown in Table 2.

A second deficiency, shared by all types of decoders, is temperature range. The M-927 will operate over the range of 0° C to 70° C. The M-927 can stand the heat of summer, but on cold winter days you'll need to keep it above the freezing mark.

Every weekend our repeater is remotely (via touchtone) switched to standby battery power. During one such weekend I discovered the M-927's third minor flaw—limited voltage range. Although all of our repeater control circuits are CMOS and are capable of operating down to 3 or 4 volts, the M-927 quits working when its supply voltage goes below about 11 volts. According to the data sheet, the M-927's operating voltage range is 11 to 13.5 volts. Believe it! I nearly had to take the long hike up the mountain to reset the repeater, but luckily after a short period of inactivity the battery recovered to a voltage sufficient to let the M-927 accept my reset command. For battery operation, therefore, I would recommend some type of 12-volt backup supply just for the decode itself.

No other shortcomings were found during three months of

operation in our repeater system. I am well pleased with the M-927's operation in our repeater and hope that this untouchy tone decoder will alleviate your touchtone headaches as well.

The M-927 is currently available directly from Teltone for $75 in single quantities, while the M-937 is priced at $131.

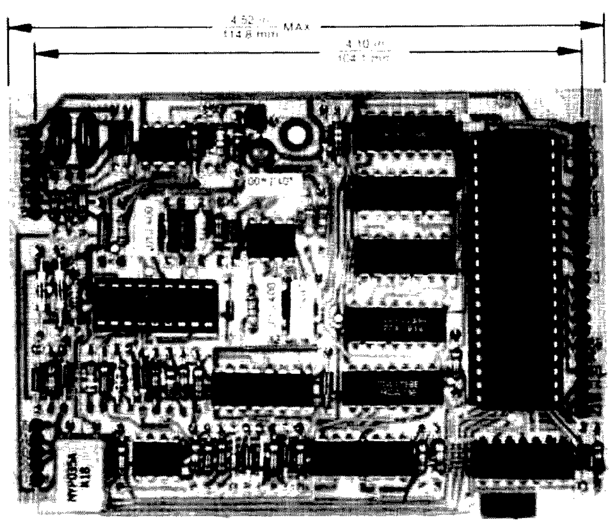

Photo B. The M-937 touchtone decoder.

At this writing, Teltone is preparing to announce the M-947, which is a stripped down M-927. The M-947 will have the front-end filters and tone-decoding circuits, but will not have the dial pulse circuits. It will have binary outputs only and come in a 22-pin package. Projected price will be in the $25-$30 range in single quantities.

For more information or a copy of my reference, the M-927 DTMF Receiver Data Sheet (Copyright 1980), contact *Teltone Corporation, PO Box 657, 10801-120th Avenue, Kirkland WA 98033; phone (206)-827-9626.* Reader Service number 476.

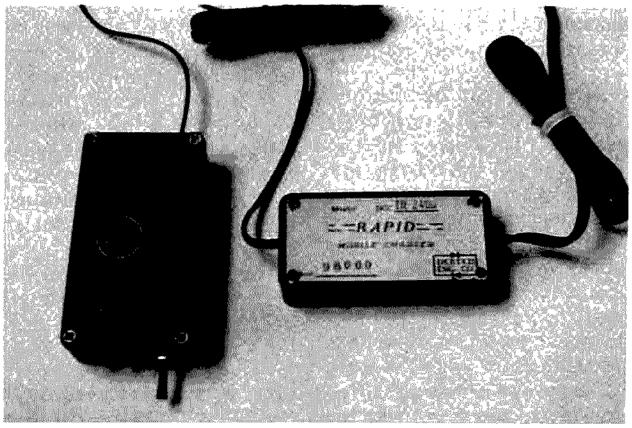
CHARGE IT! —REPORT ON MODELS FROM DEBCO AND INDIANA QUICK CHARGE

Find something that people want and fill the demand. That is how fortunes are made. The demand for a better way to charge nicad batteries came about shortly after synthesized handie-talkies arrived on the amateur market. Frustrated by the slow charging rate of the simple plug-in adaptors and horrified by the lack of availability and high prices for the official accessory chargers, hams learned to roll their own and before long several enterprising fellows started selling them. I don't know if they have made a fortune yet, but firms like Debco Electronics and Indiana Quick Charge are out to meet the demand.

Testing chargers can be a bit frightening since you are trusting your expensive radio to a power supply designed by someone other than the manufacturer. Most of the synthesized rigs are designed to operate in a tight voltage range. Kenwood's TR-2400, for instance, can be damaged if the input level exceeds 10 volts. Both of the chargers reviewed contained some sort of voltage regulation, but the similarities end there.

Debco's model, the Deb-Ted Rapid Mobile Charger, is designed to act as a go-between between the car cigarette lighter and the rig's battery charger socket. A small plastic box holds a circuit board that features a 723 regulator chip plus one other IC and four transistors. The result is a constant voltage charger that will bring your batteries up to full capacity in about five hours. As the batteries reach capacity, the current level falls off, preventing the harm that may result from overcharging.

Like the Debco unit, Indiana Quick Charge's QC-500 features talk-while-you-charge operation. The QC-500 circuitry is centered around a garden variety LM340 voltage regulator. The design includes two fuses and a hefty filter capacitor. Unlike the Deb-Ted, which is a plug-it-in-and-forget-it device, the Indiana Quick Charge unit gives the operator a switch to select between on and off, and there are three LEDs that indicate the presence of input voltage, a



The Debco Deb-Ted Rapid Mobile Charger and the Indiana Quick Charge QC-500 charger.

short circuit on the output, and the normal output condition. A die-cast aluminum case compliments the QC-500's clean, professional layout.

The QC-500 has proven to be a flexible accessory; it can be powered by either a 12-volt lighter or via a wall adaptor transformer. Debco has chosen to offer separate models, one for 12-volt use, the other for 110 V ac. Each company's charger will bring a discharged battery back to life in far less time than the conventional overnight chargers. However, many of the HTs in use today contain batteries that were not specifically intended for these faster energy transfer rates. Luckily, nicads tend to be forgiving and there were no obvious side effects resulting from the use of "quick" or "rapid" chargers.

One problem that plagues an owner of either charger is nonconventional wiring of an automobile's cigarette lighter socket. If you own a late model car and your charger doesn't seem to work, check the polarity of the socket. Normally, the tip is positive and the outer contact goes to ground. Both the Debco and Indiana Quick Charge units have diode protection in case the voltage is reversed. Correcting the problem involves reversing the leads at the socket or inside the charger case since the plugs cannot be disassembled.

Although our tests used a TR-2400, Debco and Indiana Quick Charge chargers are available for most of the other popular synthesized rigs. You can adjust the internal potentiometer if you need a different voltage rating. Don't fall into the trap of trying to use a line straight from 12 volts to your radio. You'll probably end up with a fried radio and an expensive repair bill.

Both chargers have a lot to offer. I liked the QC-500's classy appearance and flexibility, but I was also impressed by the Deb-Ted's sophisticated circuitry. Perhaps the two firms could get together and produce a super charger.

For more information, contact the manufacturers: *Debco Electronics, PO Box 9169 Dept. C, Cincinnati OH 45209,* Reader Service number 479; *Indiana Quick Charge, 367 West Main St., Danville IN 46122,* Reader Service number 480.

THE MICROWAVE MODULES MORSE TALKER —AN INFINITELY PATIENT TEACHER

Ah, the great stumbling block: learning the Morse code. Everyone looks for the easy way out, and manufacturers have been quick to provide all sorts of tapes, records, books, and flash cards to help out the would-be ham. With all these devices aimed at teaching the language of dah-di-dah, it takes quite an unusual approach to merit a second glance.

The Morse Talker, manufactured by Microwave Modules and imported by Spectrum International, is unusual enough to be worth not only a second, but even a third glance from both teachers and learners of the code.

The Talker is a small black box with an imposing number of switches and LEDs on its front panel. It generates Morse characters in random order. That's not so unusual, you say. Lots of modern keyers will send random Morse. Ah, but how many of them actually *talk* to you?

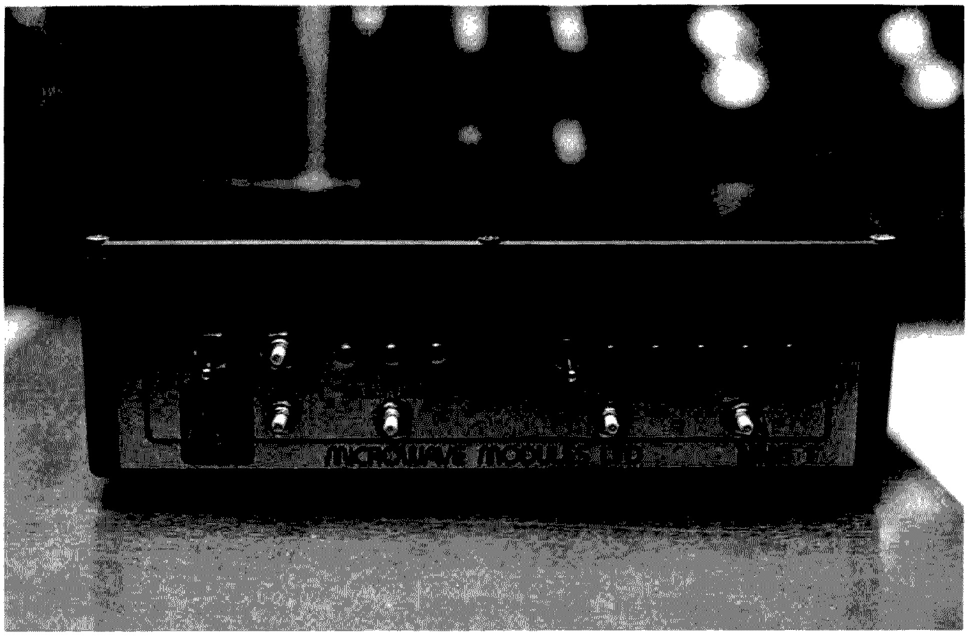
The secret of the Morse Talker is a voice synthesizer that tells you, after one, five, or fifty characters have been sent, what those characters were. It's quite impressive to hear this small device send fifty letters and numbers and then, in a voice right out of Star Wars, read them back to you.

You get instant feedback and, more importantly, in the single-letter mode the Morse Talker helps you associate a Morse rhythm with the letter it represents without the need of any visual crutch that will have to be discarded later. The learning process depends totally upon sound, and in theory this should make learning the code an easier task and make speed increases less painful.

Speeds from 2 to 20 words per minute can be selected. At the lower speeds, the code is sent at 12 wpm and spaced out enough to achieve the desired speed. An optional IC can be plugged in to set a speed range of 12 to 48 wpm. The Morse Talker can be programmed to send the entire alphabet and figures, or segments of the alphabet, with each segment adding new letters to the previous one.

The Morse Talker is enclosed in a die-cast box and all components are mounted on two double-sided glass-epoxy circuit boards, one of which contains a microprocessor that generates the code and tells the synthesizer what to say. The code generator program is contained in a 2716 EPROM. The second board contains a Digitalker voice synthesizer with its own microprocessor and memory.

The unit contains a small built-in speaker which provides adequate volume for a small room, or an external speaker or



The Microwave Modules Morse Talker.

amplifier can be plugged into a jack on the rear panel. There is also provision for operation as a code practice oscillator by connecting a straight key. A 12-V power supply is required for operation. One failure of the design is the lack of a power on/off switch or accessible volume control (the volume is only adjustable internally).

The only real disadvantage of the Morse Talker is its expense—not too many prospective Novices are going to be able to rush out and buy one, although the price should be in reach of most clubs sponsoring license courses. Aside from its price, the Morse Talker offers several advantages that make it a very useful training aid.

First, the biggest problem with tapes and records—memorization—is eliminated by the random generation of characters. Second, many users will find using the individual letter mode a very effective way to learn the code. Third, a "test" of 5 or 50 characters sent before reading back the answers provides a useful measuring stick.

We haven't had the opportunity to give the Morse Talker a real, total-beginner-to-licensed-ham test, but one student who had a chance to use it along with her other code-learning aids (including one each of just about every tape and record made) found it to be the single most useful part of her repertoire. She set up the machine to send individual letters at about 12 wpm and concentrated on connecting the sound with the letter. A half hour a day with the Morse Talker resulted in learning the characters quite rapidly.

In the end, though, whether you use the Morse Talker or a key and buzzer is not as important as whether or not you are willing to spend some time and effort on learning the code.

For further information, contact *Spectrum International, Inc., Box 1084S, Concord MA 01742*. Reader Service number 478.

FCC

USE OF ADDITIONAL DIGITAL CODES BY AMATEURS PROPOSED (Docket No. 20777 and PR Docket No. 81-699)

In response to a rulemaking petition by the American Radio Relay League (ARRL), the Commission is proposing to amend Part 97 of its rules to permit the use of new and experimental digital processes by amateur radio operators.

Currently, the only digital codes authorized for amateur use are ASCII (American Standard Code for Information Interchange) and the Baudot code. Such limitations may be discouraging the kind of innovation in the Amateur Radio Service the Commission has explicitly sought to encourage. For example, in 1976 the FCC began a rulemaking in Docket 20777 to deregulate amateur radio by eliminating emission-type restrictions. Because of comments filed in that proceeding, the Commission decided not to relax emission requirements but did authorize amateurs to use the ASCII code.

Because Docket 20777 is dated, the Commission is terminating that proceeding and associating the ARRL's request with a new digital coding proceeding.

The FCC proposes authorizing the use of any digital code in the transmission of amateur radio communications on frequencies above 50 MHz for domestic communications only. The frequency limitation is intended to protect operations in other countries from possible interference from the transmission of nonstandard codes.

Stations would still be required to identify themselves using conventional voice or telegraphy and would be required to maintain a record of the codes used and provide that record to the Commission on request. At any time, the Commission could restrict or prohibit the use of codes other than ASCII or Baudot by certain stations. These provisions are intended for monitoring and enforcement purposes.

The Commission further proposes to authorize an additional emission mode for ASCII in certain bands, increase ASCII sending speeds in certain bands, and clarify requirements by replacing the term "baud" with "bits per second."

In a related matter, the Commission denied a rulemaking petition requesting amendment of Part 97 by replacing the table of authorized emission types with a table of authorized bandwidths. This petition is being dismissed because it is inconsistent with the Commission's findings in Docket 20777.

Action by the Commission October 1, 1981, by Fourth Report and Order and Notice of Proposed Rulemaking (FCC 81-458 and 81-459). Commissioners Fowler (Chairman), Quello, Washburn, Fogarty, Jones, Dawson, and Rivera.

For more information contact Steve Lett at (202)-632-7597.

HAM HELP

I would appreciate hearing from anyone who has made any type of modifications to a HAL DS-2000/ST-5000 RTTY system. Mods of special interest are additions of computer-type line printers such as an Epson MX80-FT or the like. I am currently using an old Kleinschmidt 60-wpm machine, but that is no good for the other baud rates and ASCII. I do have a TRS-80 Model III, but would rather use the dedicated HAL system for RTTY. Anybody have any ideas?

Stan Gantz WB5TGL
PO Box 2820
Silver City NM 88062

Help! I need service manuals for the following obsolete FM equipment:

- G.E. "Pre-Prog" mobile, Model 4ES12A3;
- Ac "Spark Plug," Model CVT-1 (WE-15996), a.k.a. Delco Acheiverfone;
- Utica Communications Model "Uticom";
- G.E. "Prog-Line" base station, no model number, housed in a cabinet about the size of a 2-drawer filing cabinet, 25-30 MHz, Tx P.S. numbers 4EP4A1, 4EP4A2; Tx #4ET23A1; Rx P.S. #4EP3A1; RX #4ER24A1.

I also need (dead or alive) a Motorola # NPN 6013A ac supply, or a # NPN 6011 6-/12-V/ nicad supply. These were used with the old hybrid P-31/33 series of handle-talkies.

Barry Fuerst
218 Flournoy St.
Oak Park IL 60304

I am the owner of a Yaesu FT-207-R 2-meter HT. The frequency coverage is from 144 to 148 MHz. I would like to extend this range to cover MARS. I have seen articles on the IC-2A which changed its coverage from 144-148 to 140-149.9955.

This is the type of modification I would like to make to my 207-R. Any information on this mod would be greatly appreciated.

Willard Brown WB3GNN
350 Orchard St.
Old Forge PA 18518

I am looking for other ham radio operators who are owners of Atari computers for the purpose of starting a National Atari Net. This net would meet once a week on a given frequency and would enable us to exchange information and ideas concerning Atari computers.

Sheldon Leemon N8SL
14400 Elm Street
Oak Park MI 48237

I need service information on a WWII piece of equipment made under contract for the US Government. It is an RBM-5, type CAY 46077-A high-frequency receiver made by Westinghouse on contract NX57-38081 in 1942/43. I wrote Westinghouse, but they can't help.

OSCAR ORBITS

Despite a troubled infancy, amateur radio's newest satellite, UoSAT-OSCAR 9, was alive and well as this issue of *73* went to the printer.

After a perfect launch on October 5, the first signal heard coming from the satellite was a strong carrier with only a small amount of garbled modulation instead of the expected 1200-baud ASCII telemetry. It was five days before the spacecraft was successfully directed into a 300-baud mode, giving the world a chance to obtain and digest information about the satellite's well-being.

Early data indicated that a problem existed with two of the three navigation magnetometers. Experts associated this with the colder than expected spacecraft temperature. Before any experiments can be conducted, the satellite must be stabilized, an operation that is dependent on knowing the bird's attitude and spin. Without the proper "nav mag" data, a new operational plan must be formulated. It was expected to take four to six weeks to gain full control of the situation.

Satellite enthusiasts report that OSCAR 9's 145.825-MHz beacon can be heard with a rubber-duck-equipped handie-talkie. By using a 5/8-wave or better antenna, it is possible to get a full quieting signal with an ordinary two-meter receiver. The orbital data that was available for OSCAR 9 in early October is:

- Period: 95 minutes, 28.796 seconds
- Perigee height: 533 km (331.21 mi.)
- Longitude increment: 23.86563 degrees west
- Apogee height: 536 km (333.07 mi.)

The orbital listing given below is based on this data. Since OSCAR 9 has a very short track record, the accuracy of the listing may not be as great as it would be with an established satellite.

This article is based on material from the *AMSAT SATELLITE REPORT*. For more information on the amateur space program, contact: AMSAT, PO Box 27, Washington DC 20044.

south of Glasgow on Highway 31E. Admission is $2.00 per person with no extra charge for exhibitors. One free table will be provided per exhibitor with extra tables available at $3.00 each. There will be a large heated building with plenty of free parking. No meetings or forums will be held—just door prizes, free coffee, and a large flea market. Talk-in on 146.34/.94 or 147.63/.03. For additional information, contact Bernie Schwitzgebel WA4JZO, 121 Adairland Ct., Glasgow KY 42141.

LIVONIA MI
FEB 28

The Livonia Amateur Radio Club will hold its 12th annual LARC Swap 'n Shop on Sunday, February 28, 1982, from 8:00 am to 4:00 pm at Churchill High School, Livonia MI. There will be plenty of tables, door prizes, refreshments, and free parking. Talk-in on 146.52. Reserved table space of 12-foot minimum is available. For further information, send an SASE (4 × 9) to Neil Coffin WA8GWL, c/o Livonia Amateur Radio Club, PO Box 2111, Livonia MI 48151.

MIDLAND TX
MAR 13-14

The Midland Amateur Radio Club will hold its annual swapfest on Saturday, March 13, 1982, from 8:00 am until 6:00 pm, and on Sunday, March 14, from 8:00 am until 3:00 pm, at the Midland County Exhibit Building east of Midland TX on the north side of Highway 80. Registration is $5.00 in advance or $6.00 at the door. An additional $3.00 will be charged for each table. There will be door prizes. Talk-in on 146.16/146.76 and 146.01/146.61. For more information, write the Midland Amateur Radio Club, Box 4401, Midland TX 79704.

WINCHESTER IN
MAR 14

The Randolph Amateur Radio Association will hold its 3rd annual hamfest on Sunday, March 14, 1982, from 8:00 am to 5:00 pm at the National Guard Armory, Winchester IN. Tickets are $2.00 in advance and $3.00 at the door. Table space is $2.50 and table space with table is $5.00. Setup times are 6:00 pm to 8:00 pm on Saturday and 6:00 am to 8:00 am on Sunday. For reservations or additional information, contact RARA, PO Box 203, Winchester IN, or phone W9VJX at (317)-584-9361.

HAM HELP

We are happy to provide Ham Help listings free, on a space-available basis. We are not happy when we have to take time away from other duties to decipher cryptic notes scrawled illegibly on dog-eared post cards and odd-sized scraps of paper. Please type or print (neatly!), double spaced, your request on an 8½" × 11" sheet of paper and use upper- and lowercase letters where appropriate. Also, please make a "1" look like a "1," not an "l," which could be an "el" or an "eye," and so on. Hard as it may be to believe, we are not familiar with every piece of equipment manufactured on Earth for the last 50 years! Thanks for your cooperation.

Wanted: work in the electronics field in the Knoxville/Chattanooga area. Experience in digital and rf circuits. I have First Class radiotelephone and Extra class amateur licenses.

Herman F. Schnur
115 Intercept Ave.
North Charleston SC 29405

I need an instruction manual and/or schematic for a model CF capacitor analyzer (Exam-Eter) made by Solar Mfg. Corp., New York. Please write and let me know what you have.

G.V. Mock W4RHD
Rt. 1, Box 60
Fayetteville AR 72701

Wanted: any information on conversion of Cobra 21XLR to 10-meter FM. Uses Uniden PC-199AB board with crystals for 10.24, 10.695, and 36.57 MHz. Has anyone converted this rig? Help!

Al Graff N8CNB
PO Box 332
South Webster OH 45682

I need a schematic and/or manual for an Advance Instruments oscilloscope model OS 15A (sometimes called Xetex). I will copy and return. All your costs gladly paid.

Walter S. Jackson KB3LH
281 Irish Road
Berwyn PA 19312

I have the schematic for my WWII-vintage Hammarlund type CHC 46140 receiver, but no values of components are given. Can anyone supply further data on this radio?

H. Church
309 W. St. Louis St.
Lebanon IL 62254

I need a schematic or a manual on a Central Electronics multi-phase exciter, Model 10B, and Model 458 vfo. I will copy and pay all postage.

Louis Sila WB6FRQ
1085 W. 27th St.
San Bernardino CA 92405

Recently, someone wanted info on war surplus from the '40-'45 era. I had this info and was glad to supply it. My request was to have the postage paid.

I neither got the postage *nor a* thank-you. You could remind the people requesting such info that a thank-you is appreciated. It will be a cold, frosty day before I comply with another request. Since the last time, I have seen quite a few inserts I could help, but once stung, twice shy.

Leon D. Tallman W1JTI/OY1KH
Star Route
South Effingham NH 03882

Am looking for a schematic or assembly manual for a model W5M amplifier. Also same for a model WAP2 preamplifier. These are both Heathkit units. Will copy and return, postage paid. Thank you.

F.N. Lockwood WA6UCP
910 Jack London Drive
Santa Rosa CA 95405

I urgently need a schematic or any service information on the Beltek model W5570 2-meter FM transceiver. The manufacturer in California is out of business. Thank you.

Rev. Ray Vath WB2FYB
PO Box 306
Ridgefield Park NJ 07660

I have a telephone-type (PBX) headset which I would like to hook up to my Kenwood TR-2400. Any info would be appreciated.

Roy Eichelberger KA7GXX
1136 Turquoise Way
Sandy UT 84070

I would like to obtain a manual or schematic for a Gonset Sixty-Three. Also, if anyone needs a Knight Star Roamer manual for his set, he can contact me.

Kevin Neal
Rte. A, Box 221A
Flippin AR 72634

I need a manual and schematic for a General Electric oscilloscope model CRO 5A. Will copy or pay for copy. Also need parts or a used Heathkit IT-11 or IT-28 Capacitor Checker. Thank you.

William P. Pence
800 Old Stage Road
Cave Junction OR 97523

Does anybody know the type of balun and the resistance and wattage of the resistor used in B&W's new folded dipole antenna? Any information concerning the above would be greatly appreciated.

Marvin Rosen N3BQA
20 W. Madison St
Baltimore MD 21201
(301)-685-8308

Needed for parts: a beyond-repair IO-10 Heath scope to complete a partial scope kit.

Rudy Zerdecki WB1CXC
PO Box 321
Indian Orchard MA 01151

I would like a manual and/or schematic for a Tektronic Type 504 oscilloscope. I will pay copying costs.

One thing that is very obvious and is becoming worse with more activity on the bands is the quality of SSB signals. SSB by its nature is so pure, clean, and lean. Theoretically, two or three stations can operate almost on the same frequency. There is no carrier to interfere as we had on AM. But . . . then came those #$%& speech compressors in the hands of operators who refuse to try to understand the technical side of things. I think it must be a carry-over from the "ten-four" band where the only thing you had to know was to keep that meter way up there, because that was when you were getting more "pounds" out. Wrong!!!

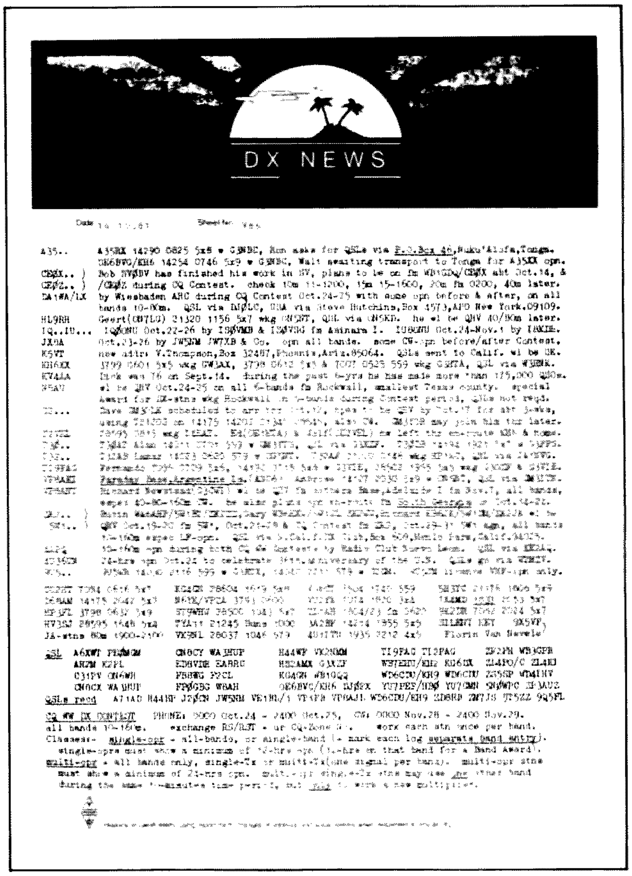
Speech processing has its value but it has to be understood. When a ham cranks that devilish instrument all the way up then he starts QRMing his own signal. One can hear the fans running, dogs fighting on the street, and even the stomach rumbling. All this is creating splatter that gives a very bad image of the ham and his station.

It is quite simple to adjust the gain just by observing the plate or rf meter on your transmitter or amplifier. When you press push-to-talk without saying anything, the meter should not move. If you are getting more deflection on the meter when you are not talking than when you are talking, then obviously it is a bit too much. Another situation is bad neutralization, which creates all kinds of spurious signals inside and outside the bands, including terrific TVI. Also watch for a wrong bias adjustment on your PA amplifier or transmitter. That could put your rig into Class C, and there you have another factor contributing to your beautiful signal.

Why all of this? Well, if you listen around you know why. The garbage level on the bands is very high. It doesn't take too many stations to wipe out the band and make it impossible for others to hear that XZ9A who is trying to call you.

The same goes for the DX pileups. Gone are the days when you could pick the callsigns out of the pile because they were clean and understandable. Three bad stations can wipe out half a band and make it difficult for the DX station to hear anyone.

We consider ourselves gentlemen, so let's do it right and be proud of our signals!



Typical Big Gun Contest (and DX) station of KØRF. Cement blocks and boards serve as an operating desk, not for the great looks but for the super-efficient layout of three rigs and all the other gadgets. Outside are three 200-foot towers with assorted high-performance antennas. Chuck KØRF (left) is discussing strategy with George WØUA before an upcoming contest. George is a frequent high scorer in sweepstakes and holds a number of records.

BULLETIN OF THE MONTH

This time we look at another weekly DX bulletin from across the pond. It is the continuation of the old and famous Geoff Watts bulletin, still edited by him, published by the RSGB, and called *DX News Sheet*. It is getting close to its 1000th issue. It lists activities and expected operations, has QSL information, and gives upcoming contest rules. The sample shows the arrangement.

DX NEWS

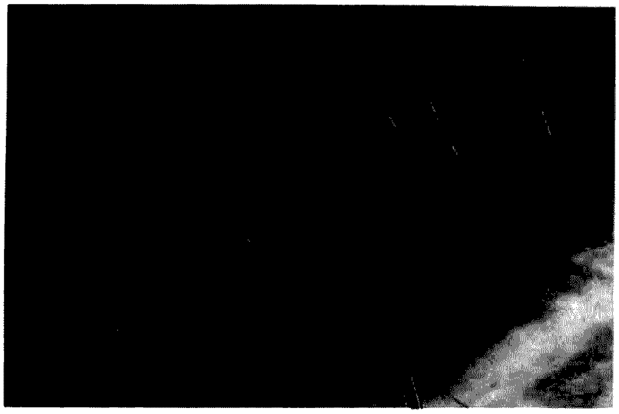
A6XJA, United Arab Emirates, showing up on 15m around 21.200. Operator is Jan-Keur; QSL via PAØLP or direct: PO Box 2730, Abu Dhabi, United Arab Emirates. A6XJC keeps occasional schedules with WB2OHD near 28.688 for short lists around 1500/1530 GMT. Claiming valid license and expects to be there for some time. QSL via PEØMGM.

A9XDO, Bahrain. Operator Howard showing up on 28.607 at 1545, 14.236 at 0200, 14.020 at 0345. QSL via KA4S. A9XDA, Paul, around 14.182 at 0200; QSL via N4BPP.

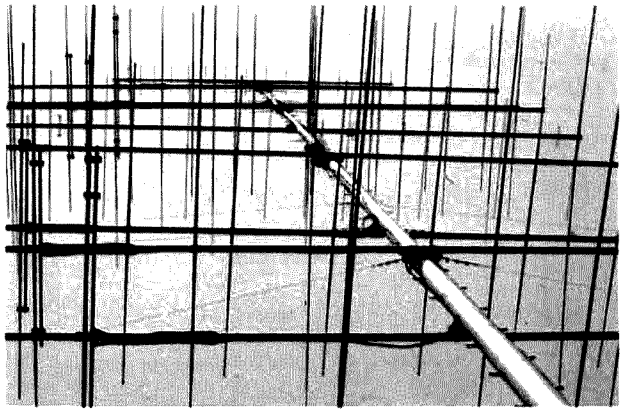
A22ZM, Botswana. Mark is now in South Africa; QSL via ZS5CU. A22VL will be on the air for about two years, operated by W9VL, showing up in the major contests and some DXpeditions.

BV2A, Taiwan. Tim is back on the air after the hurricane season. He takes the antennas down himself, rather than let Mother Nature do it. QSL direct.

CEØX, San Felix Island. Wow! Bob Read KF1O, ex-WB1GDQ, received his Extra class US license just in time for this historical operation. Both "partners," WØAX and N4CBL, have bowed out of the operation and Bob fired up from CEØX quite quickly. While some were figuring that it would take him a day or so by boat, he managed to get there by air and surprised the world by showing up on 15m for a few QSOs. Later he operated on 20 and 10m also. Apparently, there were only a few hours of



Ever wondered what hit you in the pileup? The answer is in the antennas. This is the VE3BMV Razor Beam, just going up on the top of the 110-foot rotatable pole. It has 4 quad elements (2 driven) and three yagi elements on a 60-foot boom. And there are two of them stacked. They really cut through the pileup and give the edge!



This one is at the "Papa Victor" antenna farm—the W2PV multi-multi station. Stacked Telrex beams on the 110-foot Big Bertha. The configuration reads, from top down: 6 elements on 20, 8 on 15, 10 on 10, 3 on 40, and, again, 10 on 10, 8 on 15 and 6 on 20. That surely gets respect on the band! So, the next time you can't hear the one they are working, don't worry about it (unless you have more elements up there).

operation his work permitted. The pileups were much worse than Clipperton has experienced. Poor list operators, they did not get the chance. Job well done, considering the restrictions that Bob was faced with. About 700 contacts were made, mostly with US stations. There is some chance he might be invited back and be able to do some more operating. QSL to his SVØBV address: Box 564, Athens, Greece.

FB8WG, Crozet Island. George is operating as much as his schedule is permitting him. He should be there for about 9 months. Usually showing up on the French net on 14.170 or 21.170 at 1800Z. Operating list on weekends around 21.279 from 1200Z. QSL via F2CL. Another one who operates with the help of the list "undertakers." Hoping to get the vfo and operate on his own.

FPØGBG, St. Pierre and Miquelon. Operation by Al W8AH. Also FPØGAP by W8NR, FPØGAO by K8CJQ. QSL to their home calls.

HS, Thailand. Thai radio amateurs are back on the air. Apparently they were off because they had to register their rigs. The same old callsigns are still assigned, so there is no change. Dr. George Collins VE3FXT is supposed to be back in HS for some more tests and demonstration of coherent CW, and is hoping to get on from XZ—Burma.

HV, Vatican and Radio Vaticana, is celebrating the 50th anniversary and offering an award for working several amateurs there. Stations in Europe and the USA must work two of the three stations, all others need work only one. The calls are HV3SJ, HV1CH, HV2VO. Starting date was October 1 and it runs until February 1, 1982. Send photocopy of QSL card to Radio Vaticana, Citta del Vaticano, Europe.

T3, Kiribati. The following are separate countries for the DXCC: T30—Western Kiribati (Gilbert or Ocean Island), ex-T3A or VR1; T31—Central Kiribati (British Phoenix Island), ex-T3P, VR1; T32—Eastern Kiribati (Christmas or Line Island), ex-T3L, VR3. Recently active: T32UF around 21025 at 0230; QSL via JA1NVG. T32AB around 21298 at 0300; QSL via N7YL.

V3A, Belize. This is the new prefix and not J9 as previously announced and expected. This should replace the old VP1 prefix in the callsigns. VP2A Antigua is expected soon to become V2A.

XZ, Burma or Karen State? According to JA8BMK and most people, these should be recognized as separate DXCC countries—that is, as XZ9A and XZ5A. There was some activity reported by other stations with XZ2 and XZ1 callsigns operating from Rangoon, Burma.

1AØKM, SMOM or Sovereign Military Order of Malta, was finally accepted by the ARRL as a separate country for DXCC. This brings the current total back to 319. They were supposed to be in the CQ WW contest but it was a no show. QSL cards are being accepted after January 1, 1982, for all the contacts made with 1AØKM.

3X1Z, Guinea was on again by Jacques W4LZZ on October 11-23. QSL via W4FRU.

5A7BQ, Libya. Operator Abed is active around 28546 at 1700 and claims to be a permanent resident with a valid license. QSL via Box 733, Benghazi, Libya.

5R8, Malagasy Republic, activated by Luigi IV3OSHN/5R8 between September 20-28; QSL via IV3MUC. 5R8AL is active around 28535 at 1730, QSL via WA4VDE.

7O1AB, South Yemen, could be on at any time. J28AZ is the holder of the license and it is supposed to be a matter of picking it up and operating. (We have been hearing about this for six months.)

AWARDS

Bill Gosney KE7C

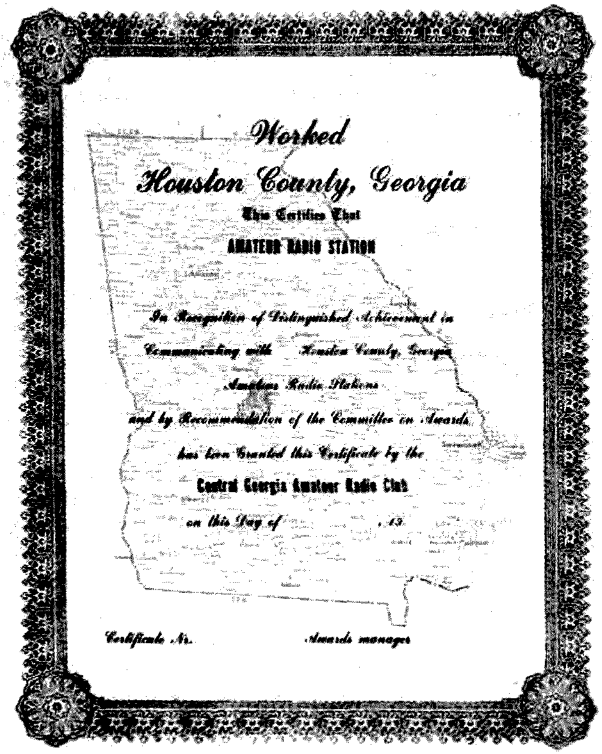
Oak Harbor WA 98277

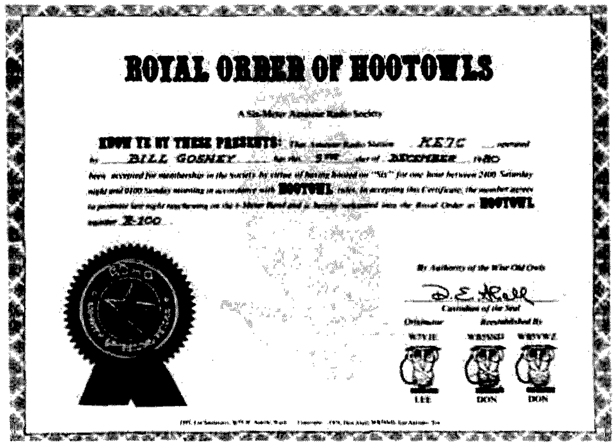
W2JIO NAMED AS 1980 ARMSTRONG PIONEER

Bob Gunderson W2JIO has been voted the first recipient of the annual Armstrong Memorial Award. It was given to him in recognition of his outstanding contributions to amateur radio via his work with and for blind hams. Bob, who was born blind himself, has designed and built many kinds of test instruments with audio outputs as well as other methods of working with electronics for the sightless. He also founded the Braille Technical Press, and taught electronics for 37 years at the New York School for the Blind, directing many students toward rewarding careers in electronics.

The award was presented at the 1980 ARRL Hudson Division Convention. Bob could not be present, so a tape recording of this event was sent to him along with the plaque.

The award, a sort of "Most Valuable Player" of amateur radio, honors the memory of Major Edwin Armstrong, inventor of frequency modulation and other technical advances which have benefitted amateur radio. It will be given each year to one ham for his or her outstanding service to the amateur community. Some of the nominees for 1981 are Copthorne MacDonald W4ZII, father of SSTV, Don Stoner W6TNS, driving force behind the original OSCAR program, and HRH Hussein, JY1,





for his help in promoting the concept of amateur radio throughout the Mideast. If you would like to nominate someone, just send a note to Awards Committee, Major Armstrong Memorial Amateur Radio Club, Box 1234, Englewood Cliffs NJ 07632.

SPECIAL EVENTS STATION FOR LEWIS AND CLARK WINTERING SITE

A Special Events station will be sponsored by the Mandan-Bismarck Amateur Radio Club on January 2 and 3, 1982. There will be a distinctive OSL card this year, featuring Sakakawea, the Indian maid who led the expedition to the West Coast.

Time of operation will be 1600-2100 UTC on both days. Frequencies to be used: SSB—14295, 21395, 28595; CW—14065, 21065, 28065; and Novice—21125, 28125. All frequencies plus-minus QRM.

To receive the special commemorative QSL card, send an SASE to the Mandan-Bismarck Amateur Radio Club, PO Box 978, Bismarck ND 58501. (For additional information, you may contact Ed Drewello WB0OFW at the same address, or call (701)-223-0150, Ext. 124.)

THE WORKED HOUSTON COUNTY GEORGIA AWARD

The Central Georgia Amateur Radio Club of Warner Robins, Georgia, is proud to announce the establishment of the Worked Houston County Georgia Award.

The requirements for obtaining this handsome, three-color award are:

- US stations are required to contact five (5) amateur stations in Houston County. Stations in Houston County need ten (10) contacts with other amateur stations in Houston County.
- DX stations are required to contact three (3) amateur stations in Houston County, Georgia.
- All contacts must be made on the 10-through-160-meter amateur bands. Endorsements for single band, single mode, etc., will be honored upon request.
- All contacts must have been made February 14, 1981, or later.
- The fee for this award is $1.00 plus two (2) first-class stamps for US stations. DX stations please send four (4) IRCs. Send fee and list of claimed contacts (no QSL cards) with complete log information to: Awards Manager, Manuel Matta WD4ENO, 619 American Boulevard, Warner Robins, GA 31093, USA.

ROYAL ORDER OF HOOTOWLS

The Royal Order of Hootowls became a society in June of 1955 with the "gag" nomination and hand-drawn owl being sent to John Woods W7TMI, after burning the midnight oil with the originator, Lee Singleterry, Sr. W7YJE. Dick W7VIC, Gordy W7UFE, and Tad W7WZK rounded out the charter membership, and the granddaddy of 50-MHz societies was born!

The Order became dormant with the passing of Lee, but in 1977, Don Abell WB5SND located Mrs. Singleterry and was granted permission to reestablish the Order once again. This was completed in 1978 in partnership with Don Verlander WB5VWZ.

The Order is not a net but a society founded to promote friendship and goodwill toward amateurs everywhere, and was developed to enhance and preserve activity on the late Saturday night 6-meter ragchew.

ROHO membership is open to any licensed amateur who meets the following conditions:

- All contacts must be made on the 6-meter band and must be point-to-point; contacts by relay are not valid.
- Call "CO Hootowls" on 50.200 at midnight (2400) local time on Saturday night only.
- Establish and maintain two-way contact with a member station for a minimum of one full hour starting at 2400 Saturday night and ending not earlier than 0100 Sunday morning. DX stations may qualify by making contact with an Owl at *any time* during the above stated period.
- To apply for the affiliation and membership certificate, submit the name, callsign, ROHO number of the member station worked, and the date worked, along with your own name, address, and callsign. There is a one-time membership fee of $2.00.

Make your check payable to Don Abell, 6821 West Avenue, San Antonio TX 78213.

ROMANTIC ROAD AWARD

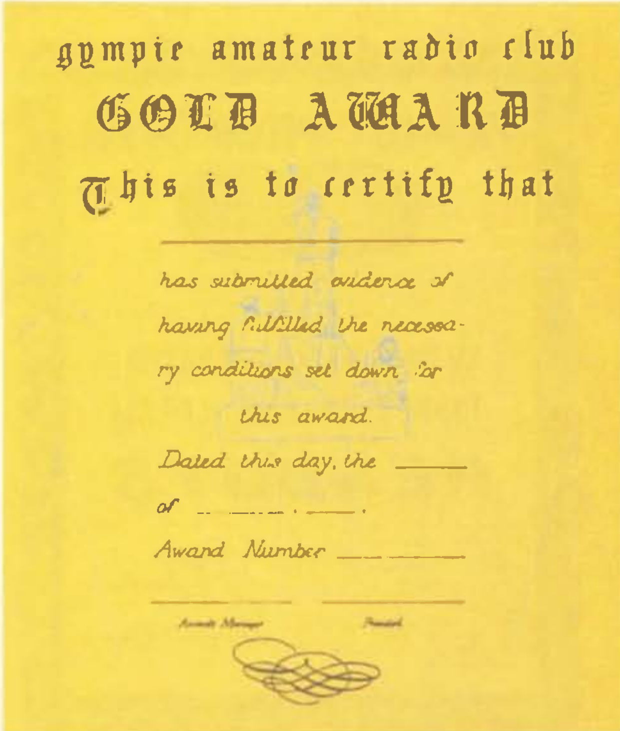
The local group (OV) Nordlingen of the German Amateur Radio Club issues this award on the occasion of its Jubilee (25th year) to all licensed radio amateurs and SWLs for contacts with stations along the "Romantic Road," located in Wurzburg, Tauberbischofsheim, Bad Mergentheim, Creglingen, Rothenburg o.d. Tauber, Feuchtwangen, Dinkelsbuhl, Nordlingen, Harburg, Donauworth, Augsburg, Landsberg, Schongau, Schwangau, and Fussen.

List of DOKs valid for the award: A 23; B 02, 17, 18, 22; C 20, 21; P 25; T 01, 06, 09, 11, 17, 21; Z 30, 52.

Requirements: Each QSO with stations along the Romantic Road will count 1 point, each CW QSO 2 points, and each RTTY QSO 3 points. Contacts with members of the "OV" Nordlingen, DOK T 09, count double points. European stations need 50 points, and VHF and DX stations need 25 points.

This certificate is also available to SWLs.

The fee: DM5, US$4, or 10 IRCs. Send to Friedl Schrey, PO Box 1, D-8855 Wemding, W. Germany.



WORKED ALL BOWIE AWARD

The Bowie Maryland Amateur Radio Club is offering the Worked All Bowie Award to amateurs who make contact with stations located in this Washington DC suburb.

The Bowie Award is issued in two classes: Class 1 for contacts with four stations located in the city and Class 2 for two contacts within Bowie. DX stations, to qualify, must work two Bowie amateurs for Class 1 recognition and work one station within Bowie for Class 2.

There is no fee for this award, but applicants are requested to accompany their log extracts with a large (#10) self-addressed stamped envelope. Forward your applications to: John Rouse KA3DBN, PO Drawer M, Bowie MD 20715.

GARRETT ISLAND AWARD

The Bowie, Maryland, ARC is still offering the Garrett Island Award to any amateurs who worked K3PI during the mini-DXpedition to this uninhabited island located near the Chesapeake Bay in Cecil County, Maryland. A second large SASE to John Rouse KA3DBN, PO Drawer M, Bowie MD 20175 will get you the award. By the way, QSL cards *are* required as proof of contact.

LINCOLN TRAIL AWARD

The Lincoln Trail Amateur Radio Club, Inc., will be holding an in-state DXpedition from Abraham Lincoln's birthplace in Hodgenville, Kentucky. Hodgenville is located in LaRue County.

The expedition will be on February 13 beginning at 0000 UTC. The station call will be NN4H. Planned frequencies are: Phone—15 kHz from bottom of the General phone band; CW—15 kHz from bottom of the General CW band; Novice—15 kHz down from top of band edge. For certificate, send an SASE to Charlie Myers, PO Box 723, Elizabethtown KY 42701.

FREEZE YOUR ARCTIC OFF CERTIFICATE

The Tin Lizzies are at it again! The fourth annual Freeze Your Arctic Off expedition will take place between 1700Z January 23 and 1800Z January 24, 1982, using a twenty-mile-wide frozen lake as the ground plane for our phased vertical array. As in the past, a handsome certificate will be sent to all QSLed contacts. No SASE is needed, but *please put your contact number on your card.*

Look for AD8R/8 on 7.275, 21.380, 146.55, and 146.58 MHz out on the frozen wastes of Lake Saint Clair near the US-Canadian border. QSL to Box 545, Sterling Heights MI 48077-0545.

ROBBINSDALE ARC OPERATION ICEBOX

The Robbinsdale Amateur Radio club (KØLTC) is proud to announce its second Annual Operation Icebox from the frozen surface of Rainy Lake, near International Falls, Minnesota. Operation will begin on February 5, 1982, at 0000 GMT and run till February 6, 1982, at 0000 GMT. The frequencies used will be 10 kHz up from the bottom of the General Phone bands. Novice operation also is planned. There will be two operating stations to cover 80m through 10m. KØLTC is offering an attractive 8½ × 11 commemorative QSL of the event to all who enclose an SASE (business size) with their card. The QSL route is via KBØPM, club president.

GYMPIE AMATEUR RADIO GOLD AWARD

The Gold Award is open to all licensed amateur radio stations and shortwave listeners. Stations must obtain ten (10) points by working Gympie Amateur Radio Club members. Overseas stations need obtain only five (5) points for qualification.

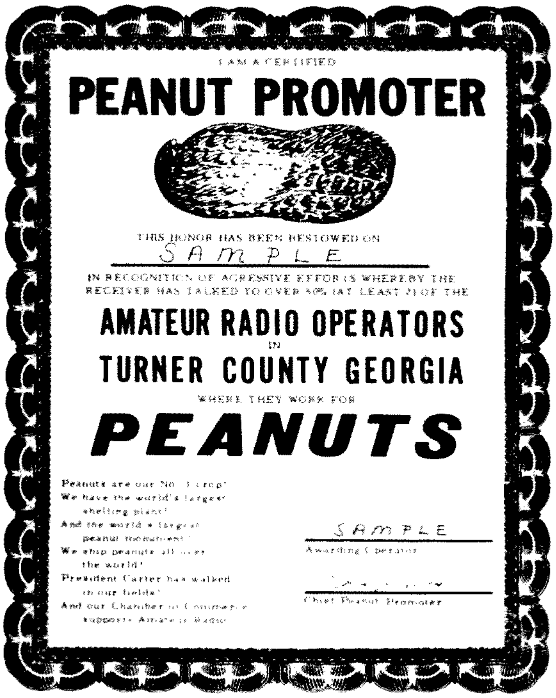
Stations can be worked on any band using any mode. Active modes are: SSB, CW, FM, AM, and RTTY. Contacts on HF count as one (1) point each. Contacts on VHF (52 MHz and up) are worth two (2) points each. A contact with the club station (VK4WIH) counts as two (2) points on any band. Contacts via repeaters are not valid.

Stations can be worked once on each band. QSL cards are not required. Applicants must send a log extract containing all relevant information (date, time, frequency, mode, signal report, callsign). Contacts after October 13, 1980, are valid.

Domestic cost of the award is $1.00 or three IRCs. Overseas stations: $2.00 or five (5) IRCs. Address the Awards Manager, Gympie Amateur Radio Club, PO Box 384, Gympie, Qld., 4570, Australia.

PEANUT PROMOTER AWARD

This award is sponsored by the Turner County Chamber of



Commerce in conjunction with the Coastal Plains Amateur Radio Club based in Ashburn, Georgia.

To qualify for this award, an applicant must work at least two stations in Turner County, Georgia. Both QSL cards received from these contacts must be sent to the Awards Manager along with an SASE.

Actually, the club has two managers for this award. If your contact was made on six meters, then forward your application to: "Fuz" Tanner WA4NTF, Route 2, Box 351, Ashburn GA 31714. If your contacts were made on any other band, send your application to Wayne Harrell WD4LYV, Route 1, Box 185, Sycamore GA 31790.

I am not sure if there is a fee for this award—the award rules failed to mention any remittance. To be safe, however, I would enclose a minimum of $2.00 to cover the club's expenses.

VERNON BC WINTER CARNIVAL CERTIFICATE

We of the North Okanagan Radio Amateur Club (NORAC), along with the Vernon Winter Carnival Society, are sponsoring a certificate this year to celebrate the 22nd Annual Vernon Winter Carnival, western Canada's largest winter carnival, held annually in February. This year the carnival is being held February 5-14.

We will be operating daily from 2100-2400 Zulu, and on February 7 from 2000-0200Z. This is a free award, and all you need to do is send the log information of QSOs with three (3) Vernon area stations or one contact with the club station (VE7NOR) to PO Box 1706, Vernon BC V1T 8C3. (Vernon area is defined as Armstrong, Enderby, Oyama, Winfield, Lumby, and Vernon.) Frequencies to watch are: 28.575, 21.375, and 14.295 plus or minus QRM, with possible CW and RTTY operation also.

The award is available year-round; all QSOs are valid.

CQ CQ CQ . . . HIGH SCHOOL AND COLLEGE CLUB STATIONS

The McKinley High School Amateur Radio Station (KH6NF) is trying to make contact with teenagers and young adults around the world. McKinley High is the oldest public high school in the state of Hawaii, being 116 years old this school year. We are located in Honolulu, just minutes away from the famous Diamond Head crater and Waikiki Beach. Our student population is just over 2000, and it rivals the United Nations with our diversity of cultural and national heritages.

The club station has been in operation since 1966, but this year we are making a special effort to contact other club stations and younger members of the amateur radio society. We are inviting everyone to join us on the bands and make this year an outstanding one for youthful hams.

Our hours of operation will be from 1730Z to 1815Z and 0045Z to 0115Z Monday through Friday, and 2000Z to 2130Z Monday, Wednesday, and Friday. At present, we operate on 10 meters, 28.520 MHz ± QRM. If 10 meters closes up, we will operate 21.420 MHz or 14.320 MHz.

If you are unable to contact us because of poor band conditions, please drop a line to set up a schedule and we will do our best to have a QSO with you. Our address is McKinley High School Amateur Radio Station, 1039 S. King Street, Honolulu HI 96814. Until we meet you on the air . . . Aloha!

WORKED ALL HAWAII AWARDS

Sponsored by the Big Island Amateur Radio Club, these awards are available to all licensed amateurs. Contacts made after 0000Z January 1, 1982, are valid for the awards.

Any mode on any band is acceptable. No terrestrial repeater contacts will be accepted, and only land-based stations are valid for the awards.

Do not send QSL cards. A list showing the date, time, signal report, mode, callsign, and band, certified by a club or society official, is sufficient.

The fee for any award is US $3.50; three awards are available: Class A—Wood-carved tiki (certificate only for stations located in the State of Hawaii); Class B—Certificate; and Class C—Certificate.

Class A requirements: Work 100 Hawaiian stations, to include (A) the islands of Hawaii, Maui, Lanai, Molokai, Oahu, and Kauai; (B) the counties of Hawaii, Maui, Kalawao, Honolulu, and Kauai; (C) one of the following islands: Kure, Midway, Necker, Laysan, French Frigate Shoals, Niihau, or Kahoolawe, and (D) 10 or more BIARC members.

Class B requirements: Work 50 Hawaiian stations, to include the islands of Hawaii, Maui, Molokai, Oahu, and Kauai, and 5 or more BIARC members.

Class C requirements: Work 25 Hawaiian stations, to include the islands of Hawaii, Maui, Oahu, and Kauai, and 3 or more BIARC members.

Address all award applications to the Big Island Amateur Radio Club, PO Box 1688, Kamuela HI 96743.

Take your favorite H.T. out for a drive tonight.

VISA or MASTERCARD for same day shipment

For $64.95 you get the most efficient, dependable, fully guaranteed 35W 2 meter amp kit for your handy talkie money can buy.

Now you can save your batteries by operating your H.T. on low power and still get out like a mobile rig. The model 335A produces 35 watts out with an input of 3 watts, and 15 watts out with only 1 watt in. Compatible with IC-2AT, TR-2400, Yaesu, Wilson & Tempo! Other 2 meter models are available with outputs of 25W and 75W, in addition to a 100W amplifier kit for 430MHZ.

HUNTING LIONS IN THE AIR CONTEST

Starts: 1200 GMT January 9
Ends: 1200 GMT January 10

The contest is sponsored by Lions Clubs International and coordinated by Lions Club Rio de Janeiro Arpoador, Brazil. Participation in the contest is open to all duly-licensed radio operators, Lion and non-Lion. There are two modes—phone and CW. Participation in both modes is allowed but points are counted separately. All amateur stations participating must operate within their licensing regulation. Separate categories will exist for single operator and radio clubs/societies. Multi-operators may participate, but each prefix must be listed on the log.

Use all bands, 80 through 10 meters. Only one QSO with the same station on each band may be counted. Remember that phone and CW are counted separately!

EXCHANGE:

RS(T) and sequential QSO number. When contacts are made with Lions and Leos, the name of the Lions Club or Leo Club contacted should be clearly identified.

SCORING:

QSOs within the same continent count 1 point while those between different continents count 3 points. Score 1 extra bonus point for each QSO with a member of a Lions Club or Leo Club and 5 points for a QSO with a member of the Lions Club Rio de Janeiro Arpoador. Contacts between Brazilian stations and members of the Arpoador club will count only 2 extra points.

AWARDS:

Lions Club International will present trophies for first, second, and third place on both modes in both categories. Fourth through tenth places will receive plaques. In addition, each log sent by participants, radio clubs, or radio societies with a minimum of 5 contacts will receive a special certificate. The contest committee also will select and award the most active Lions Club participating in the contest.

ENTRIES:

Keep a separate log for each mode. Each participant will note in the logs the callsign and information exchanged. Confirmation of contacts will be made by comparing the logs of the participants. Participants should send their logs not later than 30 days after the contest to: Contest Committee—Hunting Lions in the Air, Lions Club of Rio de Janeiro Arpoador, Rua Souza Lima #149, Apt. 402, 22081 Rio de Janeiro, RJ, Brazil.

WORKED ALL MORTON CONTEST

0001 GMT January 9 to 2400 GMT January 10 and 0001 GMT January 16 to 2400 GMT January 17

The Worked All Morton Award will be issued to those hams who have QSOs with five or more members of the Morton Amateur Radio Club or residents of Morton, Illinois, during the contest periods. To receive the award, applicants should send log information listing at least five Morton contacts along with a large SASE to: Morton ARC, 701 Columbus Ave., Morton IL 61550.

TEXAS QSO PARTY

Starts: 0000 GMT January 23
Ends: 2400 GMT January 24

Sponsored by the West Texas Amateur Radio Club of Odessa, Texas. Use all bands and modes. Each station may be worked on each band and each mode. Mobiles may be worked again upon each county change. Single-operator entries only. CW QSOs must be in CW subbands only.

*Plaque. **Contest chairman—ineligible for awards. All others, certificate winners.

EXCHANGE:

QSO number (beginning with 001) and state, province, country, or Texas county.

FREQUENCIES:

Novice—3710, 7110, 21110, 28110; Phone—3940, 7260, 14280, 21370, 28600; CW—3565, 7065, 14065, 21065, 28065.

SCORING:

All non-Texas stations score points as follows: phone contact with fixed station in TX = 1 point; CW contact with fixed station in TX = 2 points; phone contact with mobile station in TX = 5 points; and CW contact with mobile station in TX = 7 points. Multiply by the number of Texas counties worked (254 max.).

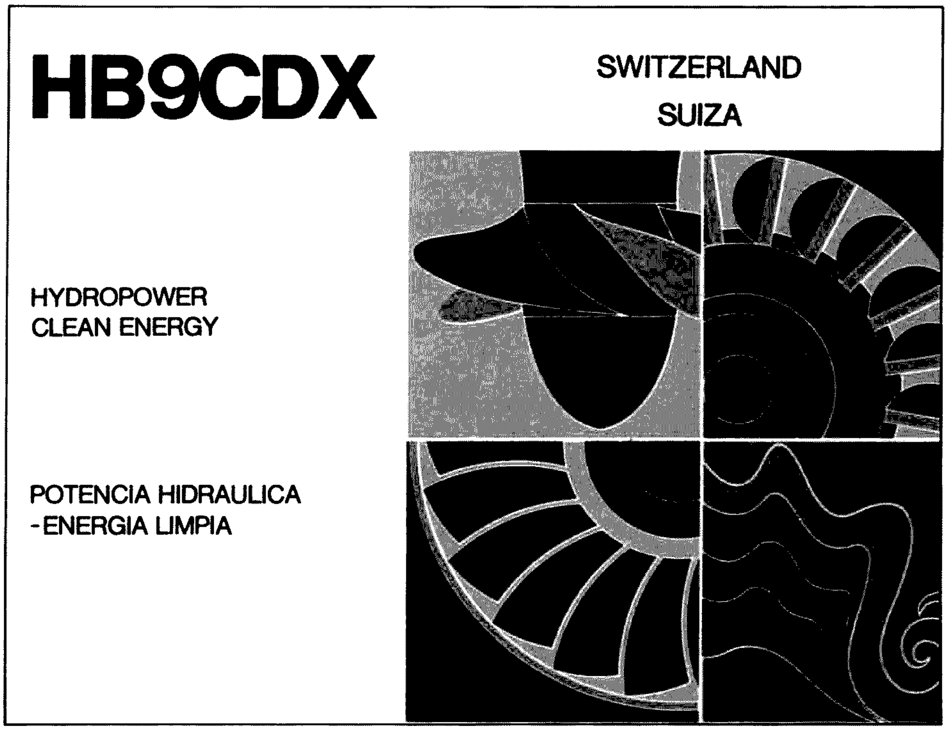
All Texas stations score 1 point per contact on phone, 2 points on CW regardless of fixed or mobile. Multiply by the number of states, countries, and Canadian provinces worked.

AWARDS:

Plaques to top scores: US, US-Novice, DX, Canada, Texas fixed, Texas mobile, Texas Novice. Certificates to top score in each state, country, and province. Certificates also to top 10 Texas stations. Special awards as activity dictates.

ENTRIES:

All logs must be received by March 15th. Mail entries to: WTARC, PO Box 9944, Odessa TX 79762-0041.



QSL OF THE MONTH: HB9CDX

This colorful card was submitted by Swiss amateur Hans K. Wagner HB9CDX. It's an example of how your card can reflect a personal interest—in this case, hydroelectric power.

If you would like to enter our contest, put your QSL card *in an envelope* and mail it, along with your choice of a book from *73*'s Radio Bookshop, to *73 Magazine*, Pine Street, Peterborough NH 03458, Attention: QSL of the Month. Entries which do not use an envelope (the Postal Service does *occasionally* damage cards) and do not specify a book will not be considered.

THE GREAT NORTH DAKOTA QSO BINGE

0000 to 0800 and 1600 to 2400 GMT January 23, and 0800 to 1600 GMT January 24

Sponsored by the Red River Radio Amateurs of Fargo, North Dakota.

EXCHANGE:

RS(T) and state, country, or North Dakota county. Novices, please indicate Novice status.

FREQUENCIES:

Phone—1815, 3905, 7280, 14280, 21380, 28580; CW—1810, 3540, 7035, 14035, 21035, 28035; Novice—3725, 7125, 21125, 28125. All frequencies plus or minus 10.

SCORING:

Phone contacts count 10 points, CW count 20, and RTTY

NEWSLETTER CONTEST WINNER

W9CCU — WHEATON COMMUNITY RADIO AMATEURS

HAMLETTER

Picking a monthly winner for *73's* Newsletter Contest is no easy task. There are literally hundreds of entries to sift through. Each month we narrow the field to four or five outstanding publications and then make the tough decision.

Almost without fail, each month's collection of runners-up has included at least one newsletter from a Chicago area club. For some reason unknown to us, the newsletters coming from that part of the country are usually first-rate. Perhaps there is some sort of inter-club rivalry? This month, a nineland publication finally clawed its way to the top, with the winner being *The Hamletter*, published by the Wheaton Community Radio Amateurs.

This suburban Chicago group's newsletter sports a two-color printing job on the front page and is chock full of black and white photos. But in the end it was a rather small detail that brought victory to *The Hamletter*. Should a copy of this publication fall into the hands of someone who is not a club member, he or she will find plenty of information about the club. A collection of helpful facts can be found every month on the newsletter's masthead. In addition to listing the names and calls of the club officers and newsletter staff, you'll find a mailing address for the club, details about the club meeting time and place, plus a rundown on the club nets and repeaters. This may seem like "obvious" information but for any new or prospective member it can be indispensable.

A newsletter is built from a collection of little details like the masthead. Sometimes you can make subtle changes in your style or layout that will outstrip the improvements of a major reorganization. Establishing a regular format for a publication can give it an identity, but sticking to something because "it's always been that way" may lead to stagnation. Perhaps in 1982 your club can concentrate on the little things; sometimes they make the biggest difference. Keep those newsletters coming!—N8RK.

1st ANNUAL 40- AND 80-METER PHONE CONTEST

SPONSORS:
73 Magazine, Peterborough, New Hampshire 03458

CONTEST PERIODS:
40-Meter Event—0000Z to 2400Z January 9, 1982
80-Meter Event—0000Z to 2400Z January 10, 1982

MISCELLANEOUS RULES:
Work as many stations as possible on 40- and/or 80-meter phone during the specified times of allowable operation. The same station may be worked once on each band. Crossmode contacts will not count. Single-operator stations may operate a total of 16 hours on each band. All multi-operator stations may operate the entire 24-hour period on each band. Off periods must be noted in your logs and on your summary sheet. Off periods are no less than 30 minutes each.

OPERATOR CLASSES:
(A) Single-operator, single transmitter, phone only
(B) Multi-operator, single transmitter, phone only

ENTRY CATEGORIES:
(1) 40-meter band only
(2) 80-meter band only
(3) 40- and 80-meter bands

EXCHANGE:
Stations within the continental US and Canada transmit an RS report and state, province or territory. All other stations, including Alaska and Hawaii, transmit RS report and DX country.

POINTS:
A station may be worked once on each band. US/VE stations earn 1 QSO point per contact with the 48 states and Canada, 2 points for all others. DX stations (including Alaska and Hawaii) earn 1 QSO point per contact within your own country, 2 points for all others. Contacts made between 1000 and 1400 local time score twice the normal points per contact. Indicate points per contact on your log sheet.

MULTIPLIERS:
1 multiplier point is earned for each US state (48 max.), each Canadian province or territory (12 max.), or each DX country worked on each band.

FINAL SCORE:
Total QSO points times total multiplier points equals claimed score.

CONTEST ENTRIES:
Each contest entry must include a log for each band in your entry category, a dupe sheet for each band, a contest summary, and a multiplier checklist for each band. We recommend that contestants send for a copy of the contest forms. Enclose an SASE to the contest address listed below.

ENTRY DEADLINE:
All entries must be postmarked no later than February 11, 1982.

DISQUALIFICATIONS:
Omission of any required entry form, operating in excess of legal power, manipulating of contest scores or times to achieve a score advantage, or failure to omit duplicate contacts which would reduce the overall score more than 2% are all grounds for immediate disqualification.

AWARDS:
Contest awards will be issued in each entry category in each of the continental US states, Canadian provinces and territories, and each DX country represented. A minimum of 5 hours and 50 QSOs must be worked to be eligible for contest awards.

CONTEST ADDRESS:
Send an SASE to: Whidbey Island DX Club
2665 North Busby Road
Oak Harbor, Washington 98277

count 50. North Dakota stations count an additional 100 point bonus for working five Novices. North Dakota stations multiply score by total of states, provinces, and countries per band and mode. Others multiply by counties worked per band and mode (max. of 53 counties).

ENTRIES AND AWARDS:

Certificates to state and province winners. Plaque to North Dakota winner. Mail logs with usual certification by February 28th to: Bill Snyder WØLHS, Box 2784, Fargo ND 58108-2784.

CQ WORLDWIDE 160-METER CONTEST—CW

Starts: 2200 GMT January 29
Ends: 1600 GMT January 31

EXCHANGE:

RST plus a three-digit contact number starting with 001. US stations include state and Canadians include province.

SCORING:

US and Canadian stations count 2 points per QSO with other W/VE/VO stations; DX contacts are 10 points each.

DX stations count 2 points per QSO with stations in the same country, 5 points with stations in other countries. QSOs with W/VE/VO stations are 10 points each.

All stations count one multiplier point for each US state, VE province, and DX country. KH6 and KL7 are considered DX. Final score is total QSO points times the sum of multipliers.

AWARDS:

Certificates to the top scorers in each state, VE province, and DX country. Additional awards if the score or returns warrant.

Two plaques are being awarded by the West Gulf ARC, both for single operators—one for the highest scoring US station and the other for Europe. The World Champion in the contest will receive the John Doremus WØAW Memorial Plaque from friends of WØAW. This plaque can be won only once by the same station in a three-year period.

PENALTIES:

Three additional contacts will be deleted from the score for each duplicate, false, or unverifiable contact removed from the log. A second multiplier also will be removed for each one lost by this action.

Violation of the rules and regulations pertaining to amateur radio in the country of the contestant or the rules of the contest, or unsportsmanlike conduct or taking credit for excessive duplicate contacts or multipliers will be deemed sufficient cause for disqualification. Disqualified stations or operators may be barred from competing in *CQ* contests for a period of up to three years.

ENTRIES:

Sample log and summary sheets may be obtained from *CQ* by sending a large SASE with sufficient postage to cover your request. It is not necessary to use the official form; you may use your own. Logs should have 40 contacts per page, show time in GMT, and numbers sent and received; there should be separate columns for QSO points and multipliers. Indicate the multiplier only the first time it is worked.

Mailing deadline for CW entries is February 28th. Logs can

3rd ANNUAL INTERNATIONAL 160-METER PHONE CONTEST

SPONSORS:
73 Magazine, Peterborough, New Hampshire 03458

CONTEST PERIOD:
0000Z January 16, 1982, to 2400Z January 17, 1982

OBJECT:
To work as many stations as possible on 160-meter phone in a maximum of 36 hours of allowable contest time. Multi-operator stations may operate the full 48-hour contest period. Stations may be worked only once!

ENTRY CATEGORIES:
(1) Single operator, single transmitter, phone only (2) Multi-operator, single transmitter, phone only

EXCHANGE:
Stations within the continental US and Canada transmit RS report and state, provinces or territory (i.e., 59 Iowa, 55 Ontario, etc.). All others transmit RS report and DX country.

POINTS:
Five (5) points will be earned for each valid contact with stations in the continental US and Canada. DX contacts outside the continental US and Canada score ten (10) points each. This year for the first time, an additional 5 points ***bonus*** may be earned for each contact made during the hours of *1000-1400 local time* on either day of the contest.

MULTIPLIERS:
1 multiplier point will be earned for each of the 48 continental states, twelve (12) Canadian provinces/territories, and DX countries outside the continental US and Canada worked during the contest.

FINAL SCORE:
Total OSO points times total multiplier points equals claimed score.

CONTEST ENTRIES:
Each contest entry must include logsheets, dupe sheets for 100 contacts or more, a contest summary sheet and a multiplier check sheet. Please note those contacts made between 1000-1400 local time so you'll be sure to get appropriate contest credit.

ENTRY DEADLINE:
All entries must be postmarked *no later than February 18, 1982.*

DX WINDOW:
Stations are expected to observe the DX window from 1.825-1.830 MHz as mutually agreed by top-band operators. Stations in the US and Canada are asked not to transmit in this 5-kHz segment of the band.

DISQUALIFICATION:
If contestant omits any required entry form, operates in excess of the legal power authorized for his/her given area, manipulates operating times to achieve a score advantage, or fails to omit duplicate contacts which may reduce the overall score more than 2%, disqualification may result.

AWARDS:
Contest awards will be issued in each entry category in each of the continental US states, Canadian provinces/territories, and each DX country. A minimum of 5 hours and 50 QSOs must be worked to be eligible for contest awards.

CONTEST ADDRESS:
To obtain information, entry forms, or to submit a contest entry, forward a ***self-addressed stamped envelope*** to:

160-Meter Phone Contest
Dan Murphy WA2GZB
Post Office Box 195
Andover NJ 07821 USA

be sent directly to the 160 Contest Director, Don McClenon N4IN, 3075 Florida Avenue, Melbourne FL 32901 USA. Alternatively, they can be sent to *CQ*, 160-Meter Contest, 76 North Broadway, Hicksville NY 11801 USA.

TRIPLE CROWNS OF QRP

This is a new award, instituted in 1982 by the QRP Amateur Radio Club International (QRP ARCI). The triple crowns are three trophies for the leading scores in the three categories of the club's annual spring and fall QSO parties, which are open to members and non-members alike. Special certificates will go to the runners-up as well.

The engraved trophies will be awarded the QRP operators whose combined scores from the spring SSB QSO party and the fall CW competition top those of other entrants. Trophies will be awarded in these categories: (1) The top US or Canadian QRP station, (2) the leading non-W/VE QRP station, and (3) the front-running Novice or Technician QRP station (based on results of the fall CW contest only).

To be eligible for one of the triple crowns, operators must enter both QSO parties (except Novices and Technicians) because the awards will be based on their combined scores. Winners will be announced in the January, 1983, issue of *QRP Quarterly*, the club publication, which also will publish worldwide results.

The Triple Crowns of QRP will be awarded in addition to the awards issued for individual performances in the fall and spring QSO parties, whose dates will be announced later.

Those contests will continue to cite first and second place overall and top winners from each state, province, and country.

SECOND ANNUAL MICHIGAN QRP CLUB CW CONTEST

Starts: 1500Z January 16
Ends: 1500Z January 17

A CW-only, all bands, 160-to-10-meter QRP contest. Contest is open to all amateurs, and all are eligible for awards. Calling method: CQ CQ CQ QRP DE (your callsign).

EXCHANGE:

RST, QSO number, and power output.

SCORING:

Each station will be competing within its own state (W), province (VE), or country in one of the three categories: (1) one Watt or less of output power; (2) five Watts or less of output power; and (3) over five Watts of ouput power.

Each contact is worth one (1) QSO point. Multiply total QSO points (all bands) by the number of states/provinces and countries worked per band for total points. Bonus multiplier—emergency power (100% natural or 100% battery) times 1.5 of total.

AWARDS:

Certificates will be awarded to the highest scoring station in each state (W), province (VE), and country.

ENTRIES:

Log information must include: full log data with a sepa-

rate log for each band, name, address, equipment used, and power output. Logs must be received by the contest manager no later than six (6) weeks after the end of the contest. (W) and (VE) please send an SASE, and all others please send two IRCs if contest results are desired. Send all logs to: Contest Manager, Michigan QRP Club, 281 Crescent Drive, Portland MI 48875.

FIFTH ANNUAL INTERNATIONAL SSTV CONTEST
1500 to 2300 GMT March 13
1500 to 2400 GMT March 14

The contest is sponsored by *73 Magazine*, R. Brooks Kendall W1JKF, and Dave Ingram K4TWJ. It is always held on the second full weekend of March. All amateur bands between 3.5 and 29.7 MHz may be used.

EXCHANGE:

Exchange of pictures should include callsign, RST report, and contest number. FCC rules require verbal exchange of callsigns of US stations. Do not include contact number.

SCORING:

One point for each station worked. A station may be worked once on each band for credit. 1 point for each state or province worked. 5 points for each country worked, but only once for 5 points. 5 points for each continent worked, but only once for 5 points. Total score is the sum of all the credits. Excessive discrepancies in the contest entry may cause disqualification. Entries become the property of the contest committee. The decisions of the contest committee are final.

ENTRIES:

Activity sheets should show station worked, state or province, country, and band (80, 40, 20, 15, 10). Summary sheets should show number of stations worked, number of states or provinces worked, number of countries worked, number of continents worked, and total score. Contest entries should be postmarked no later than April 30, 1982. Top scorer will be awarded a certificate and a year's subscription to *73 Magazine*. Certificates also will be awarded to the top scorer for the most countries worked, and also for the most continents worked.

Send entries to either R. Brooks Kendall W1JKF, 10 Stocker Street, Saugus MA 01906, or David Ingram K4TWJ, Eastwood Village, No. 1201 South, Rt. 11, Box 499, Birmingham AL 35210.

FUN!

THE YEAR IN REVIEW

Here's for 1981! Now *that* was a year. Remember the great songs we listened to on 2 meters? How about those wonderful movies we watched on our MDS downconverters? I don't know about you, but I feel very nostalgic about that year. It seems, as the old saying goes, like it was only yesterday.

Obviously, ham radio had its usual happenings in 1981. The customary array of scandals, court actions, FCC denials, and net jammers—all in the name of international brotherhood, of course. So, with a flutter in our voice and a crack in our heart, let's relive 1981 all over again. A year of destiny!

ELEMENT 1—CROSSWORD PUZZLE (Illustration 1)

Across

1) 1981 FCC bombshell proposal (2 words)
7) What the FCC proposes to call our service
8) K2AGZ
9) Synonym for frequency hogs
11) Popular Soviet DXpedition prefix during 1981
14) What the FCC said to expanded 160-meter privileges in 1981
16) ______ do you do it?
18) 1981: a weak year for many ham dealers to ______ rigs
19) A 2-meter rig (abbr.)
20) Not CW, not RTTY, not Fax, not SSTV . . .
21) Number of bands covered by a monobander
22) Computer ______chart
24) "Knights of Malta": now ______ DXCC
25) Nobility or DXCC running total
26) Spain
27) Interrupted code (abbr.)
28) What a contest should be
30) Propaganda station (abbr.)
32) Ham radio legend
33) What you did at your club's picnic last summer
34) Proposals for this new spot were firmed up during 1981 (2 words)

Down

1) FM tone (abbr.)
2) Expression of discovery
3) Norway
4) This and a leg would buy you a new rig during 1981
5) What many hams thought 1 across was
6) "Fruit" often found on RTTY these days
8) Many hams headed here again last spring
10) He introduced a bill affecting hams in 1981
12) FCC began calling this a "siemens" in 1981
13) Amateur space program's anniversary last year
15) Electromagnetic range
17) Ham radio turns us ______
22) New 1981 FCC head honcho, big cheese, numero uno, Mr. Big, top dog
23) Austria
29) What the ARRL's directors said to raising dues
30) FCC rule (abbr.)
31) Travel plans of many DXpeditions were complicated by the firing of some of this agency's workers (abbr.)

ELEMENT 2—MULTIPLE CHOICE

1) During 1981, the FCC issued a number of amateur stations special authority to experiment with a new communications mode. This

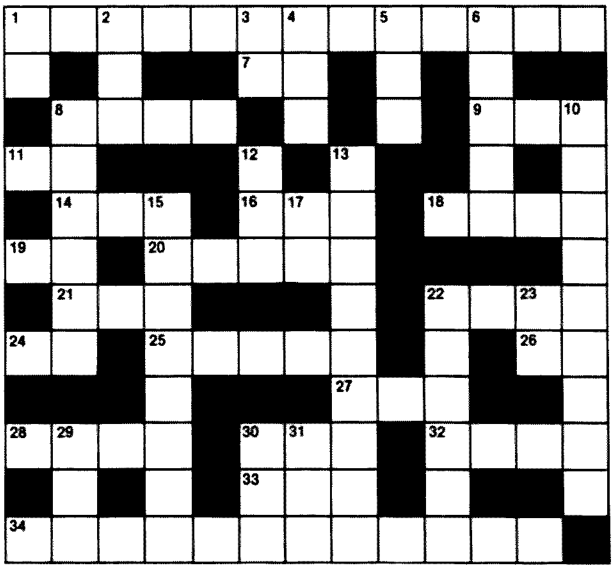

Illustration 1.

technique, which uses 10 to 100 times the bandwidth of conventional modes, is known as:

1) Spread Spectrum
2) Spread Sideband
3) Spread Frequency
4) Packet Radio

2) According to the FCC, John W. Munson, Jr., K6EOA, was sentenced to 3 years probation, fined $500, and ordered to undergo psychotherapy for saying the following over the air:

1) "Is this frequency in use?"
2) "I would love to shoot me a couple of Feds."
3) "Help, help! My boat is sinking!"
4) "Five-nine, Cal."

3) It's been a rough year for the ARRL Central Division. First, their director is "fired," next, the recall balloting of his successor gets fouled up. Exactly what problem afflicted the recall election?

1) Ballots went to members of the Hudson Division.
2) The League forgot to enclose ballots in many of the envelopes they sent out.
3) Ballots were mailed with insufficient postage.
4) The ballots got lost at the bureau.

4) OSCAR 9, launched on October 6, 1981, was built by hams from what country?

1) United States
2) Great Britain
3) Japan
4) West Germany

5) Another ARRL scandal had something to do with QSL cards. What happened?

1) A bunch of 6-land hams submitted phony pasteboards for DXCC credit.
2) The League lost thousands of WAS QSLs when they were accidentally dumped in a paper shredder.
3) The ARRL announced that after July 1, 1981, they would no longer return OSLs submitted for DXCC awards.
4) A League vice director was caught sending in forged QSLs for WAC.

ELEMENT 3—MATCHING

Even with a collapsing economy, manufacturers in 1981 brought out the usual array of new ham stuff. Here, match the product to its maker.

Column A		Column B	
1) ST-7/T	6) 100	A) Heathkit	F) TriggerTronix
2) IC-3AT	7) S-4	B) Yaesu	G) Hal
3) FT-ONE	8) MBA Reader	C) Santec	H) Bearcat
4) CT2100	9) Micro-RTTY	D) Tempo	I) Kenwood
5) TR-2500	10) μMatic	E) Icom	J) AEA
			K) Kantronics

ELEMENT 4—TRUE-FALSE

	True	False
1) In 1981, the FCC eased amateur ID rules.	______	______
2) The FCC began the practice of issuing special event callsigns again last year.	______	______
3) The FCC took action, in 1981, to take away our band at 1215 MHz.	______	______
4) OSCAR 9 has on-board SSTV capability.	______	______
5) The first US packet repeater became operational during 1981.	______	______
6) Last year, many African countries began pushing for the creation of a fourth ITU region.	______	______
7) In last year's FUN! poll, 14% of the participants admitted to jamming other stations.	______	______
8) Bo Derek became a Novice in 1981.	______	______
9) An FCC 1981 working paper proposed, in part, establishment of a code-free VHF ham ticket, amateur privileges on some CB segments, and an expansion of Technician privileges.	______	______
10) The technical breakthrough of 1981 was the development of a 3-element, top-performance, triband beam that could fit in your pocket.	______	______

ELEMENT 5—CRYPTIC PUZZLE

By using a standard substitution code, decipher this message: MH PYY MYCQKH CXMC MPPVYCVB KNW XKUUL QH MH QHBQWVYC FML FMO CXV VDQJQHMCQKH KP CXV PQWOC-YDMOO WMBQKCVDVSXKHV DQYVHOV

THE ANSWERS

Element 1:
See Illustration 1A.

Element 2:
1—1 Better save up for that new "spectrum spreader."
2—2 And they took away his ham ticket, too!
3—2 The problems never cease.
4—2 Gee, a G-sat.
5—1 Ever wonder why anybody would even *want* to cheat for a DXCC?

Element 3:
1—C, 2—E, 3—B, 4—G, 5—I, 6—H, 7—D, 8—J, 9—K, 10—A.

Element 4:
1—True. Now IDing is strictly a one-way street.
2—False. Well. . . I can dream, can't I?
3—True. In accordance with WARC wishes.
4—True. Stand outside and wave as it passes.
5—True. KA6M/6 is San Francisco's "digipeater."
6—True. Four's company. . .
7—True. Amazing, no?
8—False. The line of Elmer volunteers forms on the right.
9—True. The line to comment also forms on the right.
10—False. And I've also got a bridge in Brooklyn you may be interested in.

Element 5:
Coded as follows:

A	B	C	D	E	F	G	H	I	J	K	L	M	N	O	P	Q	R	S	T	U	V
M	U	Y	B	V	P	A	X	Q	Z	I	D	J	H	K	S	R	W	O	C	N	E

W	X	Y	Z
F	T	L	G

AN FCC ACTION THAT AFFECTED OUR HOBBY IN AN INDIRECT WAY WAS THE ELIMINATION OF THE FIRST-CLASS RADIOTELEPHONE LICENSE

SCORING

Element 1:
Twenty points for the completed puzzle, or ½ point for each question correctly answered.

Element 2:
Four points for each correct answer.

Element 3:
Two points per match.

Element 4:
Two points for each correct answer.

Element 5:
Twenty points for the completed puzzle.

P	L	A	I	N	L	A	N	G	U	A	G	E
L		H			A	R		A		P		
	D	A	V	E		M		G		P	I	G
Y	A				M		T			L		O
	Y	E	S		H	O	W		S	E	L	L
H	T		P	H	O	N	E					D
	O	N	E				N		F	L	O	W

T	E	N	M	E	G	A	H	E	R	T	Z	

Illustration 1A.

How well did you remember '81?

1-20 points—Comatose during 1981
21-40 points—"It's kinda fuzzy"
41-60 points—"I remember it well"
61-80 points—"Like it was yesterday"
81-100+ points—Perfect recall

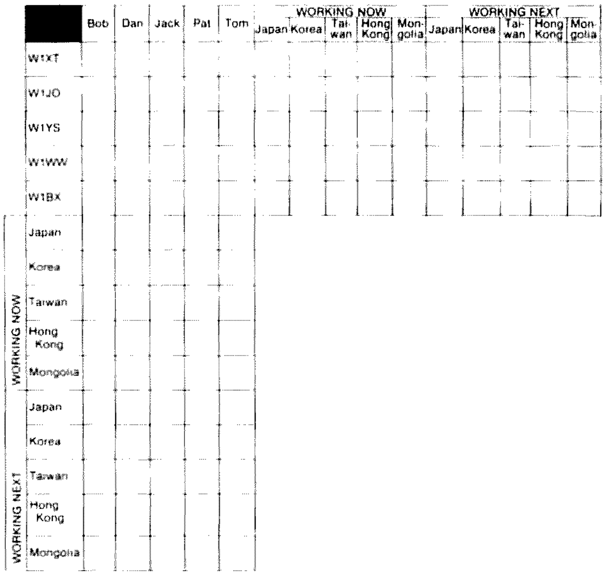
READER'S CORNER

Do you have ham-related puzzles you would like to share with FUN's readers? Then send them in for a chance to see your name in print. This month's contribution is by Bob Young W1MXI, of Belmont, Massachusetts.

Five hams set up a schedule with five DX stations.They agreed to use five different frequencies, and it was also agreed that the five hams would work the DX stations in a prearranged sequence. From the following clues, determine each ham's call, the DX station each is now working, and the DX station to be worked next. (*Ed. Note:* Names and callsigns do not represent any living amateurs.)

A) The rotation sequence is the same for each ham.
B) Bob, who is not W1XT, will work Mongolia next.
C) W1JO will not work Hong Kong next.
D) Tom, W1XT, the ham now working Mongolia, and the ham who will next work Taiwan are four of the five hams.
E) Jack, who previously worked Taiwan, will not next work Hong Kong.
F) Pat is neither W1WW or W1JO, nor is she now working Hong Kong.
G) One of the hams is Dan, whose call is W1YS.
H) Tom is not W1WW.
I) The ham who will next work Korea is not now working Hong Kong.
J) W1BX will not be working Hong Kong next.
K) Jack is not now working Mongolia.

Send in your answers. We'll print the name and call of everyone who solves this puzzle.



CORRECTIONS

IC-2 owners who attempt the MARS modification described on page 113 of the October, 1981, issue of *73* may not find a *brown* jumper on the underside of the MHz thumbwheel switch. Another color of wire may have been used. Avoid any brown jumper that is not located on the switch.

Tim Daniel N8RK
***73 Magazine* Staff**

In building the "Lab-Quality High I Supply" that appeared in your March and April, 1980, issues, I have encountered several problems that, as far as I know, were never mentioned in your corrections column. The problem is in the current-limiting circuit and its connection to the rest of the supply.

Pin 7 of IC2 will go low when the current falls *below* the set level, not above it as the article states, Also, when pin 7 goes low it will pull pin 2 low, causing an *increase* in output instead of a decrease. This results in the pass transistors running wide open when the current falls below the set level and regulation to the set voltage when excessive current is drawn.

I solved the problem by switching the connections 16 and P on the edge connector and connecting the anode of D3 to pin 3 of IC2 instead of pin 2. A simpler solution that should work is to reverse D3.

The supply works fine now and I have been running my HF rig with it. Thanks for the good construction article. I think *73* is one of the best magazines available for good construction and theory articles for those of us who like to home-brew our equipment.

Jim Skinner AC7C
1032 5th Street
Bremerton WA 98310

Reader Jim Skinner AC7C (this is a call?) has made some good points on the article, "Build This Lab-Quality Hi I Supply," as featured in the March and April, 1980, issues of 73 *Magazine. Of all the projects I have had published in* 73*, this one has shown the most interest. To date I have received over 44 queries on it, a record. Most all of the letters concerned substitutions of the power transistors with house-numbered devices. A few others concerned the design itself. One reader queried about the overcurrent shut-down circuitry. From what I have been able to discover, this reader (and Jim) have the inputs of the op amp comparator reversed. That will cause the problem he mentioned. Let me close by saying that I am delighted with the interest readers have shown in the project; it surpassed anything I could have imagined back in 1976 when it was designed.*

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 10

the gap. Setting up a RTTY machine and a couple of CW stations is not going to make it. I've seen so many ham attempts at showing off at malls and fairs, but with nothing to draw in the people. This is show business, too. . . and you have to get 'em in with something dynamic. A couple of rigs and operators, sitting behind a table, is not show business.

Okay. . . now *you* write the articles and tell us how to get things moving.

FRUIT BASKET LEAKS

His Majesty King Hussein (JY1) paid our country a visit recently. After some heavy-duty meetings in Washington, Hussein headed out to Los Angeles. He must not read our Looking West column. At any rate, the L.A. hams got all excited when Hussein called in on the Henry repeater and began working the lists of stations anxious to say hello. Wonder of wonders, particularly for that area, everyone behaved. . . probably for the first time in several years. The whole group was proud as hell of their ability to cope with royalty and put on a good show.

Frank W6AOA got things set up to do a 20-meter-to-two-meter relay from Jordan that night when His Majesty returned from a dinner engagement. The gang had everything set, waiting for the big moment. Sure enough, a bit late but still game, Hussein arrived back at the hotel and checked into the repeater. At that moment, to the utter dismay of everyone, someone got on and let loose with the four-letter words, reading the king off. That certainly was the time for someone to have a finger on the repeater controls. . . but no one did and Hussein checked out immediately, remarking that he really didn't need that. Everyone felt absolutely terrible about it and you can be sure that there are going to be some major efforts at comparing voice prints of every active station in the area.

On the other hand, considering the way things have been going in L.A., I don't think anyone was really surprised. It has gotten so normal to get on the repeaters and jam them with obscenities that few blink an eye when it happens. Fortunately, that phenomenon is pretty much restricted to Los Angeles. I check in on the repeaters as I travel and I don't hear anything like that anywhere else in the entire world.

Your Majesty, if you happen to read this, I'd like to apologize for all of the good guys. . . and they are in the great majority.

SYNERGISM

If you're not familiar with the term, it has to do with two or more things which, when mixed together, provide more than the sum of the parts. In the case of radio, we have just such a result when we mix in computers. Only a few people have yet grasped the magnitude of the computer/communications mix which is coming up.

You see, as computer prices come down, a result of the economies provided by microcomputers and mass-production efficiencies, they are going to proliferate. But computers are the key to faster, lower cost, and more accurate communications, so our needs for communications facilities are going to grow along with the growth of computers. This, obviously, provides a challenge for amateurs.

Computers already are sneaking into amateur radio via the many keyboards which are being bought for both CW and RTTY communications. Fellows, you haven't seen *anything* yet. ASCII communications is just barely getting started, having been held back for years by the FCC's insistence that amateurs transmit no signals that all of their monitoring stations could not decipher. The monitoring stations, being about twenty years behind radio technology, forced amateurs to be the same.

It is going to take a prodigious communications capability to allow everyone in business to communicate with anyone else via computer. . . instantly. We're going to need efficient high-speed systems and whole new modes of communications. This is where radio amateurs can come in. . . and will, if I have my way about it.

Being the publisher of a growing number of computer magazines, I have to stay on top of the technical developments as well as the sales and uses of these systems. It may be a bit frightening to old-timer hams to contemplate a new generation of hams who are into 26,000 word-per-minute-digital communications, but that is exactly what is ahead of us. . . no matter how much we set our heels in to fight it. The day of CW is, at long last, going to fade away. As much fun as CW may be, it is a remnant of the old spark days and inexcusably inefficient. Will we set up some 50-kHz-wide CW bands in the future for old-timers to get on and bat their slow messages out? Probably.

Sure, it's fun to get on CW and make slow contacts with people. But how much is involved other than fun? We are using a very valuable resource, the radio spectrum, and since there isn't enough there for everybody, one of these days we are going to have to bow to the facts of life: You have to pay your way. There is no free lunch. . . at least not forever. To the extent that amateurs can provide services, we will be able to share in the resources, such as the radio spectrum.

Right now we do provide emergency services. We are living on past glories when it comes to providing trained people for wartime use. . . we're just too far out of date with our CW and phone communications. We're in the past when it comes to providing new inventions and pioneering them. It's been over ten years since we've come up with anything of serious benefit to the world. . . such as FM and repeaters. I wouldn't claim a lot of benefit to the world when it comes to international goodwill, either. Perhaps the FCC was right when they proposed getting rid of the list of reasons for amateur radio to exist in their rewrite of our rules.

One way or another, we either have to bring amateur radio into the 1980s, with old-timers kicking and screaming, or else we are going to have to watch over the demise of our hobby. We really do have to pay our freight.

With the worlds of communications and computers coming together, we have an opportunity to be heros again. The more we can invent and pioneer high-speed communications systems built around the needs for computer communications, the more valuable we will be. The more that American amateurs can do this, the stronger will be the American technology. . . and American industry. Don't you really get a little sick of seeing virtually every major step ahead in technology coming from Japan?

Amateurs can again be the elite of our electronics people. The ball will be carried by the youngsters we get into the hobby. The rest of us can cheer them on, help them with experiments, and try not to screw things up any more than is accidental. If you can't carry the flag, at least don't shoot the kid who *is* carrying it for you.

GREEDY GREEN?

In 1960, due to the low interest in building by amateurs, there were very few construction articles in either *QST* or *CQ*. I started *73* feeling that if I published enough construction projects I could get amateurs into building again. I obviously would have done better with the magazine if I had catered to what the mainstream of amateurs wanted. . . gossip and new product reviews.

Sideband had just recently been invented by amateurs, so I ran every article I could on sideband. . . how to build it, how to use it, and so on. Circulation, for a while, slumped as readers wrote in and protested all the sideband information. Sideband, they felt, was a flash in the pan and would soon go away, leaving their age-old AM still king. Eventually, sideband caught on and circulation slowly began to grow again.

It was about this time that I realized that solid state had a big future for amateurs. I published every article I could get amateurs to write about using transistors. Hams began to go solid state. It was a hard uphill climb, with *QST* and *CQ* fighting me every step of the way. In

1968, the technical editor of *QST* lashed out, saying that hams were tube people and that was why *QST* was not publishing transistor articles. Hams would always be tube people. . .transistors were and always would be inferior to tubes. . .a flash in the pan.

Despite the ham industry being almost totally dead, having dropped 85% in ham sales as a result of a proposal to the FCC that ham licensing be turned back to the prewar system of just two licenses, I managed to keep *73* going. We were down to a staff of five in those lean days, but still I stuck to pushing amateur radio and experimenting ahead of considerations of larger circulation.

Just as we were beginning to see the light again, I spotted FM and repeaters as the best thing since sliced bread for amateur radio. In 1969, I started going full blast on FM. I ran hundreds of articles on how to build FM rigs and repeaters, published a wide range of books, started a repeater newsletter, gave FM symposiums around the country. . .all with no help whatsoever from any other ham magazine. The readers responded with their usual enthusiasm. . ."drop dead with FM, it's a flash in the pan." Circulation dropped off as thousands of angry readers cancelled their subscriptions.

Eventually, FM became popular and things picked up again. The advertisers, ignoring the large number of FM and repeater fans in *73*, rushed to advertise their FM equipment in *QST*. . . as usual.

If I wanted to be the Mork and Mindy of ham magazines, I would flood you with articles on CW, telling you how great it is. Every poll shows that hams do not want to change the CW license exam, no matter how destructive it is. So again I am choosing the way I think we must go and I intend to push amateur radio, kicking and screaming, where it needs to go. . . both for the future of amateur radio and for the future of our country. The two, I feel, are closely entwined.

There are several factors which I see as significant as far as the future of amateur radio is concerned. One is that we are using what is still a very valuable resource. . . the radio spectrum. Thus, if we are going to pay our way, we have to provide benefits to both our country and to the world. Much of the future lies in the microwaves and satellite communications, so if we keep our ham technology twenty years behind there will be no space for us where we need it.

By keeping our amateur population down we are able to make do with communications techniques which are twenty to sixty years old and won't have to come to grips with digital electronics and modern technology. If we start growing, this will force us to invent and pioneer better systems. . . just as the overcrowded AM bands of 1960 forced the acceptance of sideband. . . over a lot of old-timer dead bodies.

Unless we take our role as an experimental group seriously, we will eventually be lumped with the CBers into one blah service. . .one which can at any time be pushed out if something more important comes along. Those of us who are using our ham bands just for fun should realize that we got them because past amateurs provided new inventions, emergency service, international goodwill, and one hell of a bunch of technicians for WWII. . . when 80% of the licensed amateurs went to war.

We earned the frequencies we are using and now there are many amateurs who feel that for some reason they have a "right" to them. Amateur bands are plain old radio frequencies and will be parcelled out for the best use that can be found for them. If we use them merely for rag chewing and DX pileups, I guarantee you we will lose out in the long run. Many amateurs really don't care whether there are any ham bands in ten years or not. They want to enjoy them . . . and curse them. . . now, and what happens later is of no consequence.

The long range survival of amateur radio lies in our providing service which is worthy of the frequencies we are using.

Pushing for the growth of amateur radio is silly from a financial point of view. Fortunately, my computer magazines are doing well and can carry *73* through the storms ahead. Perhaps you can understand why I get a bit exasperated when someone writes in and says I'm pushing for more hams in order to make more money from amateur radio.

WORKING THE PILEUPS

Down through the years of operating from relatively rare DX spots, I've tried every known method of sorting out the pileups. The problem, as I'm sure you recognize, is in getting the call letters of the stations calling. . .and it can be a rough problem when there are hundreds of stations trying to get through.

If you have a good strong signal you can sort things out much easier than when you are just barely making it through. A good system for working pileups should allow you to cope with weak signals from your station.

Hardly a day goes by that I don't hear some frustrated DX operator trying to cope with the pileups and failing miserably. His weak signals are being covered up by the stations calling him and no one can tell when he is transmitting, which leads the turkey DXers to just keep on calling, in case the chap might be listening. Some of the DXers will get mad at each other and overlap their calling so no one can ever hear the rare station.

Lists are one way around this, but they are slow and annoying to everyone involved. If one were able to find good, sharp list takers, that system might work reasonably well, with one station taking a list perhaps 10 kHz higher and another 10 kHz lower, each passing along about 20 calls at a time. This *can* work, but it isn't a good system in my experience.

It is difficult for the rare station to give the situation a lot of thought when he is facing the pileups. Most of them blunder along, not really knowing what to do. I suggest that it is a kindness, when you run into a situation like this, for an operator with a good solid signal to take a few minutes of the DX station's time and offer some suggestions on speeding up his process.

The best system I've been able to work out. . .the one which gets me the most contacts per hour. . .which, after all, is what I'm visiting the rare country for. . . is one which can be used with even weak signal strengths. It is one which allows me to work not only the louder stations but right on down to the weak mobiles on channel. It does stick to one frequency rather than spreading the callers all over the band, jamming fifty other contacts.

This system consists of laying down the rules for the callers in no uncertain terms. The rules are simple and must be followed. Any stations which break the rules will be worked, but will not get a card.

1. Stations are to call me for a period of fifteen seconds and then listen.

2. Stations are to call a maximum of three times during the fifteen seconds.

3. Stations are to give the last letter of their call phonetically and nothing else.

4. Operators are to spend their time listening and answer only when requested to.

5. Operators who try to force CW contacts without getting an okay first will not get a card.

6. QSL information will be given every few minutes, so listen, do not request it.

This system allows me to write down the last letter of ten to fifteen different stations during the calling period. I then come back and get the full call of each calling station and exchange signal reports.

When there are too many people calling at one time, I break it up by call area or by country. Sometimes it is handy, where a lot of different countries are calling, to ask for calls according to the number in the call. I've often been surprised when working the States and asking for, say, threes, to have a TF3 or an SM3 call in. . . even UK3. Of course, there are some foreign stations who refuse to understand English and will call without stopping, ignoring all requests. I sigh, work them, and mark the log for no QSL.

When you're on a DXpedition, you don't want to waste any more time than necessary, so you want your contacts to be made as quickly as possible. Also, when you are one of the pilees in a pileup, you want to waste as little of your time sitting around. . . or in yelling into the mike. . . as you can. If you'll encourage DX operators in rare spots to get on the stick and speed up their operations everyone will have more fun. And that's the name of the game. If it isn't fun, we'll stop doing it.

BUNK IN 73

The November DX column in *73* was full of the same old bunk I've been reading for some thirty

years now. Boy, I feel like I'm going through the 1920s and the emotional arguments over spark, with old-timers holding on with "spark forever" slogans.

I see the same old hogwash about CW being able to get through better than phone when signals are weak. The edge used to be a big one when we were using AM. Perhaps the "CW forever" crowd has not noticed that amateurs have invented sideband.

Another old-time rationalization has to do with CW rigs being cheaper than those for sideband. Yeah? The Heath HW-32 put that one away. How many CW-only rigs do you see today? Sure, a CW rig is easier to build, but where are they home-building rigs these days? Don't try to tell me about the poor amateurs in third world countries... they're not on the air because their dictators don't want them on the air, not because equipment is hard to build. Except in the larger countries, it is the wealthier people who are on the air.

Calling all phone ops the equivalent of CBers is baloney... emotional slop.

CW is increasing in use these days because of the digital-electronics systems developed which generate and decipher Morse code. If they would use the equipment with ASCII it would be much more efficient. You need FSK if you are going to combat fading, jamming, noise, and so on.

If we would help people enjoy the use of CW because it is fun and stop trying to lie about it, we'd have a lot more CW operators... and better ones. The biggest boost we can ever give CW is to stop jamming it down the throats of newcomers and using it as a skill filter to keep people from getting ham licenses. We have a technical hobby and I'd like to see entry to it gained via an honest technical exam... without the cheat books from Bash and the League.

MORE DETECTORS

The only thing that may stand between you and a speeding ticket if you happen to be transmitting in a radar trap is a detector. Many hams have been hit with this, as unfair as it is.

It is worth almost any investment to avoid having a chase car stop you, lights aflashing. And if that isn't enough, wait until you face our judicial system. You can read more about the traffic court system in the August issue of *Car and Driver*. The bottom line is that, facts aside, you lose. You will end up paying the fine, your lawyer, and additional insurance premiums. The bottom line makes the cost of the radar detector look cheap.

Our court system is not geared to dispense justice, but rather lo collect fines. It is bigger than you are. The best way to win is not to get into the clutches of the law in the first place. They really don't care how innocent you are and it won't cut any mustard with them.

If you are going to be foolish enough to transmit while you are driving, you'd better figure in another $250 for a radar detector. That will tell you when to shut up while you pass the police radar units.

You want a superheterodyne type of detector. Do not fall for any of the imaginative technical names which are similar... these do not work as well. None of them work that I have tested, and I've tested a bunch. Any of the superhets will do the job you want... whether it be the Whistler Q-1000, the Radar Intercept, the Gul, the Fox, and so on. Superhet, that's the ticket (or lack of a ticket).

So far in my tests I've found that the Cincinnati Microwave Escort is the best. Sometimes the edge is slight... but the S-meter on it is most helpful in giving me an idea of the closeness of the radar unit... and in discerning the home or business radar security systems which I pick up. The Escort is still $245 and sells by mail only. It's made by a bunch of hams in Cincinnati.

While the Escort and the superhet Fox can be easily stuck on the dashboard via some Velcro® tape, the Gul detector is a fat oval unit which is a bit more difficult to mount. Works fine. The J. R. Microwave Radar Intercept unit is flat and designed to snap on the sun visor. A mercury switch turns it on when you flip it down. It is almost as sensitive as the Escort. It wires permanently into the car, a drawback if you like to hide your $250 goodies when you park. If you are sensitive to the police seeing your detector, the Intercept is certainly up out of the way and fairly invisible. I've never had any flack about detectors... even in Connecticut, where I've driven my van with up to seven of them mounted on the visor, dash, and so on.

ARTICLES NEEDED

One of the reasons I bothered to start *73* back in 1960 was that I felt amateurs should read more articles on building things. At that time, the enthusiasm for building had dropped considerably... partly as a result of the drying up of surplus gadgets to work with, but mostly because the two ham magazines of the time, *CQ* and *QST*, were publishing so few construction projects. Indeed, that has continued pretty much unchanged to this day.

Building is *fun*. Today, with a handful of ICs we can build gadgets which were far beyond us only a couple of years ago. Today we have almost unlimited horizons for home-building of experimental gear. With the communications demands of computers, we need to develop new modes of communications and get them to work.

Those of you who *are* building and designing new equipment have a responsibility to come away from the workbench now and then and pass along what you've learned. Your enthusiasm will get more hams to building and they, in turn, will get still more hams interested. We're ready at *73* to help you get your material into good professional finished form.

Writing articles is easy. We do have an author's guide, if that will make you feel better. No charge, so the price is right. Mostly you have to remember to double-space your typing, to use a typewriter with upper and lower case (not a TT machine), leave generous margins... and get your details right. Photos are most helpful. Templates, PC-board layouts, and so on are invaluable.

It is most exciting to be a published author. You will hear about it from your friends for a long time. You'll get ego-boosting mail from all around the world. Hams will remember you on the air for a surprising length of time. And your family may show a new respect. You also get paid for the article, a little nicety which will pay for much of the project in most cases. And if you have something which looks like a commercial product, you could end up with a handsome royalty.

Send your articles to The Editor, *73 Magazine*, Peterborough NH 03458.

Clubs can help with this by getting members to bring in their new construction projects for a short show-and-tell session at meetings. This will not only encourage the chaps who are building, but it also will get more of the club members thinking in terms of giving it a try.

Building has never in history been easier. A few ICs, some perfboard, and almost anything can happen.

WARC-BAND BEACON

As a result of the 1979 World Administrative Radio Conference (WARC), three new HF bands were allocated to the Amateur Service. It will be some time before these bands are made available to US hams for general use. However, the FCC granted W4MB a license for Experimental Station KK2XJM to operate in the three new bands. Below is the operating schedule of the KK2XJM beacon during the first nine weeks of 1982. For further information, to QSL, or to establish special test schedules, contact R. P. Haviland W4MB, 2100 S. Nova Rd., Box 45, Daytona Beach FL 32019.

Date	MHz	Power (Watts)
January 7	10.140	30
January 14	24.930	3
January 21	18.108	3
January 28	18.108	3
February 4	24.930	3
February 11	24.930	3
February 18	10.140	30
February 25	18.108	30
March 4	24.930	30

Everyone has heard of the Ipanema beach at Rio de Janeiro. Our hotel was on Sao Conrado, around the corner. Here I arrived, eyes at half mast, after an all-night, red-eye flight from New York. The plan to stop at Brazil had been a sort of last-minute idea to cater to my fetish for visiting as many countries as possible... bringing me up to 99 if you count the UN building in New York... which I do. If it's good enough for the League, it's good enough for me. Not having arranged a ham license for Brazil, I was left with nothing more to do than rest up...and watch the hang gliders jump off the right-hand knob of Pico da Tijuca and then flutter back and forth for hours in the updraft coming from the ocean up the mountain.

Once rested, if a couple of short naps, a business conference, and a big dinner qualify as rest, we were back out to the airport and on our way to Johannesburg. Even in Brazil we felt the controller strike when our plane arrived from the US two hours late, bringing us into Johannesburg well after midnight. Both computer and ham friends were at the airport, despite the hour...and within minutes I was saying hello via one of the local repeaters to hams all around the city. A long plane ride may be comfortable for a deaf amputee, but the rest of us, with little leg room, kids crying, food every couple of hours, people bumping up and down the aisle, movies being shown...and so on...stagger off the plane disoriented and dazed. My first real awareness of Johannesburg was the next morning, early, when Julius ZS6AF came up to present me with a loaner Kenwood TR-2400 and charger. I opened the window curtains and was taken aback by the view. It was like Chicago or Philadelphia, not Africa and mud huts.

I'll bet you've been wondering what happened to all those old VW beetles. I found them, painted yellow, and being used as taxis in Rio. The chap on the left is trying to get his clothes straightened out after leaving the sardine-can ride, complete with baggage. In New York, when you see something like this it means the chap is being mugged.

Doug Goldman 3D6BG hasn't got a whole lot of signal from this rig, but then he is no pileup fan, so this does what he needs. It's sitting there for visiting hams to operate. Of course, it doesn't hurt if you stay at the hotel Doug has built. You won't find better food anywhere...and I can show you at least a half pound put on there as testimony. Fortunately, ham conditions were stinko so I got a chance to talk with Doug, get around the country and take some pictures...and even rest up a bit...for a change. Hamming comes first, of course ...then food...then my wife...then rest ...just like any other serious ham.

Swaziland looks like this. I'm not sure where they keep all of the African jungles, but I can tell you they don't seem to be in South Africa or Swaziland. Mostly farms in South Africa and idle land elsewhere. That's one of the motel units of Doug's Smoky Mountain Hotel on the left.

Alda Campos, at the right of Sherry, met us at the airport and drove us to our hotel. After we were partially rested she picked us up and took us to see her father's computer store...and plant, making Apple-like computers. I like the eating part of trips. That's her father on the left, Aldenor. It's a big happy family and we did a good job in this meat restaurant...all different kinds of meat. The waiter on the end is hacking off more meat. How do I manage consistently to stay 20 pounds overweight? No problem, I just enjoy meals like this one. Here Sherry and I are doing our best to keep up with endless courses. Computer people can be as nice as hams!

Wayne Green lost in Africa (heh, heh)...I could see the headlines in QST as we struggled to get our rented Cessna started. After an hour of screwing around, it got going... as did we, heading about 300 miles to Swaziland and another country for me. I tried to forget the plane by talking with my HT through the South African repeaters. As we neared Swaziland, I was assured through the Mbabane repeater that my license was in order. I checked the charts and changed from W2NSD/ZS to W2NSD/3D6.

Julius Lieberman ZS6AF, who runs the local ham store and is the importer for South Africa for Kenwood. His station is first rate So is he.

NEW PRODUCTS

TR-2500 HAND-HELD

Trio-Kenwood Communications has announced the new TR-2500, a compact 2-meter FM hand-held transceiver weighing approximately 1.2 lbs., yet including such features as LCD digital frequency display, 10-channel memory with memory scan, built-in five-year lithium memory backup, manual scan, programmable automatic band scan, built-in tunable sub-tone encoder, built-in 16-key autopatch encoder, 2.5 Watts rf output, HI/LO power-output switch, and other features. The TR-2500 comes complete with rubberized antenna with BNC connector, 400 mAh heavy-duty nicad battery pack, and ac charger.

For additional information, contact *Trio-Kenwood Communications, PO Box 7065, Compton CA 90224.*

LEADER LDM-855 DMM

Leader Instruments Corporation, of Hauppauge, New York, now offers a 3½-digit digital multimeter that fills the need for both laboratory and field work. The new LDM-855 offers automatic ranging, semi-automatic zeroing, and a large LCD display for straightforward, hands-free operation. When manual range or function selection controls have been changed, a momentary audible tone is heard. When used in the resistance mode or for checking continuity, the tone is sounded continuously when short-circuit conditions occur. This enables the operator to make tests without having to constantly look at the meter to see if continuity is present.

Other features include an automatic polarity indicator, ac and dc measurement functions, a LO-OHM mode to provide a lower test voltage, and a low-battery warning incorporated into the liquid crystal display.

Dc voltage range is 0.1 mV to 1000 volts with an accuracy of ±0.5% of reading ±0.2% full scale on the 0.2-to-200-volt range. On the 1000-volt range, accuracy is 10 megohms, overload protection is 1000 V dc and ac peak.

Ac voltage range is 1 mV to 1000 volts. Accuracy for the 2-V range is ±1% reading ±0.4% full scale at 40 to 500 Hz. At 0.5 to 1.0 kHz, accuracy is ±1.5% reading ±0.4% full scale. On the 20- and 200-volt ranges, accuracy is ±1% of reading ±0.25% full scale for 40 to 500 Hz, and ±1% of reading ±0.25% full scale for .5 to 1.0 kHz. On the 1000-volt range, accuracy measures In at ±1.5% of reading ±0.25% full scale at 40 to 500 Hz. Input impedance is 10 megohms and overload protection is 1000 V rms.

Ac and dc current ranges are offered from 10 microamperes to 200 milliamperes. Resistance measurements are offered between 0.1 Ohm to 2000 kilohms. The display is a 3/8-inch, seven-segment liquid crystal with a maximum of 1999 maximum. Reverse polarity is indicated, as is over-range and low battery. Primary power requirement is two C-cells. The LDM-855 measures 6-1/8 inches wide, 2-1/4 inches high, and 4-7/8 inches deep. The unit weighs 1.1 lbs. It comes complete with instructions manual, a test lead set, and two C-cells.

For additional information, contact *Leader Instruments Corp., 380 Oser Avenue, Happauge NY 11788.* Reader Service number 487.

LOW-COST ETCHING SYSTEM

Stellmaker Enterprises has designed a high-quality power etching system that is reasonably priced. The kit includes an air pump, air disperser, base with support for 4½-pint plastic tank with cover, mounting screws, and all necessary instructions.

This compact system will etch PC boards up to 6" × 6", which is the size featured in most magazine articles. The acid agitated by the air pump makes for fast and more even etching.

For more information, write *Stellmaker Enterprises, 250 Pequot Trail, Westerly RI 02891.* Reader Service number 485.

TRIO-KENWOOD R-600 RECEIVER

Trio-Kenwood Communications has just announced a new general-coverage communications receiver, model R-600, covering 150 kHz to 30 MHz in 30 bands. The use of PLL synthesized circuitry results in highly accurate frequency control with maximum tuning ease. The unit features an easy-to-read digital display, AM, SSB, and CW reception, built-in i-f filters, noise blanker, rf attenuator, S-meter,

The Trio-Kenwood Communications TR-2500 hand-held.

The Trio-Kenwood Communications R-600 receiver.

front-mounted speaker, and operation from power sources of 100, 120, 220, and 240 V dc, 50/60 Hz. Operation on 13.8 V dc also is possible, using the optional DCK-1 dc power cable kit.

For further information, contact *Trio-Kenwood Communications, PO Box 7065, Compton CA 90220; telephone (213)-639-9000.*

MFJ-955 VLF/MW/SWL ANTENNA TUNER

The new MFJ-955 VLF/MW/SWL preselecting antenna tuner improves reception of 10-kHz through 30-MHz signals. The MFJ-955 connects between your receiver and antenna. You can peak desired signals while rejecting interference and reduce overload, background noise, cross modulation, and intermodulation. Front-panel switching allows push-button selection of two antennas and two receivers, and a front-tuning knob permits tuning for maximum signal strength. The MFJ-955 measures 5-1/2" × 2" × 3" and is housed in a black and eggshell-white aluminum cabinet.

For more information, contact *MFJ Enterprises, Inc., PO Box 494, Mississippi State MS 39762; telephone: (800)-647-1800.* Reader Service number 484.

The MFJ VLF/MW/SWL antenna tuner.

RF-670 SPEECH PROCESSOR

Daiwa has announced a compact audio speech processor that rivals the performance of rf types at an economical price. The photocoupler design delivers a high level of processing with a minimum of distortion. Traditional audio-processor design is handicapped by circuitry time constants that limit the ability of the processor to respond to rapid variations in the level of the input audio signal. The result is distortion and poorer performance. The RF-670's photocoupler/variable-gain amplifier design permits a very rapid response to input levels resulting in clean output. The RF-670 features Velcro® pads for easy mobile or base mounting.

For more information, contact *MCM Communications, 858 E. Congress Park Drive, Centerville OH 45459.* Reader Service number 482.

SURGE SHUNT

The R. L. Drake Company has announced its new model 1549 surge shunt. The surge shunt protects solid-state communications equipment from damage caused by voltage transients entering the antenna system. These transients usually are caused by atmospheric static discharges or nearby lightning strikes.

The surge shunt can be used with both receivers and transceivers with up to 200 Watts output. Convenient UHF-type coaxial connections are used, permitting use into the UHF range.

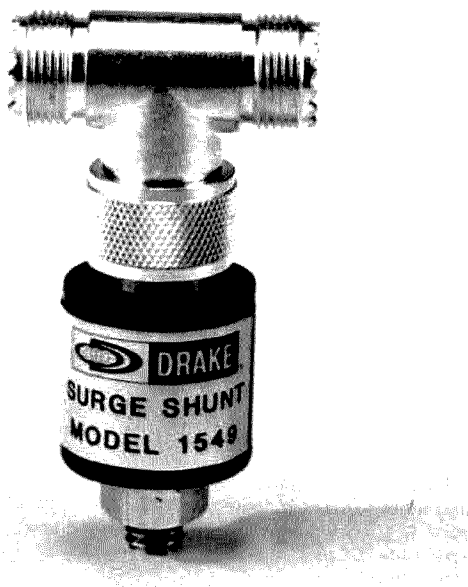
For more information, contact the *R. L. Drake Company, 540 Richard Street, Miamisburg OH 45342; telephone (513)-866-2421.*

MICROCRAFT CODE*STAR CODE READER

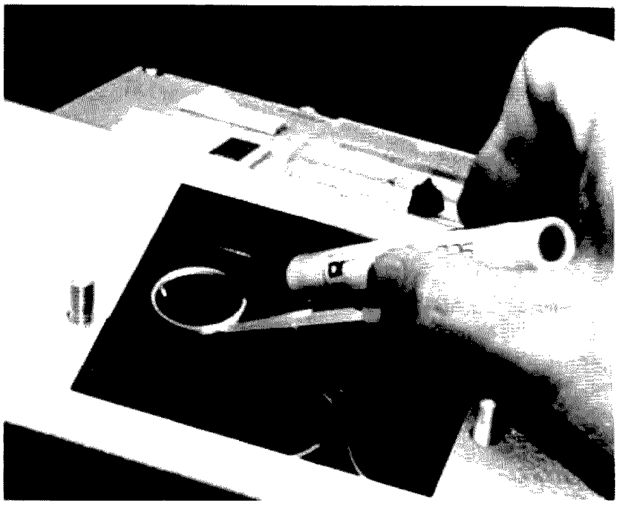
CODE*STAR is a code reader designed for Novices, SWLs, and veteran amateur radio operators. It should also be very useful to persons learning or trying to improve their Morse code skills.

CODE*STAR's microcomputer monitors the incoming signal and converts it to characters on its large easy-to-read LEDs. CODE*STAR decodes Morse

Daiwa's RF-670 speech processor.



Drake's new 1549 surge shunt.



The Desco flashlight/mirror combination.

code, Baudot (RTTY), and ASCII code. There are two specially optimized Morse code ranges with auto-tracking of speed from 3 to 70 wpm. Special proprietary analog and digital filter methods are employed to substantially reduce errors. An automatic gain control circuit providing up to 16 dB gain helps maintain signals under fading conditions. A built-in code-practice oscillator is handy for code practice and learning the code.

CODE*STAR operates on 12 V dc, which makes it ideal for field or mobile applications. An ac adapter is included if you wish to operate it from 120 V ac. As a special option, you can use CODE*STAR to drive a serial or parallel ASCII printer, TV terminal, or computer. This ASCII output port option is available as a kit that mounts inside CODE*STAR's cabinet on the PC board.

CODE*STAR is available as a complete kit or factory wired and tested.

For more information, contact *Microcraft Corporation, PO Box 513, Thiensville WI 53092; (414)-241-8144.* Reader Service number 486.

FLASHLIGHT/MIRROR COMBINATION

Desco Industries, Inc., has introduced the model 227 flashlight/mirror combination. The plastic dental-type mirror clips to Desco's model 225 disposable pocket flashlight to provide an ideal combination for field or workbench. The unit comes complete and ready to use with two AAA batteries included.

For more information, contact *Desco Industries, Inc., 761 Penarth Ave., Walnut CA 91789; telephone (714)-598-2753.* Reader Service number 483.

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randallstown MD 21133

Last month I mentioned a new FSK converter, the FSK-500 from iRL, out in Columbus, Ohio. Let's take a look at this little gem this month.

A few months back, I examined the FSK-500's big brother, the FSK-1000. This box is not really a scaled down 1000, but rather a beneficiary of things learned from the larger unit. The FSK-500 is both a RTTY demodulator and an AFSK (audio frequency shift keying) tone generator. A RTTY modem (modulator/demodulator), if you will.

A look at the receiving, demodulating, end shows quite a performer. Audio input is accepted through a standard phono jack, such jacks being used for all connections but the loop, as a 500-Ohm unbalanced signal. That means that most speaker or "line" outputs will work just fine. The amplitude of this signal may range from 10 mV to 17 *volts* peak to peak! That's some range, folks. The audio is then passed through a limiter, and selectable bandpass filters are available to optimize reception for either "narrow," with a bandpass of 75 Hz and low-pass filter rolloff of 28 Hz, or "wide," with a bandpass of 145 Hz and a rolloff of 60 Hz. The narrow filter is normally used for 170-Hz shift RTTY; the wide position is useful for 850-Hz shift, as commonly used on AFSK, and ASCII transmissions.

Three selectable shifts are also provided. Along with the common 850-Hz and 170-Hz shift, a 425-Hz shift is available. This is useful for copying commercial stations and other non-ham signals. By the way, the shift is selectable independently from the bandwidth, so odd combinations can be easily set up.

Internal mark-hold circuitry and autostart are provided, and the level at which a signal begins to be decoded is adjustable by the front panel "threshold" control. The general function is kind of like a RTTY-squelch control, serving to keep the machine quiet when no one is transmitting.

Tuning is aided by both a meter which shows a mid-scale deflection for mark and a full scale deflection for space, and by LEDs which display the mark or space status of the loop.

Outputs from the FSK-500 include an RS-232 compatible output, called "Data Out," which is useful for driving a video terminal or computer. Of course, interfacing to a standard RTTY loop is provided, but, and this is notable, an internal loop supply is *not* provided. That means you have to supply the 60 mA current from another source. This is not too hard, and we will cover that in a little bit.

As if that was not enough, a "Serial In" jack accepts either "dry" contacts, such as a reed relay or isolated keyboard, or RS-232 levels. This allows a computer to key the transmitter and loop. There is also a provision made for connecting a straight key for the mandatory CW identification.

Remember I called this thing a "RTTY modem"? Well, here is the "mod" part. A built-in AFSK generator provides a low impedance, clean, 50-mV audio frequency shift signal. This can either key a VHF transmitter or AFSK, or, when fed to an SSB transmitter as detailed previously, result in a nice, clean FSK signal.

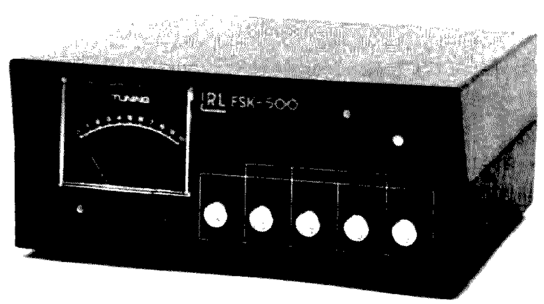
A few more bells and whistles include a transmit/receive remote function and an output able to key the push-to-talk line of most transmitters. Scope outputs are also provided for those of us who like to monitor the RTTY signal on such beasties.

Now, the acid test is not what it looks like on paper or how pretty the case is, although you can see that for yourself in the photo, but how well it performs on the air. I also like to compare new equipment to older units to see if we have gained anything. So what I did was to find a reasonably clear, but not solid, RTTY signal and sit my wife down in front of the revelver and ask her to tune it in. For comparison, I set up my several-year-old ST-6 and asked her to comment on the two.

Allow me to interject that my wife knows about as much about RTTY as most hams know about cooking blintzes. If she could do it, anyone could!

Well, she could, and despite similar tuning indicators on both demodulators, i.e., two lights and a meter, the FSK-500 appeared easier to tune. Now, I don't know if the filters in the ST-6 are more critical than the FSK-500, but I suspect that that is so. However, when we went looking for signals, there was not one that the ST-6 could copy that the FSK-500 could not do as well on. Very impressive.

All in all, the FSK-500 is a very nice little box. For under $250, in a box 7.75 inches wide, 3.25 inches high, and 7.375 inches deep (that does not even fill the size of this page!), you can get a demodulator that may well be all you need on RTTY, Murray, or ASCII for a long time. Check out iRL's advertisement here in *73* or drop them a line at 700 Taylor Road, Columbus, Ohio



The FSK-500 from iRL.

43230. Be sure to tell them you read about the FSK-500 here in RTTY Loop.

Oh yes, about that loop supply. One of the only sacrifices apparent in the design of the FSK-500 is the loop supply. Of course, if you are running a computer-based station, you have no need for a current loop. If that is the case, turn the page and drool over the ads; otherwise, hang in here for a spell. Common teleprinters, such as the Model 15 Teletype®, use a current loop, usually about 150 V dc to 300 V dc, at a constant 60-mA current. It is not hard to design such a supply, and it makes a good construction project for the RTTY-neophyte.

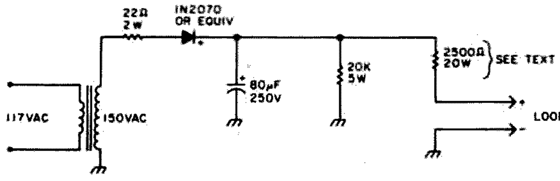


Fig. 1. A local loop supply.

If you have a dc supply (we will worry about where the dc comes from later) providing, let's say, 180 V dc and you hook it up to the selector magnets of your teleprinter, what would happen? After the smoke cleared, you would have a worthless hunk of junk. Why? Remember that the resistance of the selector magnets is in the range of 100 Ohms. If 100 Ohms is placed across a 180-volt source, thinking back to Ohm's Law, it will draw (I = E/R) 180/100 equals 1.8 Amps! That would produce about 324 Watts of energy. Think that's enough to fry the coils? I do. In order to limit the current to 60 mA, you have to provide enough resistance in the circuit. In our example, it would be (R = E/I) 180 volts divided by 60 mA (0.06 Amps) equals 3000 Ohms. So a 3000-Ohm resistor at, don't forget this, 180 volts times 60 mA equals a tad more than 10 watts—let's make it a 15-Watt resistor or higher to play safe—is needed.

In practice, you have to account for a variety of resistances; thus an adjustable series resistor is commonly used. A practical circuit is shown in Fig. 1. By the way, *don't* get any bright ideas about eliminating the transformer and just rectifying the ac into loop current. We don't need any hot teleprinter chassis around.

KAHANER REPORT

Larry Kahaner WB2NEL
PO Box 39103
Washington DC 20016

DIRECT BROADCAST SATELLITES: A LONG WAY TO TRAVEL

The fate of Direct Broadcast Satellites is up in the air.

Unlike low-powered satellites similar to SATCOM 1 and 2, which are mainly used to relay TV programming to cable companies owning big dishes, high-powered DBS birds aim their beams directly at smaller-dished consumers. Plans call for viewers to rent or purchase receiving gear and dishes (less than a meter in diameter) and for satellites (more than 200 Watts) to reach homes in as much as one-half of the country at the same time.

Some DBS hopefuls plan subscription TV services—in which case you must buy or rent their decoder—but others suggest that advertiser-supported programming is the way to fly. Still others say that regular video programming isn't enough to woo the public. They plan high-resolution TV and data banks for home computer hobbyists.

Although the DBS dream has been around for some time, only in the past few months has the FCC tackled the complex policy and technology issue involved in such systems. Last July, they decided to okay DBS on an interim basis pending further discussion. They also agreed to tentatively accept more than half a dozen license applications. However, no DBS applicants expect to begin full operation for another 2 to 5 years.

Some technological hurdles need to be jumped. For instance, DBS uplink frequencies are in the 17-GHz range, and downlink frequencies lie in the 12-GHz band. At those frequencies, engineers worry about attenuation from rain and fog. It seems that the higher the microwave frequency, the less you can sing in the rain.

Interference to fixed services presents another problem. Some point-to-point microwave services already use those frequencies and what effect DBS will have on their transmission (and what effect they will have on DBS) must still be explored.

However, the biggest "if" in DBS may be economic. Many figures are being bantered about, anywhere from $200 million to $800 million for a typical DBS system. If companies charge about $25 a month for the service (that's the maximum experts suggest viewers would be willing to shell out for any pay TV service), can a DBSer break even? Will consumers pay extra money for only a few additional channels when they already receive 20 or 30 on cable TV? Or would a DBS operator do better with advertising support?

The Space Shuttle might help some aspects of DBS. The most expensive part of hurling a satellite into orbit is the launch. Several DBS applicants noted that once the Shuttle is regularly whizzing back and forth in the coming years, DBS launch cost will be greatly decreased.

COMSAT checked in as the first DBS applicant, asking the Commission for permission almost a year ago to run its service. In a 1,000-page application, COMSAT'S subsidiary, Satellite Television Corporation, said it plans 3 commercial-free channels. Channel A (Superstar) will feature general entertainment such as films, concerts, and family programming. Channel B (Spectrum) will show children's programs, film classics, and public affairs. Channel C (Viewer's Choice) will offer sports, adult education, and experimental theater.

STC plans to serve the entire US with 4 geostationary satellites—one in each time zone—with spot beams aimed at Hawaii and Alaska. Each bird will carry 3 operational transponders and 3 spares. Liftoff for the first DBS satellite is slated for 1985. It would serve the east coast.

COMSAT and Sears-Roebuck planned to work together on DBS, but Sears pulled out. COMSAT is looking for a new partner but hasn't had much luck.

Another DBS entry comes from a company called Graphic Scanning Corporation. It proposes 2 satellites, each independently programmed. One satellite will target the home computer market with information relayed from the firm's information banks. Data will be sent over the video signal using

teletext, a system which compacts digital information in the vertical blanking interval of a TV's video signal. Because the home hobbyist can't talk back to the satellite and ask for information, he will have to download great quantities of data and then access what he needs and hope it's there.

GSC's other satellite offering appears mundane by comparison. It will transmit the usual TV fare including movies, sports, and concerts.

The company is serious about its application. It owns Graphnet, a computer/networking firm, and lists assets at more than $83 million.

Video Satellite Systems takes a different approach. It wants to establish an advertiser-supported DBS system with local TV stations and cable companies also receiving, then retransmitting, its programming to viewers. In a sense, it just seems to be another network, like one of the Big Three. VSS will scramble signals destined for these carriers but send unscrambled programming to those areas where consumers constitute the bulk of recipients.

VSS said its total investment will run just shy of $230 million for 4 satellites and related equipment.

Even the networks want in on DBS. CBS asked for FCC permission to operate a 3-satellite service which would send such goodies as high-resolution TV, a feed to affiliates, pay TV, and teletext. The high-resolution programming would be targeted at affiliates for rebroadcast. That assumes that we all have our hi-res TV sets by then.

Other major companies look for the go-ahead. RCA told the Commission it wants to shoot 4 satellites beyond the wild blue yonder, each carrying 6 transponders, 2 of which will sport high-resolution gear. Service will be aimed at individual homes as well as community antennas. A full system—kind of a starter service—would cost $400 million. RCA noted that DBS is economically feasible where cable services can't be provided for less than $500 per home.

The FCC received a total of 13 DBS applications. It accepted those from CBS, DBS Corporation, Graphic Scanning Corporation, RCA, Hubbard Broadcasting, Video Satellite Systems, and Western Union.

Those applicants that didn't make the FCC's grade include Advance, Inc., National Christian Network, Unitel Corporation, Satellite Development Trust, and Home Broadcast TV Partners. It partially accepted an application from Focus Broadcast Satellite, which doesn't plan its own bird but hopes to use one of the Western Union WESTAR satellites for its interim service.

Most applications weighed several pounds, contained hundreds of diagrams, charts, graphs, pictures, statistics, formulae, tables, and charts. But several consisted of only one or two typewritten pages. These, of course, were rejected by the FCC as "deficient." In other words, the DBS hopeful wasn't serious about his plan or didn't have the funds to back it up—or both. Even longer applications were rejected as deficient. Length isn't everything.

The FCC rejected applications from Home Broadcast TV Partners and Unitel for special reasons. The drafters were serving time at a federal prison near Terre Haute, Indiana.

Even if all the domestic DBS policy and technical questions are answered, international roadblocks exist. In 1983, the US will join other nations around the Regional Administrative Radio Conference table to discuss frequency allocations for microwave bands.

The FCC proposes that DBS operate in the 17- and 12-GHz range. That's fine for us, but other countries want those frequencies for their own DBS and, in some cases, for other services as well. Because we're dealing with satellites, receiving areas don't stay within neat geographical borders. DBS transmissions from abutting nations will overlap.

By the middle of the decade, about a dozen countries hope to install DBS services: Australia, Canada, China, a Consortium of European nations represented by the European Space Agency, France, Germany, Japan, Luxembourg, Switzerland, United Kingdom, the USSR, and the US.

RARC participants have a lot of talking to do.

LETTERS

ELMER: ALIVE AND WELL

Having read Tom Taorimina's letter in the November, 1981, issue, hoping for the return of Elmer, I have to admit that I agree with Wayne's response. And that ain't all that unusual.

Sure, ham radio has changed. Hell, we all have. To expect the return to the days of 6L6s, homebrew transmitters, and so forth, in this day of transmitters on a chip, is to expect better than the Second Coming.

Those moral changes that Tom said happened in the 60s: let's have them and some more. Maybe we gained a little humanity by getting off our dead ends and out of the back of the bus.

The problem is, some would have us return. Separate but equal drinking fountains. Woman at home, barefoot and pregnant. The man the undisputed ruler of the house. Child abuse. No sir, not me, Jim.

Looking back at it that way, it's obvious that Elmer isn't dead. He's alive and well, caring for humanity, like he always did. Only his areas of activity and interest have changed. Now he's into SSTV, satellite communications, cheap and easy microwave. People.

One thing's for sure about old Elmer. He doesn't sit in the sun belt and bitch about how rotten things have become. Elmer's a doer.

And he's got a million-dollar smile.

Nils R. Bull Young WB8IJN
New Carlisle OH

HAM HELP HELPED

We asked for help in your Ham Help section of *73*. Man, did we get help! In fact, we are still getting it. Really, all we asked for was a schematic or a service manual for a DSI frequency counter. Wayne, you could just not believe the response that we received from the ham fraternity when my request was published in your magazine. The response was the most impressive thing that I have ever witnessed in my 29 years of amateur radio. You may talk about the power of the press; *73 Magazine* has made a believer out of me.

I want to thank you, and all of the amateur radio fraternity who came to my rescue to help me out. In closing, I want to let you know that if I should ever need a coverage on anything related in our profession, I will most certainly rely on you and your outstanding publications.

Lawrence Neel, Jr. W8PKV
Cincinnati OH

LIP BITING

You can thank or blame your October "Never Say Die" for this letter. That editorial started with a caption which stimulated this reader to give you one old-timer's view of the other side of the coin. It happens that I have been in ham radio since 1929... have written for **CQ**, **QST**, ***Radio Electronics***, ***Popular Electronics***, and ***Electronics***...have also lectured at hamfests and an IRE convention. Like you, I witnessed and contributed to the growth and popularity of ham radio. Then, due to a new assignment and the pressure of making a living, I dropped out of the fraternity and did not return until after my retirement. Wow!

I missed the multimillion-dollar explosion that was brought about by SSB and the consequent sale of a million or so transceivers and supplementary gear by your advertisers...an era which also resulted in a many-fold increase in the cost of operating a station... an era which also imposed a severe hardship on any prospective newcomer to the hobby. Then along came CB...and that was the straw that broke the camel's back.

So you want to know what is needed to reactivate ham radio? Well...bite your lip and hold on to your temper...what we don't need is a rich man's elongated

legeo writers on now to build sophisticated and digitalized electronic equipment using lots of integrated circuit devices, which few of us comprehend. Too bad the authors and publishers don't have to stand up in front of an audience for a Q&A session... talk about red faces!

Don't go away now... the pièce de résistance is coming up. Of all the things we surely don't want, your continued writing about your activities in the computer field have to be near the top of the list. Did you ever stop to consider that such writings tend to convince us that your heart and personal interests and *ambitions are far* removed from our beloved ham radio field?

Now then, if you have indulged me this far, stick around for a few more minutes. I'm about to say something nice. Once in awhile, you publish an article which is down-to-earth and of genuine interest to a sizable percentage of us hams. Let me cite the "Diode Doctor" article which appeared on page 131 in your October issue. Too bad the editors allowed the author to make use of a 9-volt battery which had *two* positive terminals and *no* negative terminal. Sure, we inferior hams can figure out the error, but we can also figure on similar errors being in projects that take longer than "about 15 minutes" to build.

By the way, if you are getting the idea that I am an unfriendly correspondent, please refer to your July, 1981, issue, "Fun," page 140, second column, last paragraph. I am one of your staunchest boosters. Nevertheless, I believe you have drifted away from your own publication. Of course, I can only judge by my own experience, but I can't believe your people could possibly single me out for careless treatment. Like the way your Subscription Department loused up my subscription... missed sending me the first issue as specified in your advertisement... then sent me two copies of a subsequent issue rather than the one I expected to get... then kept insisting that I did not pay for my subscription until I got my cancelled check from the bank and gave them the number and date and data.

I started out 1981 by writing an article for *73* entitled "The Jim-Bug." It was promptly accepted. A check followed a few months later. But now is many months later, and I have still not received a proof for review. You must agree that is no way to make friends and encourage more articles. If they have changed their minds, why don't they say so and send the article back to me?

Well, I have now given you over three hours of my time in composing and typing this letter, but I don't want to end it on a negative tone. So I'll put forth some more effort on the subject of promoting the growth of ham radio. To do this, we first have to realize that most of the active hams, who regularly have to fight QRM for enjoyment of their hobby, do not favor additional growth. Second, we have to find ways to get prospective newcomers into the fraternity without mortgaging their homes. This means making available simplified and lower-cost equipment, home-built, kits, or manufactured. Third, we have to provide air space and regulations where such equipment can be used. Fortunately, the air space has already been made available in the new bands... bands which many of us old-timers don't want and can't use. So why not leave it up to the League? Because if we do, we are going to get more of the same SOS.

Jim Owens W5JOF

"...a station" is another tune I've heard often... but not from anyone who was there before. I ask you to recall the cheap and junky Hallicrafters Sky Buddy receiver which sold for $29.95 in 1938. Today, for about the equivalent inflation-adjusted price of that old crummy receiver, you can buy an allband receiver that will run circles around that old one. Hams have never had it so good as far as equipment prices are concerned.

I did enjoy the "rich man" bit, too. Jim, I started out with nothing and worked hard to build up my business. When I started 73, at times I didn't have enough money to eat but I hung in there and worked 100-hour weeks... and more. My recent trip to Africa cost me little... it was paid for by the people who came to hear me talk in Johannesburg. They paid to hear me because I have taken the time and interest to know my field and be worth listening to when it comes to computers... something I've managed to learn in just the last five years. And Jim, talking with foreign countries is one of the basics of amateur radio, so I've always found hams intensely interested in what is really going on in them... in particular, the rare ones.

Okay, now I'm to the bit about building sophisticated digital electronics. Our recent reader poll gave us an 82% reader vote on our articles being about right, 7% said they were too simple, and 11%, too complex. I don't think we could run the ball any closer to the center of the alley.

With computers and amateur radio coming together on a collision course, I've found that most amateurs want to know all they can about them. I asked for a show of hands at a recent ham club meeting and almost half of those present said they already had a computer. Actually, only about 20% of the active hams have a computer system so far... but that is increasing rapidly.

Jim, with about 90% of our income coming from computers, it would make just plain sense if I gave amateur radio no more than 10% of my time. But I now find myself as the chairman of an FCC subcommittee to get amateur radio into a growth mode, which will take time I could ill afford if plain making money were all that important. You may find many hams who are spending more time enjoying the benefits of amateur radio, but I wonder how many you'll find who are investing their time as much as I am, and also a few others of NIAC, in the future of our hobby?

Now, on that article. I hope a few readers look it up and explain it to you. There is nothing at all wrong with it. The battery goes between the plus and ground terminals.

The subscription department is far from perfect... but it is one of the best in the country. It is a commercial service and our complaints are a tiny fraction of what we've had in the past. They are also incredibly expensive.

Articles are bought for the purpose of publishing. It can take up to a year or more, if an article is not one of strong time value, before it is published. It'll be along.

Many old-time hams, rather than cope with new narrower band techniques, are pushing to stop ham growth instead. Some may still be around muttering "spark forever" under their breath. Jim, we will develop new modes of communications and we will grow... a lot... or we will die.

May I respectfully also point out that while it is possible to find ham bands which are packed, we also have a bunch of others where there is no crowding. Perhaps, if you could march to a slightly different drummer, you might enjoy interference-free contacts. Much of 10, 6, 2, and upward are quite open. Even 15 is seldom filled up... if ever. So why go the lemming route and insist on adding one more bit of noise to the few jammed-up frequencies?—Wayne.

MONEY GRUBBING?

I find little of interest in *73*. My interests are mainly in the technical or project end, and I find that much of this sort of thing is either not present or of no interest. Probably the most important single project these days would have to be low-voltage, high-current power supplies of up to 500 Watts. When was the last time you ran a good article on such as this? Some time ago you used to run useful articles on computer interfaces with ham radio. Then you started some computer mags and, of course, then tunneled all these

into the computer publications. But, now, lo and behold, you are a big honcho in the Instant Software market place and appear reluctant to put anything in *80 Micro* that you might be able to flog through Instant Software. Very subtle!

All that aside as a fairly typical money-grubbing ploy, frankly, your attitude to ham radio scares the pants off me. You come out in favour of people being able to buy copies of the examinations, you are against nets, you deplore the fact that anyone wants to remove the certifiably insane from the air, you want to increase the ham population of the States by some 200,000.

Take a look at the two *Callbooks* side by side. There are already more hams in the States than all the rest of the world put together. Your examinations are a joke in many parts of the world. There are probably more lids in the W4/5 district than the whole of the rest of the world. It is almost impossible to do anything organized on the air without having someone deliberately interfere. I suppose you would consider this an infringement of civil rights to restrict these activities! Now you want to get the rest of the "Criminal Band" fraternity on the air. Nice for circulation. Must make you drool!

I clawed my way up to number two on the ARRL Public Service Honor Roll until I quit in disgust when it finally dawned on me that the ARRL did not in fact represent the interests of the amateur but rather the interests of the executives and staff at Newington.

While I sometimes thought your articles on the ARRL were a bit overstated, in general I agreed. Now I am beginning to find some frightening similarities. Would success and fame go to Green's head?

A. E. M. Spence VE7DKY
Vernon BC
Canada

AEM...phooey...and I'll tell you why. There you are carping at someone who is getting things done and moving the world ahead a bit, with your contribution one of having "clawed" your way up to number two on the ARRL Public Service Honor Roll. Well, whoo de doo. Lookie here. I resent your insinuation that I'm money-grubbing. Oh, I'd like to be, but I keep thinking of more projects and whoosh, away goes the grubbed money.

I did enjoy the bit about Instant Software getting the good 80 programs. If you could hear the beefing I have laid on everyone around here, just trying to get the Instant Software people to even look at a copy of the magazines to see if any of the programs we have published might be worthwhile to distribute, you'd know what I mean. I've tried to get ISI to let the magazines take a look at their losers for possible publication. I think we are making headway there, but only recently. No, you're full of it as far as that one is concerned.

Please let me know where you got the idea I'm against nets. Having called into 'em for years, that's a new charge. Matter of fact, one of the services we're planning for the W2NSD/1 bulletin board is a net listing. And the Bash Cheatos? Well, by refusing to run ads for the Bash "guides," we're passing up perhaps $15,000 a year in advertising, so what do you want from me? I do think that his "study guides" and the ARRL Q&A Manuals have provided the cheats the easy way to get a license for as long as I can remember. My license study manuals are not that kind...they teach the theory. You're all wet again.

The Callbook? *How can you be so off base on* everything? *They don't list about 90% or more of the Japanese hams... or about 90% of the Russians...and a lot of other foreign hams. If they did, no one would buy the book...it would look like the Manhattan yellow pages...and cost a fortune.*

And you're after the CBers too. For your information, sir, about 90% of the US hams licensed in the last ten years started out on CB. Bad operating is not really new...just ask any old-timer. Spence, I was there 50 years ago, so I know what it was like then. I've been active ever since. If you want to know about deliberate interference, just read the editorials in the 1920 and 1930 issues of QST. Nothing has changed... it's just that you have no perspective and you, for some odd reason, think things were better. They weren't. The next thing you'll be beefing about is that people don't build anymore. Well they do...and more than they did 50 years ago.

Will success go to my head? Probably. I do admit to enjoying it, mostly because as a recognized success I am able to get much more done. My ideas now are able to reach people and, in view of my success, be taken seriously. Would you want to read a book on how to make a million dollars written by someone on welfare?

Power supplies? Lordy, we've published so many power supply articles in 73 that another publisher has taken them and published a book on the subject.

My interest is not to increase the ham population of the United States by 200,000...in which you are consistent in your inaccuracies...it is to lift it to 2,000,000. Why be chintzy?—Wayne.

COMBATTING RADAR

I have recently learned that the State of Wisconsin is in the act of passing a new law outlawing radar detectors. It will be a $200 fine if you are caught using a radar detector.

Does anyone out there know if the various radar detector companies are willing to go in to try to overturn this law in state court, or at least help someone who wants to? I think it is a crime if they are about to outlaw receiving *any* type of radio transmission, including radar. If anyone knows how to combat these kinds of laws, or how to go about overturning them, or if they have gone through this kind of thing already, please write Ken Slate W9ITW, 427 Hamburg Street, Ripon WI 54971.

Kenneth H. Slate, W9ITW
Ripon WI

HAM VERSUS CABLE TV

I noticed a letter in your September issue regarding CATV 2-meter interference. I was a CATV technician in charge of quality control at a large northeastern system for over six years and would like to take this opportunity to discuss this problem.

FCC rules pertaining to radiation from CATV currently state that between 54 and 216 MHz, radiation shall be not more than 20 μV/m at a distance of three meters. Above and below that frequency range, the level is 15 μV/m at 30 meters. They further state that should interference to another duly-licensed service occur, radiation must be reduced to the point where no interference occurs regardless of levels involved.

Under the present technology and methodology employed by conscientious CATV systems, it is all but impossible to locate radiation below about 14 μV/m at three meters. The problem is that the typical 144-MHz rig has a sensitivity of less than 1 μV for 10-dB quieting; near-field radiation is more an inverse linear function than inverse square, so interference is bound to occur in a metropolitan area.

From my experiences, the main trouble spot appears to be 145.25 MHz which is both CATV channel E and a repeater frequency. The following are possible solutions, in no particular order of feasibility.

1) Do not assign this frequency to a repeater.

2) The cable TV company can offset channel E by plus or minus 10 kHz. These are standard offsets. Probably a greater offset would help.

3) The cable company could use a harmonically-related carrier headend.

4) The repeater frequency could be offset. Probably 10 to 25 kHz should suffice.

5) Hams in areas not present-

ly cabled should keep informed about any CATV activity in their vicinity. Offsetting or using a harmonically-related carrier headend are decisions to be made preferably before activation of a system.

There are many hams in the technical side of CATV who can help and management types are usually pretty open-minded. With the proper attitude, maybe both sides can solve the problem once and for all.

Robert Wanderer WB2MCB
Herzliyya, Israel

Wouldn't it be great if all cable operators shared WB2CMB's open-minded, conscientious attitude? Unfortunately, many CATV companies are reluctant to upset the apple cart, much less spend any money that would result in a reduction of short-term profits.

The idea of a legitimate amateur repeater shifting its frequency to accommodate CATV does not appeal to me. It is just another form of spectrum robbery. Offsetting the cable channel and insisting on a well-shielded system should go a long way towards reducing the problem.

A firm but tactful approach seems to be in order. If the cable operator refuses to cooperate, perhaps some high-power transmissions on or about 145.25 MHz will prompt action.—Tim Daniel N8RK.

TAKE US ALONG

I want to tell you how much I enjoyed Wayne's description of the St. Lucia trip and the fine article by Jeff DeTray, "Contesting from VP5," with more Turks and Caicos adventure. Thanks for taking us along via the article and "Never Say Die." Let's have more satellite and MDS articles.

DXPEDITION HELP

DXpeditions International was formed by a small group of DXers who desire to help DXpeditions to the more rare DXCC countries. In order to meet this goal, the DXpedition Fund was established and shall remain on deposit until a significant contribution can be forwarded to a deserving DXpedition. At the present time, the DXpedition Fund is small, and outside membership and participation is paramount to its success. The DXpedition Fund's assets are on deposit at the Fulton Federal Savings and Loan in Waycross, Georgia. Interest paid on this deposit is returned to the fund. As the fund grows, more assistance will be rendered to DXpeditions which otherwise may not "Make The Trip."

Individuals or clubs may request assistance for their DXpedition by writing to DX Review Committee, DXpeditions International, 999 Wildwood Road, Waycross GA 31501. This request should include the plans and details of the proposed DXpedition. A business-size SASE would also be appreciated. (As you can see, we desire to keep costs down, thus providing more assistance to a DXpedition.)

Before the DX Review Committee can make a final commitment for funds, the DXpedition organizers must meet some strict criteria. The complete list of criteria will be forwarded to those who request our assistance, but for example, they include the following:

1) The DXpedition must have in hand the licenses or permits required for operation from the proposed DXpedition location.

2) DXpedition members must have the appropriate passports, visas, and other documents required for entrance into the country or locality from which they will operate.

3) DXpedition organizers must furnish a financial statement of DXpedition funds on hand and a complete cost analysis for the DXpedition.

When the DX Review Committee rejects an application for failure to meet requirements, the applicant may reapply at such time the criteria can be met. The amount of assistance will be determined by the assets of The DXpedition Fund, the needs of the DXpedition organizers, and the rareness of the country of proposed operation.

The organizers of DXpeditions International and their families *are not eligible* to receive assistance from the DXpedition Fund, but those holding memberships in the organization, either full or limited, shall receive priority consideration when applying for assistance for their DXpeditions.

In order to keep the membership of DXpeditions International informed, a newsletter is printed on a weekly basis. This newsletter is mailed to all members and is devoted to the news and operations of DXpeditions and other DX as may be "On The Bands." Membership categories are:

1) Full Member—Receives the DXpeditions International newsletter and also makes a significant contribution to the DXpedition Fund. (US $38 fee.)

2) Limited Member—Receives the newsletter but does not make any contribution to the DXpedition Fund. (US $28 fee.)

3) Friend—Our Friends are not members of DXpeditions International but are individuals who desire to make some contribution to the DXpedition Fund. The size of the contribution varies from Friend to Friend, but the entire amount is deposited into the fund.

DXpeditions International hopes that it can make a marked contribution to the amateur radio fraternity and to DXing. With your help and participation, this goal will be met.

DXpeditions International

JERRY AND DXCC

This is the real K2RA, and unfortunately for me my K2RA call has been bootlegged on the air by some culprit named Jerry since 1978, mostly in contests and on the 20- and 10-meter SSB bands. His location is unknown.

This guy Jerry is using up all of my envelope credits at the North Jersey DX Association QSL Bureau, and that's how I found out about him. I have enough DX cards confirming his contacts made with my K2RA call for me to get DXCC! I have notified the ARRL and the FCC. Jerry can pick up most of his cards with my callsign at this address (except for the ones I sent to the FCC). I will be glad to meet him.

HAM HELP

In order to repair my Hallicrafters receiver, model SX 122, I must find a schematic diagram and my problem is that I can't even find Hallicrafters in the States let alone the schematic.

A tag on the receiver shows it was made in Chicago but the Embassy here has no Chicago address. What to do? Has it gone out of business?

Any help will be greatly appreciated indeed.

NEW PRODUCTS FROM HAL-TRONIX

2304 MHz DOWNCONVERTERS

Frequency Range 2000–2500 MHz

2304 Model 1: Basic three-stage, less case and connectors **$49.95**

2304 Model 2: Three-stage, includes preamp, with die-cast case and connectors **$59.95**

2304 Model 3: With high-gain preamp, die-cast case and connectors **$69.95**

The above models complete with high-quality drilled PC boards, all electronic components, etc., with 15-page manual.

Note: Any of the above, factory wired, $50 additional

POWER SUPPLIES FOR THE DOWNCONVERTERS:

- Power supply kit #1, less case and connectors **$19.95**
- Power supply kit #2, includes case & connectors **$24.95**
- Power supply—already built, complete **$34.95**

PARTS FOR THE NTSC RF MODULATOR FOR CHANNELS 3, 4, or 5. This is **not** a complete kit. The hard-to-get parts include the LM-1889, the .08 microhenry tank coil, the 7-14 microhenry adjustable coil, the 10 microhenry RF coil, with schematic (no PC board) as used in Bob Cooper's satellite TV receiver. Real buy at **$5.95**

TOUCHTONE DECODER KITS

HAL 567-12: single line in, 12 lines out, complete with 2-sided plated-through G-10 board and all components. Uses seven 567's and three 7402's **$39.95**

HAL 567-16: single line in, 16 lines out, complete with 2-sided plated-through G-10 board and all components; includes 22-pin edge connector. Uses eight 567's and four 7402's. (See construction article in April 1981 Radio & Electronics for complete writeup.) **$69.95**

TOUCHTONE ENCODER KITS

HAL ECD-12: 3×4 twelve-character encoder utilizing the ICM 7206 Intersil chip. Kit comes complete with both LED and audio-coupled outputs (speaker included). With aluminum anodized case **$29.95**

HAL ECD-16: 4×4 sixteen-character encoder utilizing the ICM 7206 Intersil chip. Kit comes complete with LED and audio-coupled outputs (speaker included). With aluminum anodized case **$39.95**

New England's Distributor and Authorized Service Center for all Major Amateur Lines. **Tufts Radio Electronics, Inc., 61 Lowell Road, Hudson NH 03051, 883-5005.**

Ann Arbor MI

See us for products like Ten-Tec, R. L. Drake, Dentron and many more. Open Monday through Saturday, 0830 to 1730. WB8VGR, WB8UXO, WD8OKN and W8RP behind the counter. **Purchase Radio Supply, 327 E. Hoover Ave., Ann Arbor MI 48104, 668-8696.**

Charlotte NC

Santec, Hy-Gain, Cubic Comm., Antenna Specialists, Wilson, W2AU/W2VS, B&W, Pathcom, Nye Viking, Electra, MFJ, Bash, CQ, Arrl., Ameco, Callbook Service, Sales New & Refurbished. **Home-Tronics, 1217 Plaza, Charlotte NC 28205, 334-7974.**

Somerset NJ

New Jersey's only factory-authorized ICOM and YAESU distributor. Large inventory of new and used specials. Most major brands in stock. Complete service and facilities. **Radios Unlimited, 1760 Easton Avenue, P.O. Box 347, Somerset NJ 08873, 469-4599.**

Amsterdam NY
UPSTATE NEW YORK

Kenwood, ICOM, Drake, plus many other lines. Amateur Dealer for over 35 years. **Adirondack Radio Supply, Inc., 185 West Main Street, Amsterdam NY 12010, 842-8350.**

Central NY

Amateur radio hardwood displays made to your specifications—callsigns, plaques, awards or special orders. High quality, fast service, low prices. **A.&M. Woodcraft, 313 N. Madison St., P.O. Box 243, Rome NY 13440, 337-5642.**

Syracuse–Rome–Utica NY

Featuring: Kenwood, Yaesu, ICOM, Drake, Ten-Tec, Swan, DenTron, Alpha, Robot, MFJ, Tempo, Astron, KLM, Hy Gain, Mosley, Larsen, Cushcraft, Hustler, Mini Products. You won't be disappointed with equipment/service. **Radio World, Oneida County Airport-Terminal Building, Oriskany NY 13424, 337-0203.**

Columbus OH

The biggest and best Ham Store in the midwest featuring quality Kenwood products with working displays. We sell only the best. Authorized Kenwood Service. **Universal Amateur Radio Inc., 1280 Aida Dr., Reynoldsburg (Columbus) OH 43068, 866-4267.**

Scranton PA

ICOM, Bird, CushCraft, Beckman, Fluke, Larsen, Hustler, Antenna Specialists, Astron, Avanti, Belden, W2AU/W2VS, CDE, AEA, Vibroplex, Ham-Key, CES, Amphenol, Sony, Fanon/Courier, B&W, Ameco, Shure. **LaRue Electronics, 1112 Grandview St., Scranton PA 18509, 343-2124.**

Houston TX

Experimenter's paradise! Electronic and mechanical components for computer people, audio people, hams, robot builders, experimenters. Open six days a week. **Gateway Electronics Inc., 8932 Clarkcrest, Houston TX 77063, 978-6575.**

San Antonio TX

Complete 2 way service shop. Call Dee, W5FSP. Selling Antenna Specialists, Avanti, Azden, Bird, Hy-gain, Standard, Vibroplex, Midland, Henry, CushCraft, Dielectric, Hustler, ICOM, MFJ, Nye, Shure, Cubic, Tempo, Ten-Tec and others. **Appliance & Equipment Co., Inc., 2317 Vance Jackson Road, San Antonio TX 78213, 734-7793.**

Vienna VA

The Washington metropolitan area's leading supplier of the latest in Amateur Radio and Test Equipment. On your next trip to the Nation's Capital, stop by and see us. **Electronic Equipment Bank, Inc., 516 Mill St. N.E., Vienna VA 22180, 938-3350.**

Casper WY

Serving Wyoming Hams with lots of good stuff like Callbook, antenna parts, specials and bargains. Willy and Larry Dean invite you to drop in anytime. **Radio Activity, 531 W. Collins Dr., Casper WY 82601, 237-5248.**

DEALERS

Your company name and message can contain up to 25 words for as little as $150 yearly (prepaid), or $15 per month (prepaid quarterly). No mention of mail-order business or area code permitted. Directory text and payment must reach us 60 days in advance of publication. For example, advertising for the March '82 issue must be in our hands by January 1st. Mail to 73 Magazine, Peterborough NH 03458. ATTN: Nancy Ciampa.

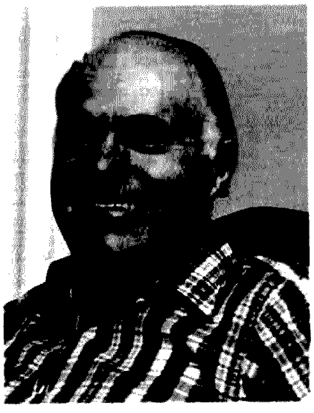
W2NSD/1 NEVER SAY DIE

editorial by Wayne Green



NOW, THE GOOD NEWS

The easy passage of the Goldwater ham bill through the Senate was certainly good news... and will bring closer some badly needed changes in the fundamental rules by which the FCC has had to operate.

Another bright spot was a bill entered in the House (in November) by Rep. Timothy Wirth of Colorado. Let me give you quotes on some of the provisions of this bill...

Authorize use of amateur volunteers for examination preparation

Section 4(f) is amended by adding at the end thereof the following new subsections:

"4(f)(4) Notwithstanding the provisions of Part III of Title 5, United States Code or 31 U.S.C. §665(b), for purposes of administering any exam-tion for an amateur station operator license, the Commission may accept and employ the voluntary and uncompensated services of any individual who holds an amateur station operator license of an equal or higher class than the class license for which the examination is being prepared. Any person who provides services under this paragraph shall not be considered, by reason of having provided such services, a Federal employee for any purpose."

Explanation

This proposal would provide a statutory basis for present practice at the Commission, and would allow expansion in the Commission's use of volunteers. The amendment would have no discernible effect on our budgetary requirements.

"4(f)(5) Notwithstanding the provisions of Part III of Title 5, United States Code or 31 U.S.C. §665(b), for purposes of administering any examination for any amateur station operator license, the Commission may accept and employ the voluntary and uncompensated services of any individual who holds an amateur station operator license of an equal or higher class than the class license for which the examination is being conducted. Any person who provides voluntary and uncompensated services under this paragraph shall not be considered, by reason of having provided such services, a Federal employee for any purpose."

Explanation

The present practice of the Commission is to permit volunteer licensees holding an Amateur Extra, Advanced, or General Class license who are at least 18 years of age to administer Novice Class operator license examinations. The proposed amendment would give statutory recognition to this practice and would allow the Commission to extend the practice to examinations for other classes, at the discretion of the Commission.

This program would help to conserve Commission resources and additional benefits would result from the fact that applicants would likely be able to take examinations within their communities, as opposed to having to travel to FCC field offices for testing.

Once the FCC has been authorized to let amateurs prepare and administer exams, we have the path open to set up a system whereby certain clubs might be able to hold classes to teach the needed theory, rules, and operation skills to prospective hams... followed by oral exams and a demonstration of skills.

While there are some amateurs who believe that the tension and panic of an FCC-administered exam are beneficial in some way, that was not my experience... nor the experience of anyone I've talked with about it. There seems to be a general concept that we should do everything possible to keep enthusiastic people out of the hobby rather than doing all we can to interest people in it... and making their entry an enjoyable experience.

There seems to be some wariness that we will suddenly find ourselves with a system where we are bringing in people who will be rotten hams and thus spoil the hobby. I would say two things to those worriers... first, we already have a fine system for bringing in lousy hams, one which has been working with a high degree of perfection. One has only to visit Los Angeles to get the full flavor of the 1980s-type ham in full bloom. It should be obvious that the present system of filtering out the weirdos is not working worth beans.

Secondly, I know of no one interested in opening the flood gates to CBers to come into amateur radio for a free ride. Not even CBers have suggested anything that preposterous. I do hear hams opposing it, but these chaps are merely fighting their own straw man, not anything ever seriously proposed. If some hams are gullible enough to get excited over such ma-

$$ HOME-BREW CONTEST $$

For some of us, there is no more satisfying experience than designing and building a piece of electronic gear. Now there's a chance for you home-brewers to receive special recognition for your achievements. It's the *73 Magazine* Home-Brew Contest.

Between now and April 1, we'll be looking for articles describing the best home-brew projects in the land for under $100. All useful projects will be published in *73*, and the cream of the crop will share $500 in cash prizes. Top prize in the contest is $250, with $100 going to the second place project and $50 to each of three honorable mentions. These prizes are over and above the payment that all authors receive for having their articles published in *73*.

Contest Rules

1. All entries must be received by April 1, 1982. To enter, write an article describing your best home-brew construction project, and submit the article to *73 Magazine*. Any construction article received before the April 1 deadline is automatically entered in the contest. If you haven't written for *73* before, please send an SASE for a copy of our author's guide.
2. The total cost of the project must not exceed $100, even if all parts are puchased new. Be sure to include a detailed parts list, with prices.
3. All parts used in the project must be available to the average radio amateur or electronics experimenter. To be on the safe side, include sources for any unusual components.
4. Projects will be judged by the *73* technical staff on the basis of usefulness, reproducibility, economy of design, and clarity of presentation. The decision of the judges is final.
5. All projects must be original, i.e., not previously published elsewhere.
6. All rights to articles purchased for publication become the property of *73 Magazine*.

Send your entries to:

Home-Brew Contest
73 Magazine
80 Pine Street
Peterborough NH 03458

Winners will be announced in the June, 1982, issue of *73*. Have fun!

neuvers, then we should consider them part of the problem, not part of any solutions.

No, I think it is plain to just everyone that our present licensing system stinks. Here we have a Morse code test which a four-year old has passed with flying colors. . . big deal filter. We have a technical exam that few people even bother to study for. . . why bother when you can buy the test answers from Bash and just memorize the answers? That includes questions on rules, so we don't even have to know them anymore. It is no wonder that we have jamming of repeaters, foul language on the bands, stupid pileups of DX stations, and a situation on two meters in Los Angeles that has to be heard to be believed.

Not only are things going to hell in a basket, but we have the spectacle of thousands of hams doing all they can to protect this terrible system and make sure that we get even more of the same kind of hams.

Yes, I do have some ideas on what to do about the situation. And I think they will work. They certainly are right up the alley of the current FCC changes. The Commission has two major interests these days. . . deregulation and cutting expenses. I think that we can take advantage of these and at the same time improve amateur radio substantially.

Let's take a look at some basics. Firstly, yes. . . we do have some terrible hams in our ranks. But we recognize that, as much of a pain in the ass as these bums are, they are a distinct minority. Okay. . . there's a hint for us. . . a clue on how to start getting out of this miserable situation.

To me, one of the foundations of amateur radio is the ham club. I believe that every ham should belong to and support a ham club. This is one of the big strengths we have. This also is a key to our separating the good from the bad and the ugly, for few of the really bad eggs ever join clubs. The same behavior which makes them despicable on the air keeps them from having friends off the air. And what few do have the guts to come to club meetings, knowing what others think of them, are not thought well of for it. Thus, I suspect that the more we can involve our clubs in the training and licensing of newcomers, the better class of hams we will have on our bands. Perhaps we could even consider some sort of trial period for newcomers before their licenses are permanent so that we could observe them on the air.

We already know that the most vicious and obnoxious of people are quite capable of learning the code. In fact, since some of the worst hams we have had have been Extra class, perhaps there is some correlation between ugliness and adaptability to code (I'm kidding. . . aren't I?). I think that CW is one of the most treasured aspects of amateur radio, but I also think that the ability to copy the code is meaningless as far as determining whether someone is going to be a good ham. I think that once we make code ability honorable and stop forcing people to learn it for the test, we will take a lot more pride in it. Who can really take pride in something which he has to do, whether he wants to or not?

Clubs are an answer to many of our problems. If we are going to get amateur radio into any serious growth pattern we are going to have to have many more and stronger ham clubs. I would like to see ham clubs set up in every high school in the country. I'd like to know that every ham club has classes to teach newcomers the theory, the rules, and how to operate. If the Wirth bill goes through, it will open the way for clubs not only to teach the fundamentals of amateur radio, but also to make up and administer the exams. Talk about a service being self-sustaining!

This also would cut the cost to the FCC substantially. I don't know how much they are paying their people to keep writing new test questions to try to stay ahead of Bash and his cheat-sheets, but it must be a substantial amount. Then there is the cost of printing and distributing the tests. If the field personnel of the Commission did not have to sit around and administer exams they would be freed up for more productive work. . . or even to go into the private sector and earn money for taxes instead of spending it. We sure have a need for engineers and technicians these days in industry. . . a desperate need.

Monitoring

Another provision of the Wirth bill is as follows. . . .

Authorize use of amateur volunteers for monitoring

"4(f)(6) For purposes of monitoring any violation of any provision of this Act, and of any regulation made by the Commission pursuant to this Act, relating to the amateur radio service, the Commission, notwithstanding any provisions of Part III of Title 5, United States Code or 31 U.S.C. § 665(b), may (I) recruit and train any individual licensed by the Commission to operate an amateur station; and (II) accept and employ the voluntary and uncompensated services of such individual. For purposes of recruiting and training such individual, the Commission may also accept and employ the voluntary and uncompensated services of any amateur station operator organization. Any person who provides voluntary and uncompensated services under this paragraph shall not be considered, by reason of having provided such services, a Federal employee for any purpose."

Explanation

The volunteers' monitoring authority should include the monitoring of amateur licensees transmitting on frequencies not assigned to the service and is intended to permit volunteers to collect violation reports and annotate and summarize them for the convenience of the FCC.

Enactment of this proposal would enhance the Commission's enforcement efforts and bolster efforts to detect and prosecute rule violators. To ensure that a volunteer monitoring program helps rather than hinders the enforcement program, it is important that violation reports undergo preliminary review by volunteer organizations to help FCC personnel determine which alleged violations represent the most promising targets for the Commission's limited enforcement resources.

This amendment would not increase our budgetary requirements. It may help us to conserve our enforcement resources or, at least, improve the efficiency of our enforcement program.

If the Commission is to fully utilize the services of volunteer amateur licensees for monitoring, as envisioned by this proposal, there should be *an exception to Section 605 to permit the monitoring groups to receive and disclose information transmitted by amateur licensees and operators (See proposed amendment to Section 605, infra.)*

Exempt amateur radio communications under certain circumstances

Section 605 is amended by striking the last sentence thereof and adding the following:

The Fun-Oscillator

—a simple, goof-proof vfo for your QRP transmitter

Note: A complete kit of parts, including PC board, is available from RADIOKIT, Box 411S, Greenville NH 03048 for $34.95 plus $2.50 shipping and handling.

The Fun-Mitter (February, 1981, *73*) and Fun-Ceiver (July, 1981, *73*) provided the home-brew-oriented amateur with the basic components for a home-brew station setup.

Many amateurs have responded by saying that they need more frequency flexibility for their Fun-Mitters.

The simple vfo described in this article is the result of those requests. It allows greater frequency excursions than the simple vxo circuit of the Fun-Mitter to provide approximately the same frequency coverage as the companion receiver. The vfo follows the same guidelines as the two previous articles and should be as easy (or easier) to construct and to get operational.

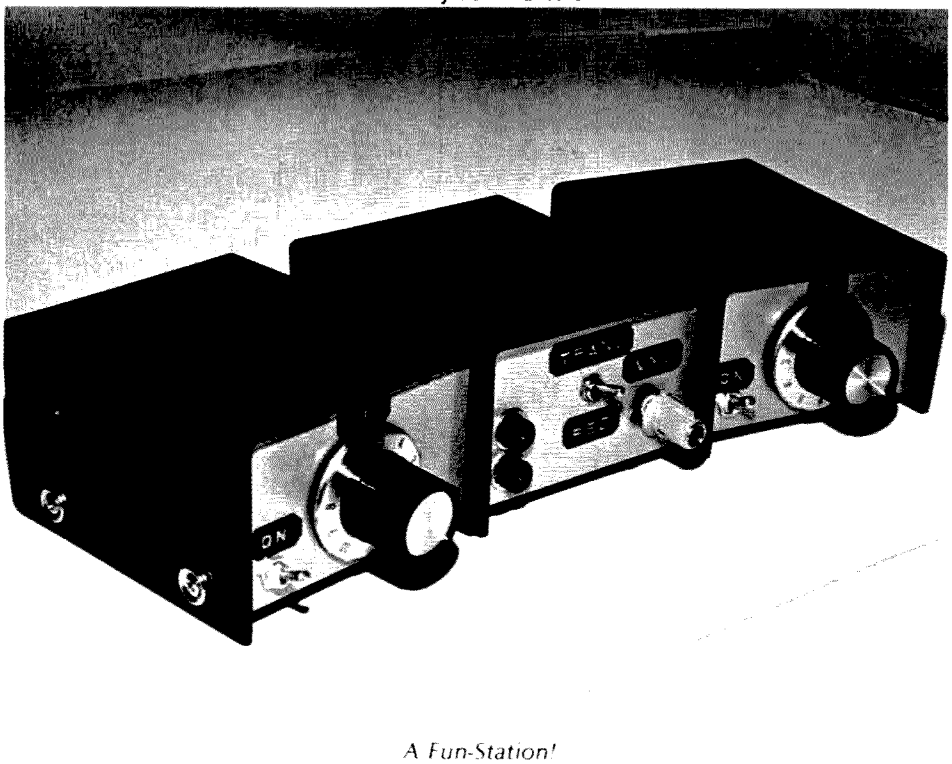
For those unfamiliar with my earlier articles, this series of articles focuses on simple, easy-to-construct, easy-to-operate gear with all parts available from local Radio Shack outlets. Size and appearance of the vfo match the transmitter and receiver to provide a nice looking station package.

Of utmost importance is the fact that no modifications have to be made to the Fun-Mitter to use the vfo. It simply plugs in where the crystal was (unless C_{opt} was installed). This allows for either crystal or vfo operation of the Fun-Mitter. Also, it can be constructed for either 40 or 80 meters. It provides about 70 kHz of coverage on 40 meters and about 50 kHz on 80.

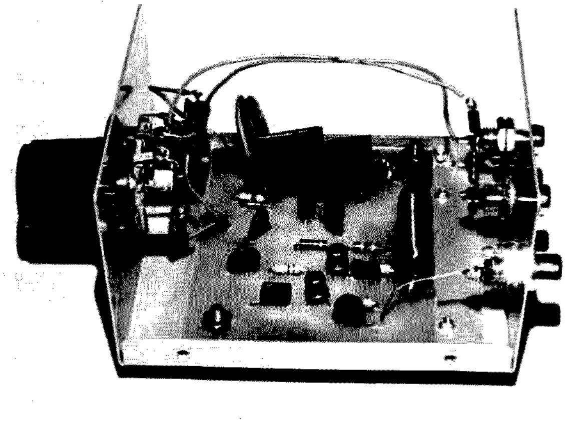
The Circuit

The vfo should be the most goof-proof of all three pieces of gear as evidenced by the schematic of Fig. 1. The basic frequency-determining portion of the vfo is identical to the vfo of the

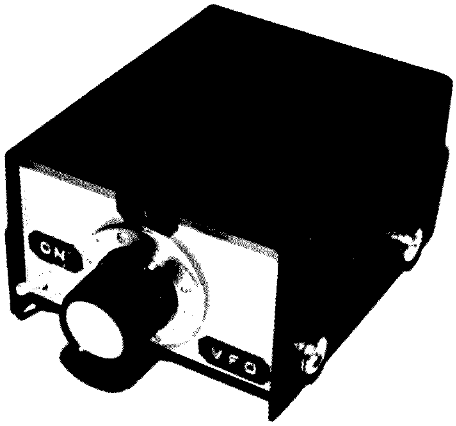
Photos by Duane Bertsch



A Fun-Station!



Internal view of vfo.



Front view of the completed Variable Fun-Oscillator.

Fun-Ceiver. This allows for ease of understanding and construction as well as similar frequency range.

Before I began this series, I developed a set of guidelines for the items to be designed. Based on this criterion of setting goals in advance, I developed the following goals for the simple vfo.

- Good performance (no chirp, minimal draft, clean waveform)
- Simple construction (PC board use, less than four hours total build time, minimum parts count)
- Cost—less than $20 with new parts
- Minimal modification to the Fun-Mitter
- Full output from the Fun-Mitter
- No variable capacitors or inductors

The final version of the vfo meets the above goals.

Only three transistors are used in the vfo, one as the oscillator (Q1), one as a class-A amplifier (Q2), and one as an emitter-follower buffer (Q3). This final version of the vfo went through three revisions from the original form. This was necessary to maintain good performance while still keeping things simple. The original design included only two transistors, but at times chirp was detected on the transmitted signal. The main advantage of the circuit of Fig. 1 is that only one tuned circuit is used (L1). This means modifying only one inductor!

Q1 operates as a parallel-tuned Colpitts oscillator with L1, CR1, CR2, C1, C2, and C3 being the frequency-determining components. The oscillator is tuned by varying the voltage at the junction of the two diodes. This, in turn, varies the capacitance of the diodes which varies the frequency of the oscillator. L1 is a modified Radio Shack 10-μH rf choke. It is modified, as described later, to provide the needed inductance. The last few turns of the modified choke are spread out over the choke body to provide an easy means of setting the oscillator frequency.

As mentioned in the receiver article, the capacitors needed to build a stable vfo are not easily found at Radio Shack. NPO-type capacitors from a large variety pack again are used in parallel and series combinations to obtain the needed capacitance for C1, C2, and C3. Silver-mica or polystyrene capacitors will give even better results.

Output from Q1 is taken through a coupling capacitor, C4. This capacitor should be kept as small as possible to isolate the oscillator from load variations which can cause chirp. The capacitor is attached to the next stage, Q2, a class-A amplifier. This amplifier raises the level of the signal to the level needed to drive the Fun-Mitter.

Q2 is direct-coupled to the final stage, Q3, an emitter follower. This stage provides excellent isolation between the oscillator and the transmitter as well as providing an impedance match between the two. Without Q3, as in the original design,

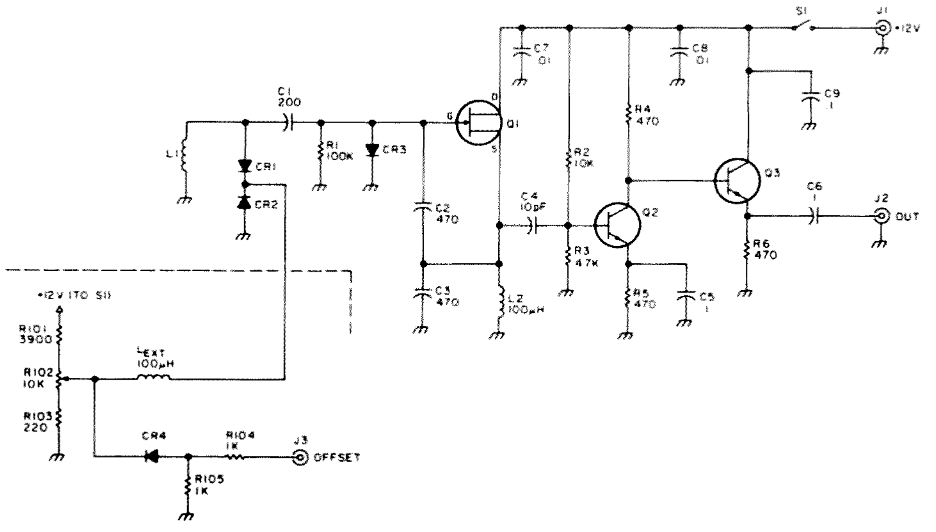


Fig. 1. Schematic of vfo.

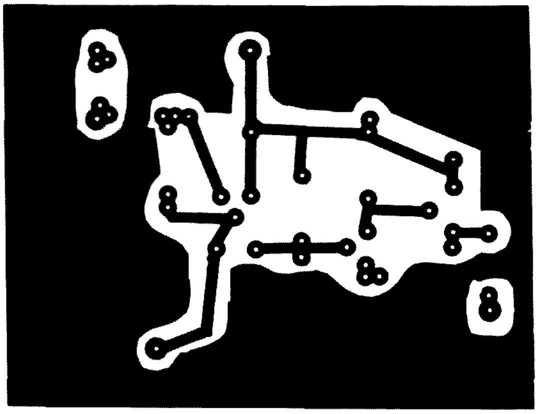
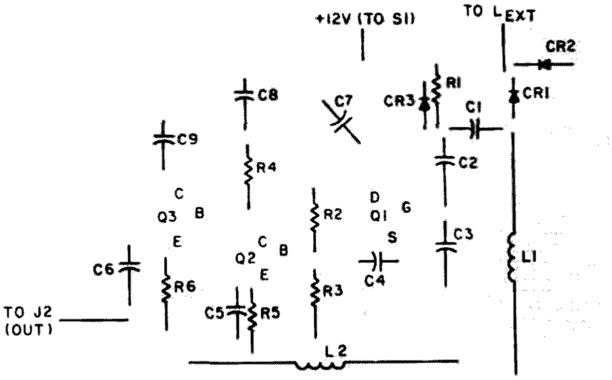


PC layout for vfo.



Component location.

PC boards for the vfo are available from the author for $7 ppd. PC boards for the previous articles also are available as follows: Fun-Mitter—$7 ppd; Fun-Ceiver—$7 ppd; Filter—$3.50 ppd.

Parts List

Designator	Value	Radio Shack Part Number
C1	200 pF NPO (approx.)	272-801
C2, C3	470 pF NPO	272-801
C4	10 pF (use two 4.7 in parallel)	2-272-120
C5, C6, C9	0.1 μF	272-135
C7, C8	0.01 μF	272-131

the vfo is not stable when the transmitter is keyed.

CR4 is used to shift the frequency of the vfo when the transmitter is not in use and you are listening to the receiver. It does this by changing the voltage at the junction of CR1 and CR2, which shifts the oscillator frequency. Without this feature, the vfo signal would appear on the listening frequency and make listening impossible!

Construction

The construction of the vfo is intended to be goofproof. It is built on a 2¼″ × 3″ single-sided board just as the transmitter and receiver were. It cannot be overemphasized that the circuit should be built on a PC board. Nearly all of the problems that readers had in building the previous two pieces of gear were due to breadboard or point-to-point construction. If you are an inexperienced homebrewer, it is fairly easy to make mistakes when wiring the circuit apart from a printed circuit board.

I built my vfo in an enclosure that matches the enclosures used for both the transmitter and receiver. Also, the front-panel layout was made compatible to enhance the appearance of the gear.

As can be seen in the photographs, the tuning potentiometer (R7) is mounted on the front panel. The associated resistors and inductor (R6, R8, L3) are also mounted on this potentiometer, and wires run from there to the appropriate circuit points.

The rear panel contains three jacks. One is for the vfo output signal, and one is for the vfo offset. The connection between the vfo and transmitter should be made with coaxial cable (RG-174 or RG-58).

Operation

The vfo is best operated with a battery rather than an ac supply. This eliminates any possibility of ac hum on the transmitted signal. It also helps improve frequency stability. Two 6-volt lantern batteries in series will power the vfo for a long period of time. If the Fun-Mitter is powered by batteries, the needed 12 volts can be tapped from those batteries.

Tuning and operation are very easy: Only one adjustment needs to be made—setting the vfo on frequency. This is accomplished in the same manner as was done in the receiver. Using a separate receiver, listen on the frequency you want the low end of the vfo to be set on (for example, 7100 kHz). Drape a length of wire near the vfo and attach the other end to the receiver

antenna input. With the vfo on and warmed up, slowly spread or compress the last few turns of L1 until the vfo signal is heard in the receiver. This adjustment should be done with the tuning potentiometer (R7) fully counterclockwise. Finally, verify that the vfo covers approximately 70 kHz if built for 40 meters and 50 kHz if built for 80. That's all there is to the adjustment.

To operate the vfo, two connections need to be made—one to the transmitter crystal socket and one from the vfo offset input to J3 of the Fun-Mitter. (This jack was added to provide receiver mute operation for the Fun-Ceiver.)

If C_{opt} was not included in the Fun-Mitter, then the vfo signal can be applied directly to the crystal socket terminals (see Fig. 2). If C_{opt} was included, remove its connection and connect that terminal of the crystal socket to ground. An inspection of the Fun-Mitter schematic will reveal that even this step is not necessary if a method can be derived to connect the shield of the vfo cable to ground of the Fun-Mitter. Alternatives such as a rear-panel phono connector on the Fun-Mitter also can be used. A plug can be made easily from two ½" to ¾" lengths of #12 gauge copper wire. Solder the vfo signal and ground leads to these wires and plug them into the appropriate crystal socket pins.

Once the vfo is plugged in and turned on, verify that the transmitter operates as it did before. With the vfo in use and all connections in place, the vfo signal should be heard only when the transmitter is in the transmit mode (due to the vfo offset feature). Zero-beat the vfo with the transmitter in the transmit position and the key down. Remember that when using a direct-conversion receiver, you must zero-beat the correct side of the signal you are listening to.

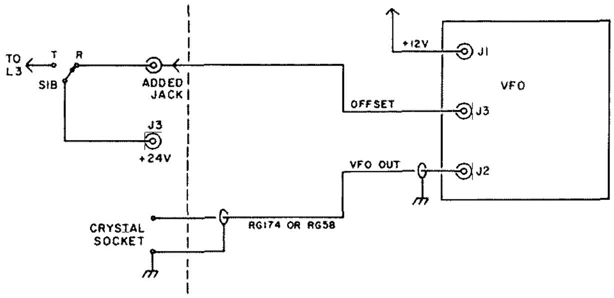

Fig. 2. Connections between vfo and Fun-Mitter.

Crystal operation still can be used by simply removing the vfo leads and plugging the crystal back in.

It should be possible to use the vfo with low-power solid-state transmitters other than the Fun-Mitter. However, modifications may be necessary to the transmitter if the oscillator is not configured as in the Fun-Mitter.

Conclusion

The vfo should be simple to build and goof-proof in its operation. Many more contacts now should be possible due to the ability to move to the frequency the other station is on. This series will be continuing in the months to come with additional goof-proof projects. Meanwhile, enjoy the Variable Fun Oscillator! ■

Here is a weekend project that combines two instruments and an old technique into a very handy gadget to have around the shack. First, it's an 8-to-10 Watt 52-Ohm dummy load with a calibrated wattmeter: perfect for tuning up low-power transmitters. Second, it's also a calibrated rf resistance bridge which can make antenna adjustments a lot easier by telling you more about the nature of a mismatch than a plain swr bridge will. The old technique provides a nice tie-in between these two instruments and gives some benefits besides: The dummy load is also a resistive power divider that provides a low-level driving signal for the rf bridge.

One benefit of this arrangement is that the power source sees a load which is essentially independent of the bridge load. That means you can load your QRP transmitter into this instrument, put that new antenna on the bridge output, and fool around to your heart's content without risk of damaging the transmitter or even detuning its output stage. In addition, the power delivered to a 50-Ohm load is only about 40 mW when the power coming out of the transmitter is 5 Watts. That is a 21 dB reduction, and it means that any signal you radiate while adjusting the antenna is 3-1/2 S-units less than it might have been—certainly a neighborly gesture on today's crowded bands.

Background Theory and Circuit Description

There is nothing new or unique about the circuits described here. Rf resistance bridges have been around longer than the more familiar high-power swr bridges and there are several examples in recent publications.[1,2] The dummy load/power divider technique was described in *Solid State Design for the*

Radio Amateur (ARRL) and recently used in a transmatch tuning circuit described in *QST*.[3]

What I hope to emphasize here is this instrument's usefulness as a matching aid, the simple and inexpensive nature of the circuit, and the fact that the same circuit can be used as a dummy load with a built-in calibrated wattmeter. It's like getting two instruments for the price of one, and the final result is a very handy piece of test gear.

The resistive rf bridge is a simple modification of the classic low-power swr bridge, so before getting down to circuit details let's consider swr bridges in general for a moment. There are two main types of bridges used for measuring swr, and the most common type is a high-power handling circuit meant to be left in the transmission line for continuous monitoring. Usually, this type of bridge requires a minimum of 5 Watts or so driving the load before the meter readings are large enough to interpret accurately. This occurs because the bridge itself is very loosely coupled to the transmission line, typically through a few picofarads or several inches of wire running parallel to the center conductor of the main line.

The other type of bridge is inherently a low-power instrument. The driving signal runs right through the resistive elements which make up the bridge, so the bridge itself must be able to absorb a large fraction of the input power. The resistive bridge doesn't find much use in amateur circles because it requires only a Watt or less of drive and can't be left permanently in the line; it's strictly an occasional-use test instrument.

There is nothing wrong with continuous swr monitoring. After all, the familiar deflections of the high-power monitor do give a constant verification that the transmitter is tuned and the antenna connected. The low-power test instrument described here has some advantages over the usual swr bridge, though, especially for initial antenna adjustments, because it tells you more than just the magnitude of a mismatch.

Swr can be defined several ways, and one is the ratio of a load impedance to the transmission line's characteristic impedance (which is almost always near 50 Ohms in current amateur usage). For example, to cause a 3:1 swr, a 50-Ohm cable could be terminated with either 150 or 16.6 Ohms. These are purely resistive loads, but there is also an infinite number of reactive loads which would give the same 3:1 swr, and a common swr bridge can't tell the difference between any of them. You can build a bridge to measure both the reactance and resistance present in a load,[4,5,6] but such bridges tend to be too complex for my taste and requirements.

When matching a load to a 50-Ohm line, I generally have two questions. Is it resonant, and what's its resistance? If a load is resonant (and that's how I want all my antennas to be), then it has no reactive component—just resistance. If I know the value of that resistance, then I know the swr and whether I need more or less resistance to get a match. I'll give an example at the end of the article, but right now let's look at the schematic shown in Fig. 1.

There really isn't much to the circuit diagram. The input signal is terminated in a 53-Ohm dummy load constructed with a series-parallel resistor assortment. The voltage development across the 10-Ohm portion of that dummy load drives a simple bridge circuit made up from a 250-Ohm pot, a 51-Ohm standard resistor, and the load impedance. The bridge error signal appears between the output connector and the potentiometer arm and is detected by a germanium diode. The result is then indicated by a 100-uA meter in a voltmeter circuit.

Bridge operation is equally straightforward. When input power is applied to the instrument, it develops a voltage across the 53-Ohm dummy load. About 1/5 of this voltage appears across the 10-Ohm portion of the dummy, and this is the driving voltage for the resistance bridge. Some fraction of this driving voltage shows up between the potentiometer arm and ground, the exact amount depending, of course, on the shaft position. Similarly, there is some other fraction of the bridge driving voltage appearing across the load terminal, this fraction depending on the load resistance connected there.

If there is no load connected, then the entire source voltage appears there and we'll make use of that fact later to calibrate the wattmeter portion of this instrument. If a 51-Ohm load is connected, then exactly half the source voltage will be there. The difference between the output voltage and the potentiometer arm voltage is rectified by the diode and drives the meter through the sensitivity control, so with the 51-Ohm load the bridge will show a null when the pot travel is exactly centered. Other load resistances will show nulls at other positions and the potentiometer dial may be calibrated by marking the nulls corresponding to a whole series of load resistances. In theory, the bridge should show nulls for every load resistance between zero and infinity, but in practice this doesn't happen because the potentiometer isn't infinitely adjustable.

The circuit can be calibrated pretty accurately for resistances between 5 Ohms and 1k, with the best resolution around the center of the dial at 20 to 150 Ohms. Notice that the bridge cannot be nulled completely if the load has a capacitive or inductive component since such a load would introduce a phase shift between the bridge source voltage and the bridge load voltage. As there is no corresponding phase shift between the bridge source voltage and the potentiometer arm voltage, there never will be a point where the diode voltage will be zero and the meter nulled. Even when the voltages at each end of the diode are equal in amplitude, the fact that they are phase-shifted with respect to each other guarantees that there will be a sine wave or error voltage for the diode to rectify. In practice this means that unless the load is a pure resistance there will not be a true null but only a partial dip in the meter reading as the potentiometer shaft is turned.

A true rf impedance bridge would have two null adjustments: one for rf resistance and one for reactance. With such a bridge you can completely define any mismatch, but, as noted earlier, that's often unnecessary, especially in antenna work where the goal is to tune out reactance by resonating the antenna. You can always tell when a load is resonant with the resistance bridge because at resonance the null will be complete. Then steps can be taken if necessary to transform the remaining impedance to match a 50-Ohm line.

Reader Service for facing page ↙81→

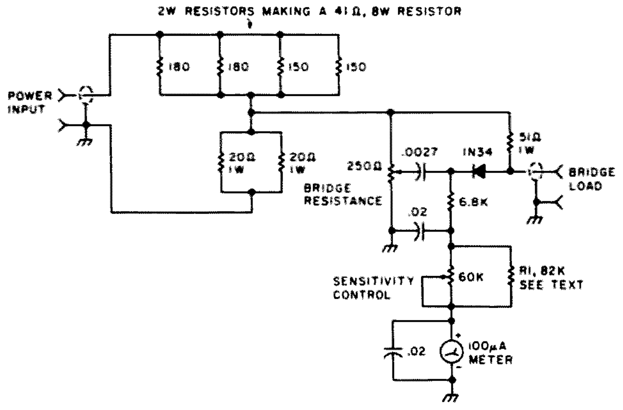

Fig. 1. Schematic diagram of dummy load/wattmeter/rf bridge. R1 is chosen as necessary to calibrate the wattmeter.

This same bridge circuit can be used to measure the power delivered to the dummy load by the transmitter. A glance at the schematic will assure you that with no load connected to the bridge and the resistance dial set to zero Ohms, the voltmeter circuit will indicate the rf voltage across the 10-Ohm portion of the dummy load. Knowing that voltage, we can easily calculate the voltage across the whole dummy resistance, and knowing that, we can calculate the power there from $P=V^2/R$. The calibration can be accomplished using only a dc voltmeter and will be described shortly.

Construction

A lot of articles begin their construction description with the assurance that "the layout is completely noncritical." That is certainly not true here, but "critical" is also too strong of a word, so let me just caution you to be careful with layout. There are three main areas that can cause trouble.

First, it's best to arrange the dummy load portion of the circuit so that current flowing in the ground path from the bottom of the dummy load back to the input terminal does not share any conductor with part of the bridge circuit. If it does, then variations in the input power will shift the null positions on the resistance dial. Photo B shows one way to solve that problem by bringing the input power and its ground return to the dummy resistors on a single piece of coax, thus avoiding the temptation to ground the bottom resistors to some point on the chassis.

Second, the detector diode should have one end connected directly to the output jack. My first few attempts had more compact physical arrangements with the diode connected to the bridge output terminal with lengths of wire or brass strips. This always interfered with getting good deep nulls on both ends of the resistance range.

Third, the detector should not be a silicon diode, since the 0.6-volt threshold of a silicon diode will cause the bridge nulls to be too wide. With a given load termination there should be a single, sharp deep null on the dial, not a dead zone covering several degrees of rotation. My collection of diodes is pretty large, and the best of the lot turned out to be some germanium 1N34 equivalents I paid 10¢ each for some 15 years ago! Radio Shack's 276-1123 diodes cost the same today and should work as well.

The dummy load nominal value is about 51 Ohms with the circuit shown. I used an assortment of resistors from the junk box, so feel free to substitute values, but do observe a few simple rules. Wire-wound resistors are definitely out because they look like coils at radio frequencies. Also, stick with carbon resistors having values less than 1k. When paralleling resistors, try to have them all of the same value so they dissipate equal amounts of power. Keep the leads short and the wiring direct; this keeps the dummy load looking resistive at the higher frequencies and prevents stray coupling which might interfere with the bridge nulls.

The rest of the physical arrangement is pretty clear from the photographs with the exception of the bridge potentiometer mounting. A similar bridge is described in W6SAI's 1962 *Radio Handbook*[7] and the author there cautions that stray capacitive coupling between the potentiometer resistive element and ground can cause frequency sensitive errors in calibration.

The suggestion made there, and followed here, is to cut a large hole in the box (say, 1-1/2" in diameter) and mount the pot in the center of this open space using a piece of insulating plastic, bakelite sheet, or unplated circuit board for support. This insulates the pot body from ground and thereby greatly reduces the capacitive coupling between the pot resistive element and ground. It seemed like a good suggestion so I followed it. I can't strictly say it is necessary because I didn't try it the other way, but it sure can't hurt.

The skirt on the resistance dial covers the hole from the front of the box. If you want to use a smaller knob with a pointer, you could mount a rectangle of insulation over the hole from the front side of the panel and use that to hold the pot and the calibration marks. The actual value of the bridge potentiometer is not too critical. It should be at least 50-Ohms so that it doesn't draw too much power, and anything over 1k is probably asking for trouble with stray capacitance. If you have anything inside that range, try it before you buy a new 250-Ohm unit.

The box shown is a cut-down Bud minibox that started out as 3" × 4" × 5". The 3" height was reduced to just under 2" because it fit the hand better, but there is nothing magic about these dimensions. Use anything of roughly the same size as long as it is made of metal. You also will note in the photographs that BNC connectors are used instead of the more common (in amateur circles, anyway) UHF series. I don't run enough power to require RG-8, and I find the smaller quick-connect BNC connectors more convenient for my home-brew projects. Naturally, if all of your antenna cables have UHF connectors, then you also should use them on your bridge.

Calibration

There are two things to calibrate here: the wattmeter and the bridge scale. The meter serves as a null indicator when using the bridge, so the wattmeter calibration can be done after the bridge has been checked out.

The bridge dial can be as simple or fancy as desired but it should be large enough to read easily. The skirt on my dial is 2-1/4" in diameter. You probably will want to start with a paper scale and save the fancy artwork until everything is working properly.

Assemble a collection of carbon resistors covering as

many values as possible between 5 and 1000 Ohms and then cut the leads to about 1" in length. The leads are bent so the resistors can be spring loaded into contact with the bridge output connector. If you have a lot of spare connectors, you also could make up a number of dummy loads with the different resistors similar to the one shown next to the bridge in Photo B.

Any layout problems will be more pronounced at the higher frequencies, so fire up a 10-meter rig if you have one and feed several Watts of rf into the bridge. (I've used this instrument only on 10 meters, but it might work all right up to 6 meters.) With the bridge excited, check the nulls at both ends of the range, say, with a 10-Ohm then a 680-Ohm load.

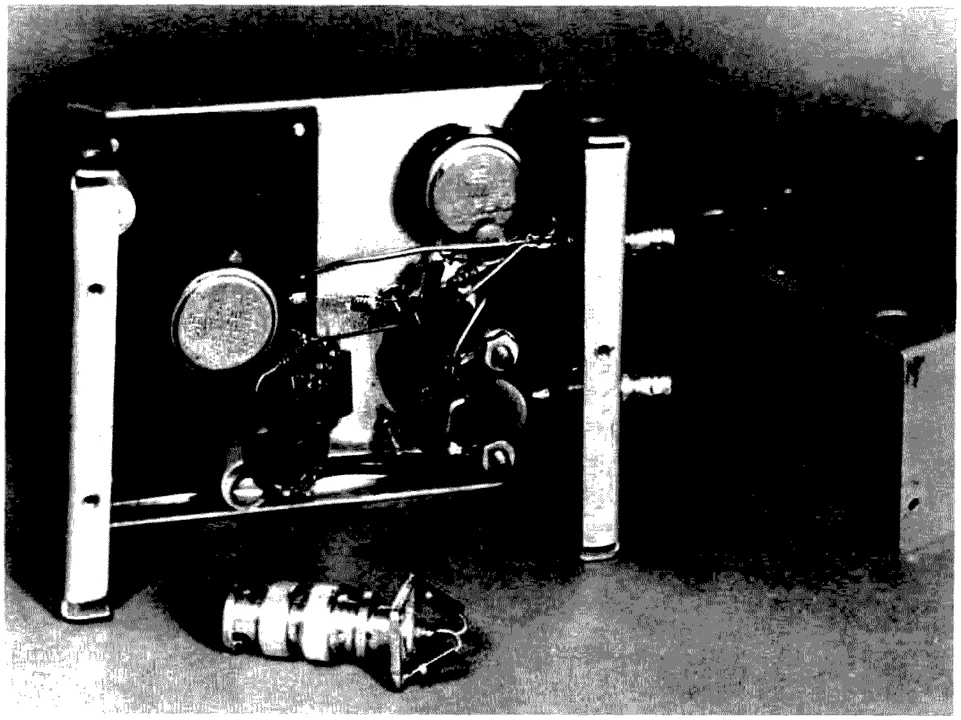

Photo B. Interior of the instrument, showing layout and construction details. The object in the foreground is a dummy load typical of those used during calibration.

Both nulls should be deep and well defined. If one isn't as deep as the other, then there is probably something wrong with the physical layout of the bridge elements. Try moving things around some or try another ground routing. If you followed the layout shown, then there really shouldn't be any trouble. Remember that this is an rf resistance bridge and with resistors on the bridge output, the nulls theoretically should be right down to zero meter movement. In practice, stray reactances prevent the nulls from being perfect but they should come pretty close to it. If the load does contain some reactance, there still will be a dip but it won't be to zero as previously mentioned.

When you're satisfied with the basic bridge operation, make a temporary scale and mark off the positions of the nulls due to the collection of sample resistors. Standard resistor values aren't nice round numbers, but with enough calibration marks you can make a final scale with lines at 5, 10, 20, 30, etc., Ohms as shown on the front panel in Photo A.

The wattmeter scale can be calibrated easily using a dc power supply and a good dc voltmeter. Remember that the wattmeter is actually reading the rf voltage across the 10-Ohm portion of the dummy load when there is no bridge load and the bridge pot is set to zero Ohms. Under these conditions, the 0.0027-uF coupling capacitor (that's not a critical value—anything from 0.001 to 0.05 will work as well) will charge to the peak value of the rf sine wave.

Since the peak value of a sine wave is 1.414 times the rms value, it is easy to calculate a dc value which, when fed into the instrument, will read the same on the meter as some given rf power. A conversion chart for the 53-Ohm dummy load is given in Table 1 along with the equation necessary to calculate your own equivalents should you use some other combination of resistors. Since I was interested in converting CB sets, I calibrated my wattmeter for a full-scale reading of 5 Watts, even though the resistors can handle 10 Watts for short periods. To make the 5-Watt calibration, feed a measured 22.9 volts into the unit, turn the sensitivity control all the way down (maximum resistance), and select a value for R1 that gives a full-scale meter reading.

Now comes the hardest part: making the meter face. I don't like conversion charts so I made a whole new face for my meter. It's not as difficult as you might think, but it does require a steady pair of hands.

Open the meter, remove the two screws holding the faceplate in place, and remove the faceplate while taking care not to damage the meter pointer. Glue a clean piece of white paper over the old faceplate using paper paste and not liquid white glue (which tends to dampen the paper so much that it wrinkles). Be sure to cover the faceplate evenly with paste so the paper won't have a chance to wrinkle. The pointer travels close enough to the faceplate that it can get stuck on wrinkles.

When the paste is dry, use a sharp knife to trim off the excess paper, and a pin to punch through the screw holes. Now a drawing set with an ink compass can be used to draw in a nice arc for the baseline of the new scale. Remount the faceplate, center the meter zero adjustment, and make a light pencil mark under the pointer tip to define the zero rest position. Reapply the 22.9 volts and make another pencil mark to spot the 5-Watt full-scale position. Now go down the list in Table 1 and mark off each intermediate point, checking occasionally that all of the points are repeatable and properly marked.

Finally, remove the faceplate again and finish off the scale graduations with

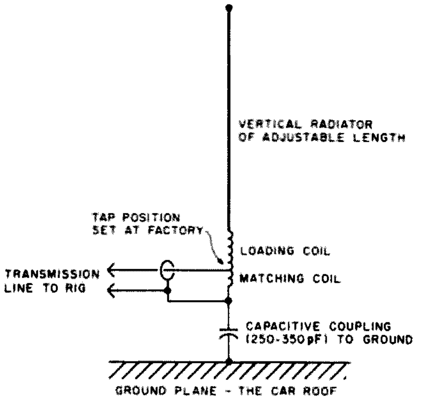

Fig. 2. Shortened loaded vertical, a CB mag-mount whip.

ink or dry transfers using the light pencil marks as a guide. With a little care, the results can be pretty professional. One real bonus of this technique is that the calibration is correct with the particular diode, resistors, and meter actually used, since the whole circuit is calibrated at once. That's important because the diode is not a perfect rectifier and the meter scale will be influenced slightly by the characteristics of the particular diode used.

An Application Example

The most obvious use for the rf resistance bridge is in making matching adjustments to antennas. Some antennas, dipoles, for example, are easy to adjust with an swr bridge since their feedpoint impedance at resonance is already close to the typical cable impedance. When a dipole is fed with either 52- or 73-Ohm coax, its swr at resonance is bound to drop to somthing like 1.5:1. This isn't true with shortened antennas such as mobile whips since their feed impedance may be only a few Ohms.

Input Power Watts	Dc Voltage Equivalent
5.0	22.90
4.0	20.49
3.0	17.74
2.0	14.49
1.0	10.24
0.5	7.24
0.4	6.48
0.3	5.61
0.2	4.58
0.1	3.24

Table 1. Wattmeter calibration. Input power levels corresponding to dc voltage equivalents. Values are calculated using $E = \sqrt{2RP}$, where P = rf power (in Watts), R = total dummy resistance, and E = dc input voltage (where E is peak value of rf sinewave). Caution: With these dc inputs, the dummy load is dissipating twice the indicated rf power, so be careful not to overheat the resistors.

There are two adjustments necessary to get a low swr with such an antenna: one for resonance and one for impedance matching. Making these two adjustments with only an swr bridge can be very difficult because a low swr will result only when both settings are correct. With a resistance bridge, the adjustment is much easier.

Consider the antenna shown in Fig. 2, a magnetically-mounted, base-loaded CB whip. The antenna really has two adjustment points, although the tapped loading coil is normally adjusted and sealed at the factory and all that is necessary for 27-MHz operation is a slight height adjustment. Putting this antenna to use on 10 meters or using a different length whip section may change things enough that a low swr cannot be achieved without a change to the coil size or tap position.

For example, I am using one of these antennas on the roof of my house as a loaded ground plane. The eight 1/4λ radials laid out on the roof do not provide the same type of ground return as the roof of an automobile. In addition, a 5' whip is being used as a radiating element in place of the original 3' length. This longer length lets me use a smaller loading coil with lower losses. I built this test instrument partly because of the difficulty I was having trying to tune this antenna with only an swr meter and grid dipper.

Adjusting such an antenna is a lot simpler with the rf resistance bridge, but first the bridge must somehow be connected to the base of the antenna. It would be nice to locate the bridge physically at the base of the antenna but this isn't always practical. For one thing, the bulk of the operator's body would probably upset the antenna tuning. If the bridge is connected to the antenna through a length of coaxial cable then that cable length must be chosen carefully because the impedance seen looking into a transmission line depends on three things: the line impedance, the load impedance, and the line length.

Luckily, it happens that a section of transmission line which is some multiple of a half wavelength in length will have an input impedance almost exactly equal to its load impedance. Using such a line makes it possible for the bridge to be located at some convenient position and still indicate the antenna base impedance. At 28.5 MHz, a half wavelength in free space is 16' 5" and in coaxial cable it will be about 2/3 of that or 10' 11".

If you have a section of cable this length, it is easy to check its electrical length with the bridge. First put a 10-Ohm resistor directly on the bridge and check for the null at 10 Ohms. Then insert the cable section between the bridge and resistor and see that the bridge still reads a resistive 10 Ohms. If it is a little off, as indicated by an incomplete null somewhere near 10 Ohms on the dial, you may want to change the transmitter frequency a bit to adjust the operating wavelength to the line's physical length.

Just for fun, you might try a quarter wavelength of cable and verify that it transforms the 10 Ohms into 270 (52-Ohm cable). In fact, you might get out a good article on transmission-line matching sections and try a number of things with different loads and line lengths—it's fun and really brings that dry old theory to life.

With the antenna fed through some multiple of a half wavelength of cable, the radiator length can be adjusted for resonance as indicated by a complete null of the meter reading. The resistance indicated at resonance is the feedpoint impedance of the antenna, and the ratio of that impedance to 52 Ohms is the swr on the cable—assuming you're using 52-Ohm cable. If the swr is more than 2:1 (antenna impedance greater than 100 or less than 25 Ohms), then you may want to change the coil tap position. It probably is easier to change the inductance below the tap by squeezing or separating the coil turns there slightly than it is to unsolder and move the tap itself. These adjustments can be pretty fine and you probably won't end up changing the coil size by a whole turn's worth anyway.

With the inductance changed, look for the new null on the bridge and, once again, adjust the antenna

height until the feedpoint impedance is pure resistance. Depending on whether that resistance is closer or further from the 52-Ohm target, you now know in what direction the coil must be altered to effect an acceptable match.

Conclusion

Of course, there are many other tuning applications for this instrument besides CB antenna conversions. You will find it more useful than an swr bridge for any application which requires both resonating a load and transforming its impedance. As a bonus, you can use it to measure swr when the load impedance is mostly resistive. The internal dummy load lets you adjust and modify antennas without danger to your transmitter and without putting a big signal on the air. You'll also find that the dummy load and calibrated wattmeter are a valuable QRP tune-up aid. Last, but not least, you can develop a real understanding of transmission-line matching techniques by using the bridge to verify some of the theory you read when studying for your ticket! ■

MBA READER™, A NAME YOU SHOULD KNOW

What does MBA mean? It stands for Morse-Baudot and ASCII. **What does the MBA Reader do?** The RO model (reader only) uses a 32 character alphanumeric vacuum fluorescent display and takes cw or tty audio from a receiver or tape recorder and visually presents it on the display.

The copy moves from right to left across the screen, much like the Times Square reader board. **Is the AEA model MBA Reader different from other readers?** It certainly is! It is the first to give the user 32 characters of copy (without a CRT), up to five words at one time. It can copy cw up to 99 wpm and Baudot at 60-67-75 and 100 wpm. Speeds in the ASCII mode are 110 and hand typed 300 baud. The expanded display allows easy copy even during high speed reception.

The AEA model MBA has an exclusive automatic speed tracking feature. If you are copying a signal at 3-5 wpm and tune to a new signal at 90 wpm, the MBA catches the increased speed without loss of copy.

The MBA Reader allows a visual display of your fist and improves your code proficiency. It is compact in size, and has an easily read vacuum fluorescent display.

The Reader operates from an external 12 VDC source. This allows for portable/mobile or fixed operation.

Check the AEA model MBA Reader at your favorite dealer and see all the features in this new equipment. If your dealer cannot supply you, contact

Police Freqs for the TR-2400

—a sleepless night for the mod squad

I do not need to extol the bounty of convenience and luxury Kenwood's new TR-2400 hand-held 2-meter transceiver has brought to VHF enthusiasts. Most hams, no doubt, have seen or read of its features—notably 10 channels of programmable memory and its ability to scan these memories, stopping on active or inactive channels. Being strictly a VHF enthusiast, my mind began to drift when my TR-2400 arrived to what the next advance in radio/scanner technology would bring forth. It didn't take very long to imagine the first tri-band programmable hand-held scanner.

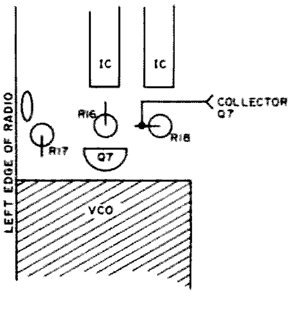

Fig. 1. Vco location.

After all, the TR-2400 had broken the ground, at least in a single-band version.

I also began to ponder the possibilities of converting the TR-2400 to the "action band." One sleepless night was spent tracing the schematic lines and deciphering its method of operation. I would like to thank Trio-Kenwood Corporation for their practice of supplying block diagrams and full schematics with their products. I wish all manufacturers would make it a policy to do the same with every unit. This ham, for one, distrusts "black boxes."

Several possibilities emerged to modify the TR-2400 so that reception in the 154- to 158-MHz range would be possible. Three of them will be outlined here, from simple to complex. The simplest of these is currently working in my rig. The second requires moderate circuit modification, but may not work depending on the range of the vco. The third method requires additional parts and good instruments to adjust, but is sound in theory. I present these here in hope that someone else will follow my theories, try to implement them, and report their results. I cannot because I begin Navy pilot training at Pensacola, Florida, within two weeks of writing this draft and don't have the time!

Theory in Operation

The operation of the TR-2400 is fairly straightforward as frequency synthesizers go. Referring to your owner's manual (pages 14 and 15) with the following description may be helpful, but not necessary, to follow the principle of the synthesizer.

Transistors Q7 and Q8 and associated power supply pass transistors Q2 and Q3, respectively, form a complementary electronic switch—i.e., when Q2 is ON during receive, Q3 is OFF, and vice versa during transmit. Q2 controls the fixed frequency receive beat oscillator/tripler (X1, Q1). Q3 controls the transmit beat oscillator/tripler (X2, Q4). During transmit, positive bias on the base of Q7 causes it to conduct to ground and turn off Q2 and Q8, which turns on Q3 and Q4.

The output of Q4 (138.5 MHz) and the VHF voltage controlled oscillator (vco, Q10) are mixed, filtered, and amplified by Q5 and Q6. This forms a downconverter, much like the i-f system when in a receiver. As shown on the block diagram in the manual, the output of Q6 is always between 5.5 and 9.5 MHz for 2-meter operation (144.0−138.5 = 5.5 MHz). The full range is 5.4 MHz to 9.995 MHz. In receive mode, pass transistor Q2 activates Q1 (127.8 MHz) and D3. The output of Q1 is lower than Q4 by 10.7 MHz, which is the i-f frequency. In order to keep the output of Q6 between 5.5 and 9.5 MHz, the vco must drop its frequency by 10.7 MHz, too. Most of this drop is accomplished by D3 bypassing C27 when forward bi-

ased, effectively *increasing* the value of C26 (the value of two capacitors in series is lower than the smallest value; bypassing one of them therefore increases the value of capacitance in the circuit). This lowers the vco frequency by about 10.7 MHz.

IC Q20 is a binary-encoded 3½-stage decade programmable counter (i.e., it divides by any integer, not just powers of two). Actually, as used here, only 3 decades are programmable: units (A1-D1), tens (A2-D2), and hundreds (A3-D3). The thousands half stage (A4-B4) is wired at one thousand (i.e., A4 goes to Vdd and B4 goes to ground, a binary one). Frequency division of the signal from Q6 is therefore 1000 plus whatever is loaded into Q20 by the microprocessor, Q25 (and interface ICs Q23 and Q24). Divisors range from 1080 at 143.900 MHz to 1999 at 148.495 MHz, the limits of the TR-2400.

The phase comparator reference frequency (5 kHz) is derived from X3 (10.240 MHz) and fixed binary divider IC Q22. To get 5 kHz in this case, a divisor of 2048 is used, which is 2^{11}, hence pin Q11 on the schematic. 10,240 kHz ÷ 2048 = 5 kHz.

The divided outputs from both IC Q22 (reference) and IC Q20 (signal) are fed to IC Q21, the phase comparator. Any difference between phases in the two signals (usually caused by a difference in frequency) causes an error voltage to appear at pin 1, "AMP OUT." This output is proportional in magnitude to the phase difference of the two signals. This error voltage is applied to D2 (actually a varactor diode) to tune the vco frequency and hence correct the phase difference the comparator in IC Q21 senses. Simultaneously, this voltage is fed to four varactors in the front end (D1-4) to ensure peak tuning across the band in the receiver front end. The error voltage was measured at nearly 1/2 volt per megahertz of frequency change.

Back to the beginning for a moment. The transmit/receive switching voltage used to drive Q7 and Q8 is closely associated with the biasing voltage for diodes D9 and D8/D27. These diodes select the routing of the vco output signal to either the receiver (D9) or the transmitter (D8/D27) as it is needed.

To complete the theory of operation, the deviation for transmitting is developed in the vco. Output from microphone amplifier IC Q13 is applied to D5 in the vco, another varactor. Thus, modulation is true FM, produced directly at the VHF frequency without the use of frequency multipliers.

Conversion

The most commonly used portion of the VHF-hi public service band of usual interest lies almost exactly 10 MHz above the 2-meter amateur band (154 to 158 MHz). The transmitter frequency from the vco (143.9 to 148.495 MHz) is an appropriate injection frequency to the receiver for nearly the same range (+10.7 MHz = 154.6 MHz to 159.195 MHz).

The only trick necessary to accomplish this higher injection frequency is to use the higher-frequency transmitter beat oscillator (Q4) with the receiver and turn off the receiver beat oscillator (Q1) and D3. Two wires can be rerouted through the S. TONE switch (if not being used) to shift the receiver up band. No critical or sensitive circuits are disturbed, so performance is virtually ensured.

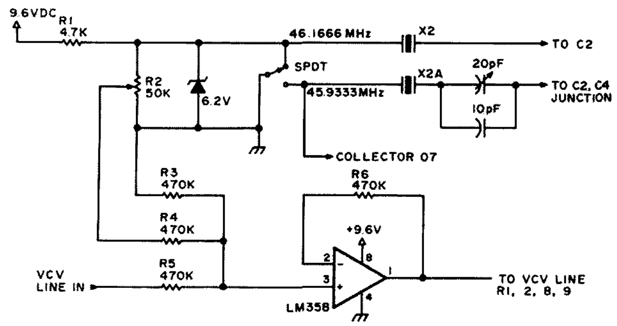

Fig. 2. Suggested circuit. Note: LM358 is a dual op amp in an 8-pin DIP designed for single-ended power supplies.

In operation, the collector of Q7 is bypassed to ground, which switches the oscillators, as needed, but not the radio circuits.

The Mod

Turn the radio off and the TX offset to BU OFF. Remove the four rear screws, back cover, battery cover, battery pack, and the two screws beneath the battery holder. Disconnect the battery. Locate the empty area in the center of the rear circuit board where the tone board would go. Find the red (V+) and black (ground) wires and short them together (use a piece of insulated wire if you like). The red line will be disconnected from V+ in a moment. Replace the back cover without screws.

Turn the radio over, face up. Carefully lift the face plate up and off to the right. All these ICs are CMOS and could possibly be destroyed by static charges on loose fingers or tools. There is no need to touch these, so *don't!* Note: You will be on a remote lead of the microprocessor (PA2), but this lead has static protection (C9, R66).

Find the S. TONE switch assembly in the top, center. Just to the right of this switch is a black wire marked B1. Follow this wire down to the bottom edge of the board. Remove this one end of the wire from this point by cutting or unsoldering it. This disconnects the red wire on the bottom board from V+. Lay the black wire aside.

In the lower left corner is a shielded portion of the circuit. This is the vco. At the top of this box is transistor Q7 and its associated resistors. To the right, in the 2 o'clock position, is R18. See Fig. 1. The wire lead of R18 is the connection point for the end of the black wire removed above. The lead on R18 has a ceramic coating for insulation, part of which must be removed to make a place to solder the black wire. This coating will chip away easily under a pen knife, razor blade, or even serrated plier tips if done very gently. After removing the insulation, solder the black wire to the resistor lead quickly. These small resistors won't handle much heat for long. Don't break the circuit. This is just a convenient attachment point.

That is the entire modification. Put the case together, careful not to pinch any wires, and connect the battery pack. Be careful not to overtighten the screws. Turn the radio on before moving the TX OFFSET switch from BU OFF.

Operation

This modification causes the ON AIR indicator to be on when the S. TONE switch is depressed. The transmitter is *not* on. The microprocessor (pin PA2) reads the collector of Q7, which you just shorted to ground, as the transmitter.

MON-FRI 9:00—5:00
SAT 9:00—12:00 ✓139

Write: 1465 Wells Stat. Rd., Memphis, Tn. 38108

Only the transmit beat oscillator is on. While in this mode, I suggest you keep the F LOCK *ON* and the TX switch in the STOP position to avoid inadvertent transmission while monitoring. If you do transmit, the transmission will be in the amateur band as usual.The transmitter is *not* shifted up band by this modification.

To receive the desired new channel, subtract 10.7 MHz from the known frequency (e.g., 155.61 MHz − 10.7 = 144.91). Make sure the S. TONE is off (up position) and program the radio as usual for the corrected frequency (e.g., 4.910). Now depress the S. TONE switch. As the ON AIR flag appears, your radio is tuned to the new channel.

While in this mode, the keyboard will not function, just as if you were transmitting; thus, there is no band scan or memory scanning. These features may be regained by the more complex modifications, or by isolating pin PA2 of the microprocessor and keeping it near Vcc (which I do not recommend). If the radio is turned on with the S. TONE switch already depressed, an incorrect display is likely to occur. Simply turn the S. TONE switch *off*, then *on* again to correct the readout. Receiver sensitivity in the new band will fall off because varactors D1-D4 (front end) are not being properly tuned for this higher range. However, sensitivity remained sufficient to receive my local sheriff's department near the edge of the county.

Other Theories

The best theory requires some careful circuit work, but has great promise. Basically, if you add 2000 to the divisor at IC Q20, all frequencies would be shifted up by exactly 10.0 MHz. This is easily done by lifting B4 from ground and connecting it to Vdd, or A4. Thus, programming would be just as on 2 meters—just the last 4 digits of the frequency, without the need for a correction factor. Using this higher divisor would allow using the receive beat oscillator and keep band and memory scan capability.

The easiest way to keep the vco working 10 MHz higher than usual above the receive beat oscillator is to isolate D3 in the vco by breaking the control line from Q2. An additional switch would be needed to switch it back in for normal two-meter operation.

A more extensive circuit addition may yield better results. The AMP OUT line from IC Q21 goes from about 1.2 volts to 3.4 volts (a range of 2.2 volts) from 143.9 MHz to 148.5 MHz (a spread of 4.6 MHz), or roughly +.5 volts/MHz. Thus, to go 10 MHz higher would require about 5 volts more, in addition to 3.4 volts, for a maximum swing of 8.4 volts. This is below the battery voltage and is therefore feasible, but may not be practical. There are several limiting factors that must be checked before implementing either modification: 1. capacitance range and response curve of D2 for these voltages; 2. maintaining the supply voltage; and 3. will IC Q20 handle an input frequency of 20 MHz?

The output of the AMP OUT line of IC Q21 is limited to Vdd, the supply voltage from regulator Q9. This is 6 volts, or about 10 MHz of total possible spread, using 1 volt as a minimum figure and linear mode of operation from D2. One possible solution to this limited voltage swing is an amplifier stage with a voltage gain of 2 connected to the battery line. The output would feed varactors D2 and D1-D4 in the front end. This may tune not only the vco over the full 15 MHz, but also the front end to maintain sensitivity. However, it may be impractical to use the unregulated battery voltage. Low batteries and varying load conditions (e.g., audio) may cause voltage fluctuations and instability in the vco.

Still one more option exists. Alternating X2 with a crystal for 45.9333 MHz would shift the transmit beat oscillator exactly 10.0 MHz above the receiver oscillator instead of 10.7 MHz. These crystals would be switched in or out by means of their ground connection. These two crystals (X2 and X2A) would differ by less than 250 kHz, so the bandwidth of the oscillator should not be a problem. The accurate tuning of these crystals is imperative. To tune the front end, an op amp could be used in a voltage summing circuit. (See the suggested circuit in Fig. 2.)

The trimpot would be adjusted to add a preset value to the vcv (varactor control voltage) line to feed the front end (only) when switched in. When not in use, both sides of the pot would be grounded so it would add zero volts for normal operation. Note: X2A may also work on the receive oscillator side if Q1 is broadband enough, and D2 will work on a higher voltage. If so, change R3, 4, and 5 (Fig. 2) to 220k and connect the vcv line to D2 as well. Eliminate the connection to Q7. This will restore memory scan again.

It is my hope that someone else will pick up on these ideas and work them out to completion. In emergencies, such capability to switch between ham and police or fire department channels could prove very valuable.

Good monitoring! ■

Those Amazing Bobtails

—the current-fed connection

The Bobtail antenna system described in the references has created quite a stir. Various combinations of construction methods and feed systems have been suggested through a great deal of correspondence between various amateurs.

A nagging problem has been the lack of a satisfactory explanation of the operation of the antenna when it is current fed. It is hoped that this article may shed some light on this subject and spur others on to try this excellent antenna.

To begin, we need a couple of definitions: 1) Voltage feed—feeding an antenna at a point where a voltage loop (or maximum) occurs. 2) Current feed—feeding an antenna at a point where a current loop occurs.

Antenna theory shows that whenever you have two vertical radiating elements spaced 1/2 wavelength apart, the radiation will be reinforced in a direction perpendicular to a line drawn between the antennas. By using three vertical radiating elements (or four, five, or more) all spaced 1/2 wavelength apart, the radiation will be reinforced in the same directions as before, approximately proportionally to the number of radiating elements. Such an antenna is known as a curtain. Because our antenna has only three elements, it is known as a short, or Bobtail, curtain.

Curtain antennas of the type described are bidirectional, with radiation patterns that look like elongated figure-eights viewed from the top of the antenna looking down. The figure-eight pattern extends perpendicularly from a line drawn between the antennas, and when many elements are phased, the figure becomes longer and skinnier and the result is a bidirectional beam: a *broadside array*.

In order to understand the operation of the Bobtail curtain antenna, one must consider the antenna currents in terms of their magnitude and phase relationship. Ideally, in an antenna of this type, all radiation is from the vertical elements, and little or no radiation occurs from the horizontal sections (flat-top portion) because these exist merely to achieve the proper phase relationship between the vertical elements.

Heretofore, the Bobtail has been *voltage* fed by means of a coupling network attached to the bottom of the center element, although it is possible, if desired, to attach the coupling network to the bottoms of either of the vertical end elements.

For many reasons, including convenience, ease of matching, simplicity, elimination of coupling networks, and other factors, it has been considered desirable to find another way of feeding the Bobtail, and such a method has been reported as having been used with success by a number of different amateurs. Here's how it works:

In Fig. 1 observe that the Bobtail array, as before, consists of the three quarter-wave vertical elements at A, B, and C. The two end elements at A and C are essentially a portion of the flat-top and connected directly thereto.

The center vertical element is separated from the horizontal flat-top portion by a small insulator at G, and the conductors of a coaxial feedline are attached to the flat-top and to the vertical element, across the insulator, with the center conductor connected to the vertical, and the braid connected to the exact center of the flat-top, at B.

Vertical element A is separated by 1/2 wavelength from element B, and vertical element B is separated by 1/2 wavelength from vertical element C. Flat-top sections A-B and B-C act as phasing lines to make the current relationships in the antenna come out properly, i.e., the current in section A-B is 180° out of phase with the current in B-C, and therefore they cancel.

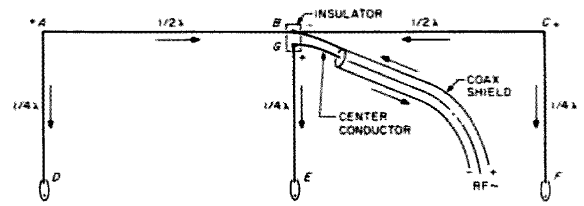

Fig. 1. The current-fed Bobtail.

The currents in the vertical elements are in phase and add because the current is traveling in the same direction at any given instant (but the currents are not equal in magnitude). The reason for this is that the vertical elements are each only 1/4 wavelength at the operating frequency. The current divides between the vertical elements in a ratio of two to one.

In order to satisfy the phase requirements, the magnitude of the current in the end elements must equal the magnitude of the current in the center element. Since there are two end elements and only a single center element, the current in the center element must be twice that in each of the end elements.

If you study Fig. 1, you will notice that for a particular given half-cycle, the + and − signs are as shown, changing sign at each 1/2-wave point. We have assumed the feedline to be exactly 1/2-wavelength long. The arrows between the plus and minus signs show the direction of current during the particular half-cycle we've chosen to illustrate. During the next half cycle, note that the polarity at each of the half-wave points will change and the current arrows will reverse direction, but also note that, once again, the currents in flat-top sections A-B and B-C will cancel. The currents in the vertical elements will again add in-phase in spite of the fact that their direction is reversed. Thus, on each half of every full cycle the vertical elements always add in-phase and the flat-top sections always cancel.

Interesting Side Notes

If you turn a current-fed Bobtail upside down, it looks like a much more familiar antenna system. By eliminating the phasing line (flat-top) and substituting ground, you have three 1/4-wave verticals spaced a 1/2-wave apart. This is very common practice in antenna systems, for example, in the broadcast industry for directional beaming.

The disadvantage of all but perfect ground systems is the resistance loss in imperfect conductors. Consider, now, what happens when we use the Bobtail array: The "ground" becomes the horizontal wire or flat-top—nearly loss-free compared to ordinary ground and, better still, elevated above earth by at least a 1/4 wave.

What this means is that the antenna becomes more efficient and the radiating portion is raised. The high-current portion of an antenna is the portion which does the biggest share of the radiating and that is why it is best to get it as high and as in the clear as possible. The Bobtail array accomplishes these things and, therefore, is a good antenna compared to one in which the radiating portion is low and the losses in ground resistance are high.

One more item. Radiation from a Bobtail is *vertically* polarized and therefore, when placed as in the configuration shown in Fig. 1, exhibits not only gain, but a very low angle of "take-off," as is typical of many vertical radiators. Hence, it's a good DX antenna.■

Shoot the Moon!

—visual tracking for your EME array

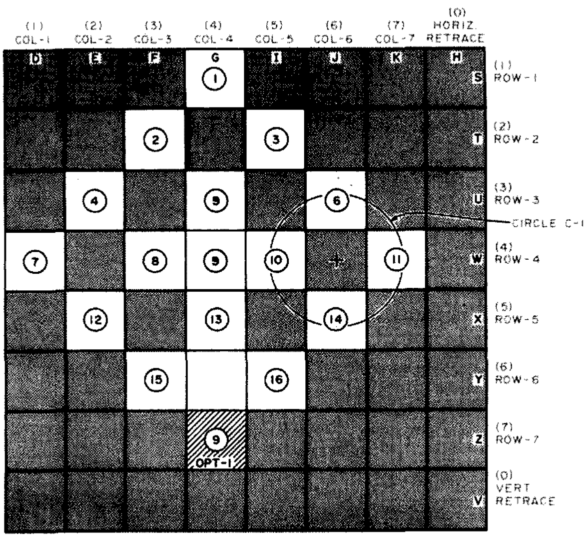

Fig. 1. Video monitor screen presentation. White squares with numbers are the maximum number of squares that can be lit. Dark areas are never lit. One possible moon image is shown by circle C-1. This would light squares 6, 10, 11, and 14. Adjust your lens or lenses for approximately this kind of spot size. The numbers correspond to the LDRs in Fig. 10.

Is your OSCAR or EME array all automated for tracking? Mine is, but I still wanted a means of visually tracking in a manual mode. This article details the simple "moon" camera I came up with to look at the moon while I stayed comfortably in my basement (Indiana winters get cold!). It also makes a fine motion detector or low-resolution surveillance camera.

Take a look at Fig. 1 for a moment. What I have is the screen of a TV set or, in my case, a video monitor. There is no reason why you can't feed the video output of my simple camera to one of the TV game modulators and pipe it into any TV set as rf on whatever channel the game modulator outputs on.

As shown, the spot or image of the moon has been concentrated into a round circle that just illuminates one or more of the photosensitive devices (more on them later). Whenever light shines on these devices, their resistance is greatly lowered and I sense that change to light a square on the monitor screen. In order to have the different positions on the screen represent different aiming positions of the antennas, there are two main requirements.

The first and easiest is that the camera be physically boresighted to the antenna. That's just a fancy way to say that it has to be aligned to look where the antenna is looking.

Secondly, the photo devices must be arranged in an array that duplicates

what you want to see on the screen and then scanned in step with the monitor scanning. These last two requirements are met easily using the circuitry and board layouts provided by this article.

Since I have started you out at the photo-sensing end, let's begin there on the circuitry and boards. The first thing you will notice is all the boards are round instead of square or rectangular. This allows for mounting in a round enclosure (details later, under Mechanical Assembly). The first board to consider is the LDR Board, shown in Figs. 2 and 4. I used light-dependent resistors (LDRs) as photo devices; mine are about ¼" in diameter at the light-input end. This allows the array of 16 LDRs you see the pattern for to fit easily on my round board.

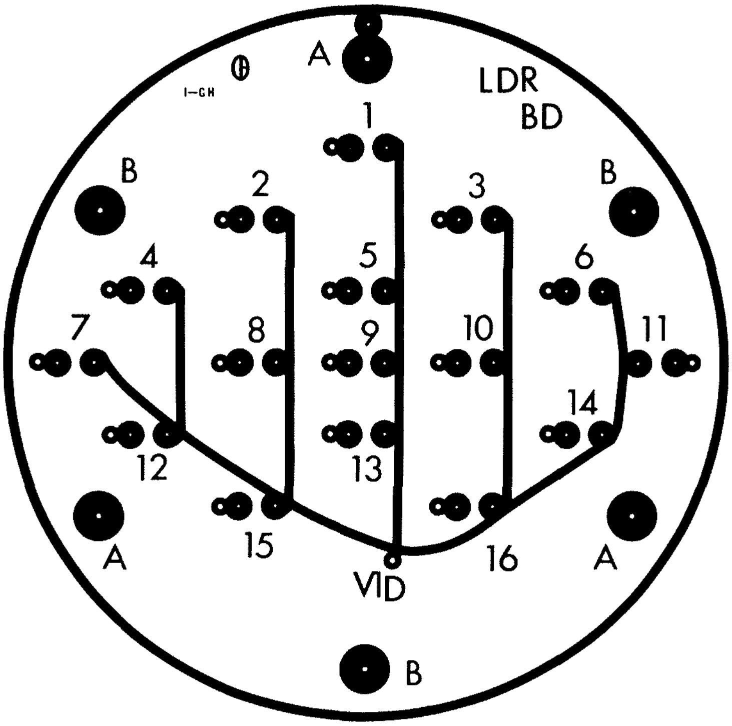

Fig. 2. Foil side of LDR board.

To mount the LDRs in the board, you need sockets of some kind. This avoids direct soldering and the possible altering of the resistive characteristics of the LDR. I highly recommend an item called a matrix pin by AMP, Inc.; it is their part number 380598-2. These are single-terminal push-in sockets and are sold by many parts houses and the magazine advertisers. Just drill out the circles to hold the sockets of your choice and load the board up as shown.

All leads come to the board from the copper side and pass through their holes, leaving a small amount of the stripped lead on the copper side to solder to. When this board is complete, there should be seventeen leads 4" to 5" long coming off the copper side. (Use different colors to avoid confusion.) 16 leads are to one side of each LDR, and one lead is common to all LDRs and is called the video lead (VID). There is really no easy way to test the board at this point, so set it aside and go to the counter chain schematic in Fig. 3. The corresponding foil and component sides are shown in Figs. 5 and 6.

The counter chain should go together quickly, and it can be checked out fully when completed—less any other boards. Load the board as shown and then check the test points using a frequency counter or oscilloscope at each test point against Table 1. The starting point is at the 555 IC, as this is the master clock. It should *run* at 122.88 kHz, and you adjust to that using the PC board thumbwheel pot, Ra. The set you use for a monitor will more than likely lock up (have steady sync) if the clock is from 122.0 to 123.5 kHz, but you may have something called flutter due to a difference between your divided-down vertical (59.57 to 60.3 Hz in the clock range just given) and the proper 60-Hz rate used to avoid beats against the power line 60 Hz.

The wide range of tolerance on most TV sets allows you a lot of leeway

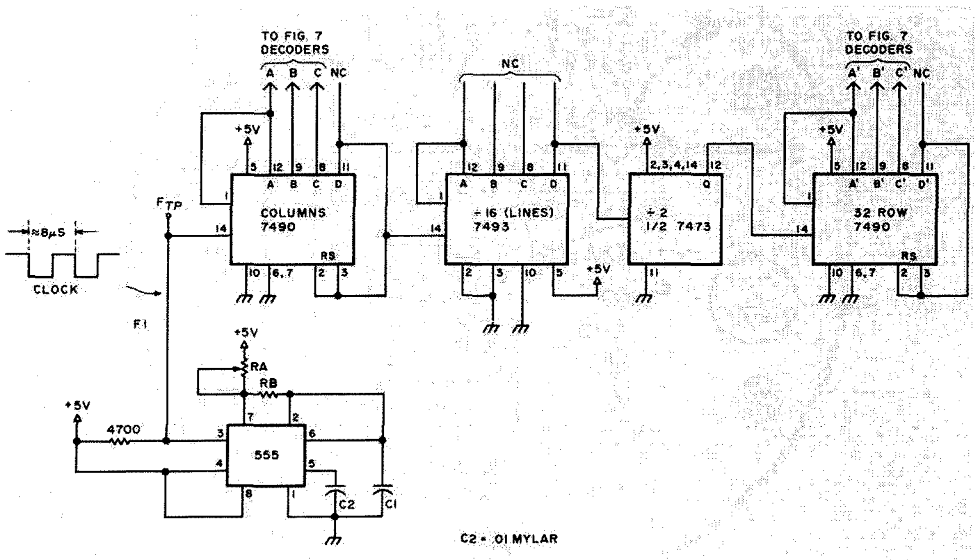

Fig. 3. Counter chain. Set for a frequency of 125 to 126 kHz at F_{TP} test point. For this application, C1 = 220 pF, Ra = 10k thumbwheel PC pot, Rb = 18k, ¼-W fixed resistor. General formula is: f = 1/T = (1.44)/Ra + 2Rb) × C.

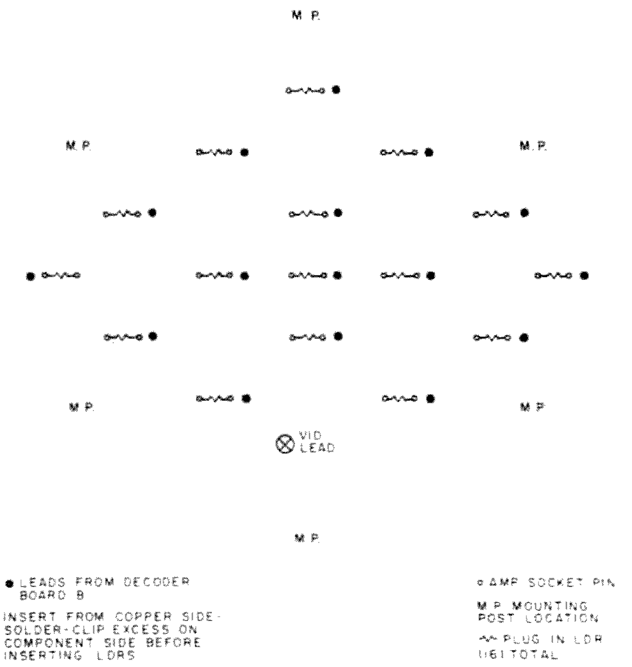

Fig. 4. Component side of LDR board. M.P. designates mounting post (threaded spacer) locations. Use alternate locations between any board pair, thus only three spacers looking like a triangle between any board pair. Small circles are socket pins for LDRs. Solid dots are leads from decoder board B and should be inserted and soldered from the copper side and excess lead on component side clipped off flush with board. Resistor symbols are LDR locations.

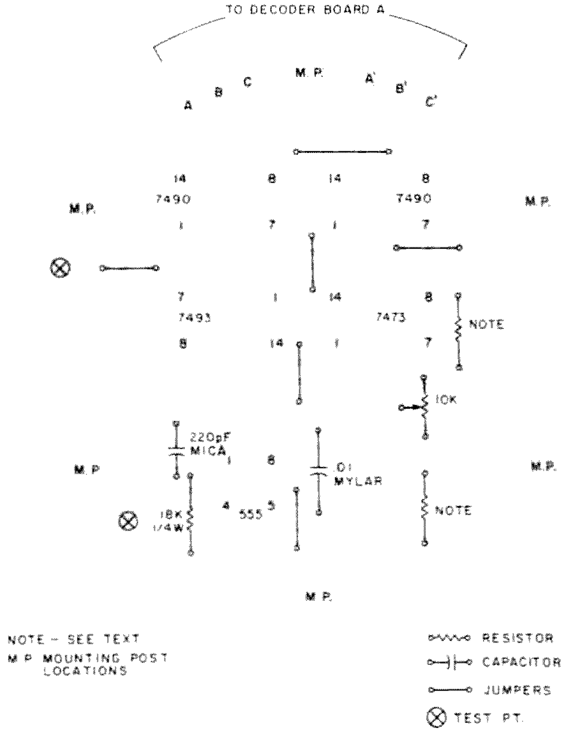

Fig. 6. Component side of counter chain board. Standard schematic symbols are used to show component mounting locations. Solid lines connecting dots indicate jumper leads. Circled x indicates test point.

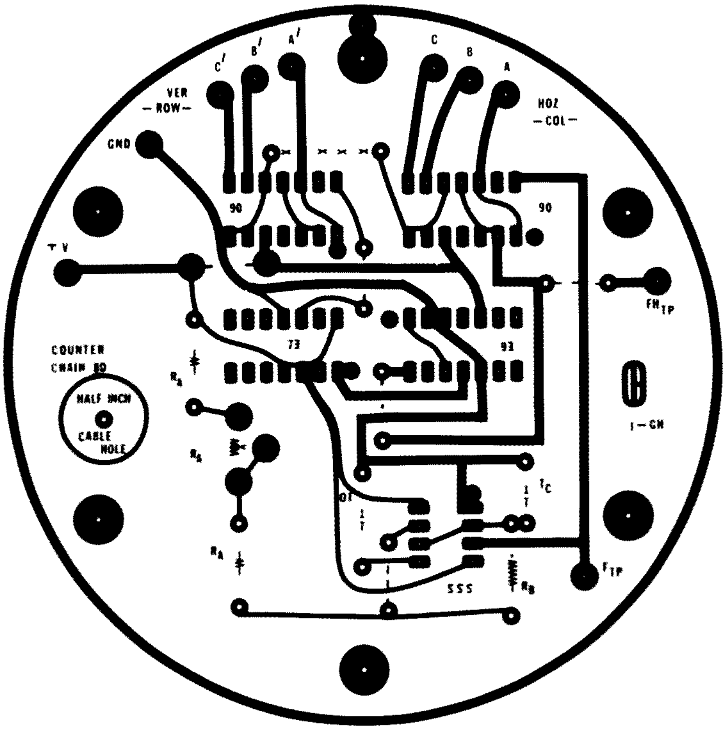

Fig. 5. Foil side of counter chain board.

in the setting of Ra where the set will lock up and look alright. If you can't get things as good as you want using a 10k pot for Ra and jumpers in the fixed Ra positions, a smaller pot can be used along with fixed resistor(s) to allow Ra to effectively tune slower. You would have to find the two extremes of Ra settings that create a locked-up picture, measure the resistance of Ra in each case, and use the difference as the new Ra value. Then fixed resistors make up the jumpers. Remember, the total must be 10k.

Example: If the set locked up alright on resistor Ra settings of 2500 Ohms to 7500 Ohms, use a new Ra of 5k and one fixed resistor of 2500 Ohms in either fixed Ra (jumper) position. Your new range then becomes 2500 to 7500 Ohms.

Ignoring the +V and ground leads needed by all boards except the LDR board, there are only six leads leaving the counter chain board (A, B, C, A', B', C'), and they all go to the points lettered the same on

decoder board A (Fig. 7). If these points are outputting according to Table 1, the 7442 decoders (IC1, IC2) will decode the BCD line codes into one of ten outputs. Since the D line is not used off the 7490s, the 7442 becomes a one-of-eight decoder. In IC1, positions 1 to 7 represent seven vertical columns across your monitor screen. Position 0 is left as horizontal retrace and is covered on the video/sync board. IC1 runs the sequence of 1 to 7, then 0, 32 times before any change occurs in the vertical scan decoder. This means 32 lines that are identical in vertical coding across the screen. This is accomplished by placing a fixed divide-by-32 chain between the horizontal and vertical counters.

In the case of the number 1 LDR, if light is shining on it each of the 32 lines will go white from a black screen as it scans over the column position 4 (center). When this happens 3 times, a white square is formed at the top center of your screen. When you have all your camera boards together but no optics or lenses over the LDRs, the monitor screen will light white squares in the same pattern as the LDRs are laid out on the board if

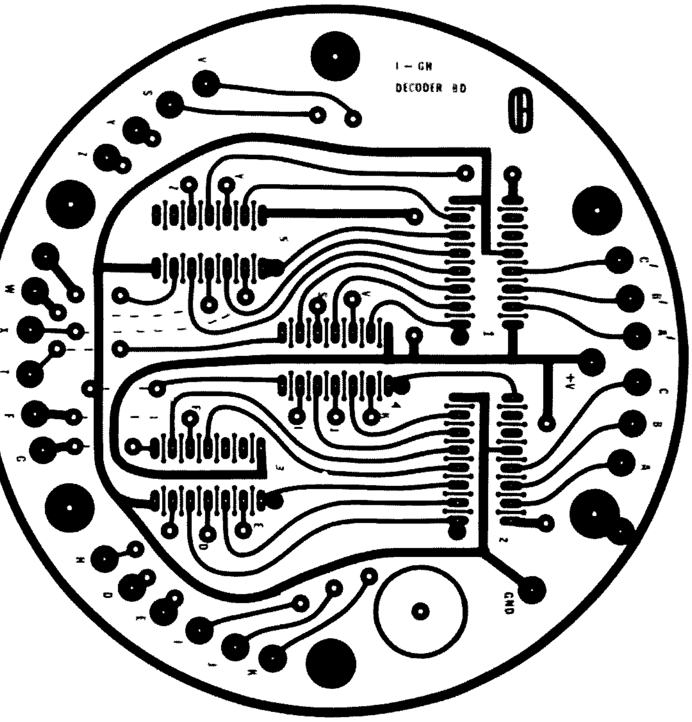

Fig. 8. Foil side of decoder board A.

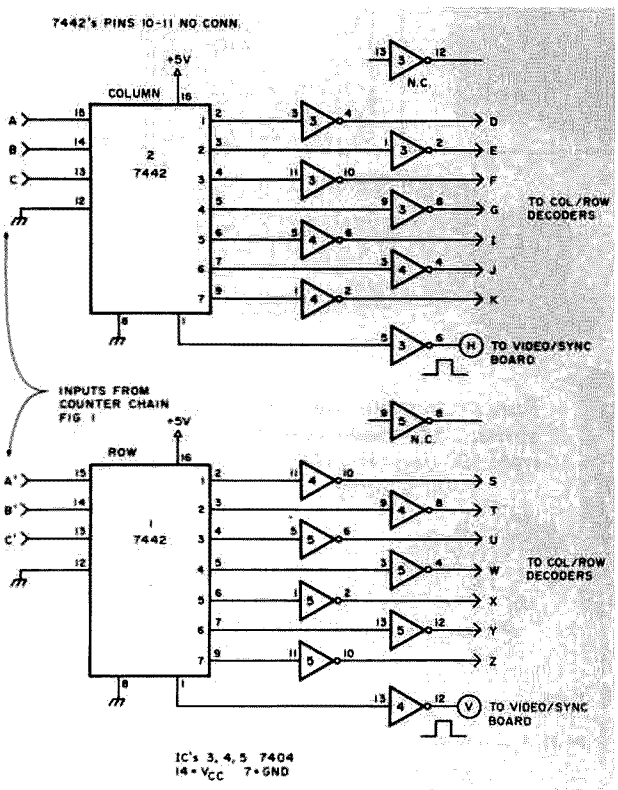

Fig. 7. Schematic of decoder board A.

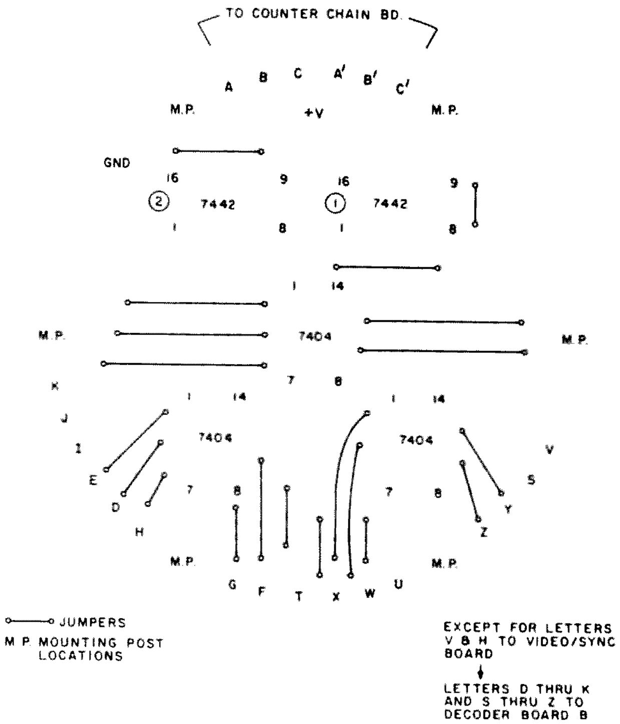

Fig. 9. Component side of decoder board A. Letters V and H are leads to video/sync board. Letters D to K and S to Z are leads to decoder board B (except V and H). Solid lines connecting dots are jumpers on component side.

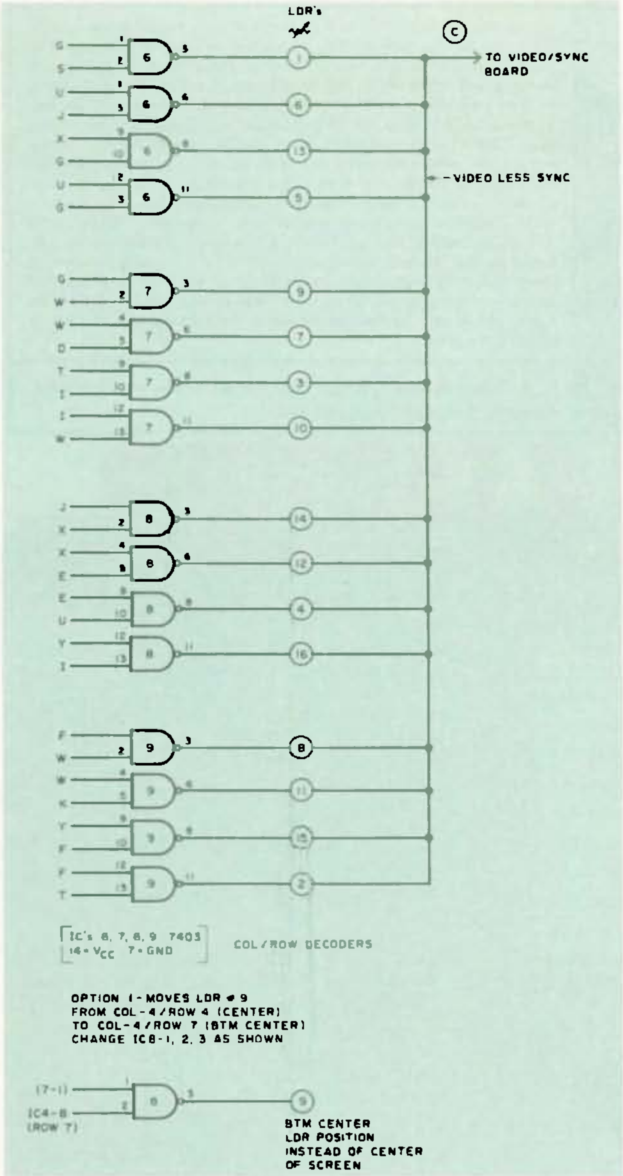

Fig. 10. Schematic of decoder board B. Option 1 moves LDR #9 from column 4/row 4 (center) to column 4/row 7 (bottom center). Change IC8 pins 1, 2, and 3 as shown, and load LDR at bottom center.

light is falling on all the LDRs. This will be a final check that all is working, before the mechanical assembly.

The row decoder (IC2) does the same job as the column divider (IC1) but at a slower rate, to handle horizontal rows. Therefore, it advances one position after each 32 horizontal lines. This happens seven times, forming 7 horizontal rows of 32 lines each. If more LDRs and decoding were used, the camera has a possible 7 × 7 or 49-position resolution. The complexity is not worth it, and the camera functions just fine using only 16 of these 49 possible locations. This is accomplished by allowing the focused moon image to be larger than one square of resolution and using multiple lit boxes to show where the image is relative to center screen (on target). A perfectly aimed antenna will produce a white + sign at the center of the monitor screen.

IC3, IC4, and IC5 are merely inverters to get the low 1-of-8 outputs of the 7442s back to highs that can be gated together in further TTL logic. Figs. 8 and 9 show the foil and component sides of decoder board A.

The last of the decoding occurs in Fig. 10, decoder board B, where 7403 gates are used to detect which of the 49 squares the monitor is scanning over and enable the proper LDR for that segment. Figs. 11 and 12 show the foil and component sides of decoder board B.

For the positions that have no LDRs, as you will see more clearly next on the video/sync board, there will be no LDR enabled and the video (VID) line will be at or very near +V. This +V on the VID line will represent a black screen on the monitor in the final video composite. For those squares that have an LDR sensor, each has a corresponding 7403 gate section. When the gate is enabled, the open collector output tries to pull +V down to ground through a load resistor. All the LDRs are in parallel by the video line, but only one at a time can be considered in the circuit—the one enabled by the scanning chain.

Going briefly to point C on Fig. 13, the video/sync board, you will see a 10k resistor to +V in the base circuit of the first video stage. The circuit is really a voltage divider consisting of that 10k at all times, in series with either (1) an LDR that is in series with the output transistor of its 7403 gate to ground, or (2) the 10k alone with no enabled LDR for those positions not having LDRs.

Remember, I said +V on the VID line meant a black screen. Automatically, you have 33 positions representing no LDRs and a black screen. In the 16 positions having LDRs, the LDR represents the lower resistor in a voltage divider and as such will cause the voltage at point C to be very close to +V (LDR off—no light), or very close to ground (LDR on—light shining on it). My LDRs swing from several megohms (dark) to about 400 Ohms (light). That means the voltage divider changes from (1) +V through 10k through megohms to ground, causing the junction of the 10k and LDR to be very close to +V, to (2) a series of +V through 10k through 400 Ohms, causing the junction of the 10k and LDR to be very close to ground. This junction voltage controls the base of the first video stage.

Following through the video for an example of one LDR with light on it, the VID line and point C will be low or near ground. The first video stage is just an emitter follower, so no inversion occurs and the base of the second video also will be low and the transistor at or near cutoff. When it is cutoff, the collector rises to at or near +V, and this represents white on the screen.

The last stage is also just an emitter follower to allow enough current to drive a 75-Ohm cable and the 75-Ohm load presented by either the game modulator or the video monitor input. If the monitor has a gain or video drive control, jumper A to C in the last video emitter circuit and omit the onboard gain pot, RL. If the monitor has no control or the game modulator no input gain adjust, use RL and jumper B to C to allow some means of adjusting overall composite video level.

The base of the final video stage has control from two more points that should be covered here. The two transistors with H and V for inputs are the sync mixer and make up the

final composite video. Each time the H line goes high (every horizontal line, position 0) or the V line goes high (every vertical scan or field, position 0), the base of the final video is dropped to approximately 0.2 volts, or close enough to be called ground. This is sync-voltage output in my camera.

If the video example were reversed, using a dark or absent LDR position, the second video stage can turn on only to the point where its collector is at 1.4 volts. This is caused by the two diodes in its emitter for 0.6 volts apiece and the 0.2 volts from emitter to collector on the second stage. This 1.4 volts becomes our black level, and allows for the normal video composite of sync being blacker than black. If you consider my composite video as 0.2-volts sync, 1.4 volts-black, and 5.0-volts white, then divide it down with the level control, you will end up with video composite of very close to the standard of 1.0-volt video, 0.4-volts sync. It at least seems to be close enough for a perfect picture with stable sync, and I felt that trying to get any closer was not worth the time or extra components. Foil and component layouts for the video/sync board are shown in Figs. 14 and 15.

That about completes the electronics package, and if you have a power problem, the 74Cxx equivalents can be used for all the TTL devices except the final 7403 decoders. The 555 is running well below its maximum +18 volts, but seems content and quite stable on +5 volts.

Mechanical Assembly

The area of mechanical assembly will vary, as with most ham projects, along with its uses. For that reason, I'll outline how I did mine and you can carry on or modify from there. As illustrated in Fig. 16, the housing on my camera is PVC plastic pipe! That's why all the boards are round and separated by three spacers between each board. You can, thereby, build up a board-over-board sandwich by skipping every other hole of the six given per board to set the spacers on.

Looking straight into the LDR board, it is spaced from the board below it by 3 spacers in a triangle. The next board below, by 3 in an inverted triangle, and so on. I used 4-inch i.d. black pipe, and would suggest that whatever you use be black inside to avoid light reflections and stray light. You can buy end caps for the pipe, and I used one as is on the rear of the camera. It was stuck on with rubber cement for easy removal. One hole in this cover allowed the RG-59 feedline to exit through, and a second would have to be provided if the on-board level control is used—I did not use it.

The front cover I made from another end cap, but I sawed off the entire lip from the horizontal center line down. This allowed me to add small aluminum brackets to one side. To the

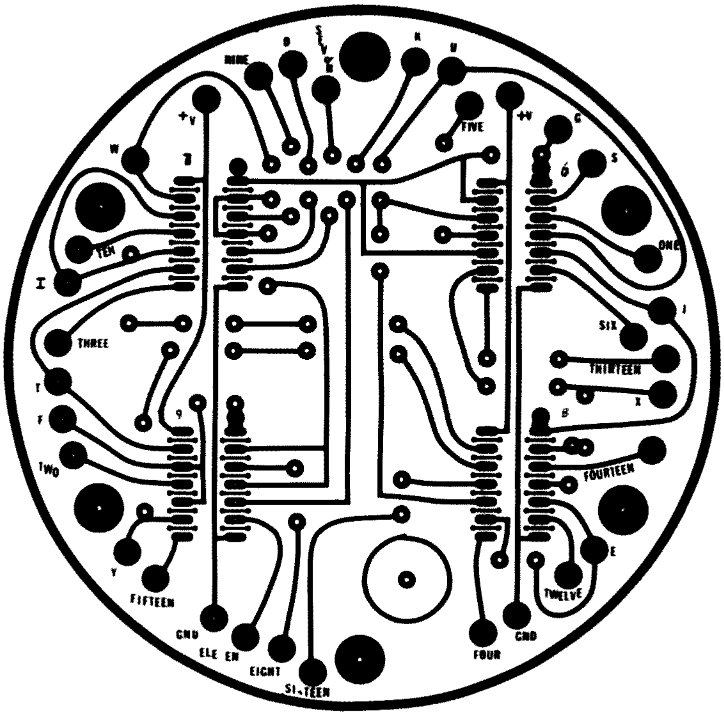

Fig. 11. Foil side of decoder board B.

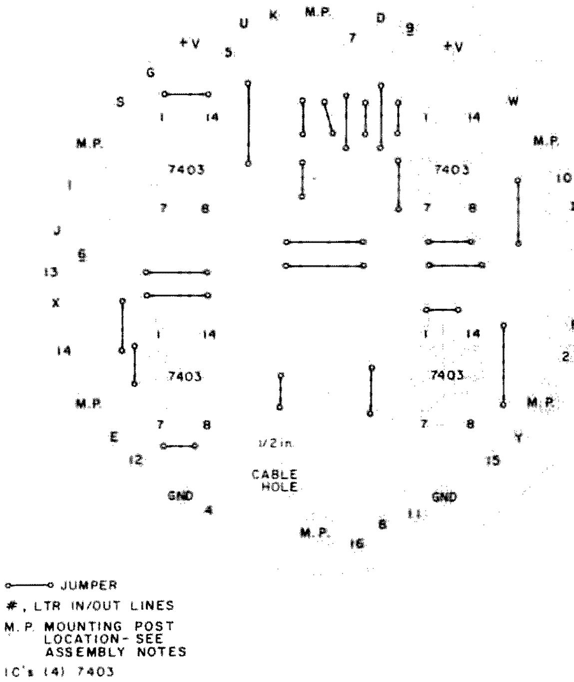

Fig. 12. Component side of decoder board B. Numbers and letters indicate proper placement of input/output leads to other boards. Solid lines connecting dots are jumper leads on component side.

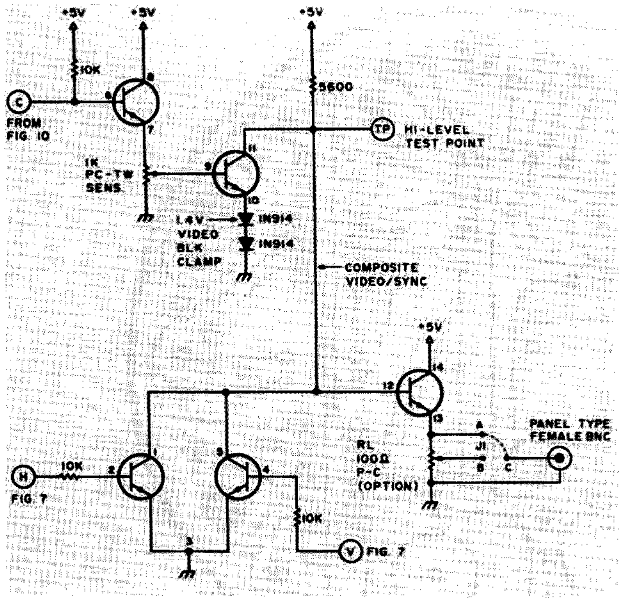

Fig. 13. Schematic of video/sync board. All transistor devices shown are small-signal NPN devices in an RCA IC, CA3046. Numbers shown around the e-b-c of devices indicate pin numbers of that IC for reference and troubleshooting. Note: If cable is terminated in 75 Ohms at the monitor or a drive-level pot (usually 50 to 100 Ohms in monitors), use J1 from A to C and omit pot RL. If no drive level is used on your monitor, jumper B to C and use RL as your drive control to prevent overload.

bracket is attached a rod that runs down the side toward the rear to a small, sealed, metal box that holds a 4-rpm dc motor I had lying around. It is much like the ones the advertising signs use, and I think it was for 6-V dc battery operation. Plus 5 volts runs it just fine, if a bit slow. This allows me to remotely rotate a "lens cover" of sorts on and off the end of the pipe to keep rain, snow, dirt, etc., out of the lens area.

On the topic of lenses, or optics, I am still trying for a better setup, but one of my prime criteria was that it be cheap. After all, I'm trying to avoid using an SSTV or FSTV monitor camera because of cost, so why use a camera lens that costs more than the system electronics? So far, the best combination I have found is with dime-store magnifying glasses with their handles removed.

I fixed-mounted one that was right at 4 inches o.d. at the center of a 6-foot piece of PCV pipe, and that allows me to slide the electronics in and out towards it from the rear. I also have a 3.5-inch lens mounted in a 4-inch collar that I can slide in and out from the front of the pipe to form a compound lens system. That is the area of experimentation at the moment, and I don't mind admitting my physics classes were too long ago. Optics was never really my bag, nor was photography, so all help offered will be gratefully accepted.

The limitation of this system would seem to be use only during full moonlight, but that depends on the response of the photo device you use and the lens system you end up with. As it stands now, I can track in some very hazy conditions, and even clouds don't confuse things too much. Next to try is a full-blown infrared system, I think!

For all the OSCAR fans who read on when the name was mentioned in paragraph one, I have not gone bananas enough to try visually tracking an OSCAR satellite with the LDR system. However, the same electronics system is being tried, mounted in the same waterproof-type housing with two full caps. The difference is that the 7403 outputs will be used to activate PIN diodes (or similar switching devices) on the downlink antenna system. I am trying to build onto the outdoor, steerable OSCAR antennas something like my Twinlead Terror antenna system (*73 Magazine*, November, 1977, p. 54), and then do the video add-on at the monitor end using the sync/white commands coming down the 75-Ohm cable. The video then would be derived from some form of the receiver agc. I mentioned this earlier, in the Twinlead Terror article (which got titled, "Cheap Ears for OSCAR").

You can do some positively wild things with scanned and electronically-steered antennas when you have only receiver power levels to worry about. It becomes even easier when you have a full-duplex, two-band arrangement like the OSCAR uplink/downlink. The receive antennas scan at a high enough rate to be above audio, so you can easily filter out the switch-rate whine. All you hear is the additive result, but each antenna's agc product is

Signal	Location	Measured Frequency	
1. F_{tp}	555 IC pin 3	122.880 kHz	(for H = 15,360 Hz, V = 60 Hz)
2. A	Column IC pin 12	61.440 kHz	
3. B	Column IC pin 9	30.720 kHz	
4. C	Column IC pin 8	15.360 kHz	
5. D	÷ by IC pin 11	960 Hz	
6. Q	÷ by IC pin 12	480 Hz	
7. A'	Row IC pin 12	240 Hz	
8. B'	Row IC pin 9	120 Hz	
9. C'	Row IC pin 8	60 Hz	

This has the horizontal sync running about 400 Hz low, but allows the vertical sync to be correct to avoid vertical "flutter." This is a compromise to reduce system electronics, but all sets tried pulled in easily to the lower horizontal rate. The following is a representation of the VID line with light shining on all LDRs. L is TTL low pulses. Scope Horz. rate = 1/60 sec per full horizontal scan or about 3 ms per cm on a 6-cm Horz. scale.

HHHLHHHSHHLHLHHSHLHLHLHSLHLLLHLSHLHLHLHSHHLHLHHSHHHOHHHS

H is TTL high, S is sync (app. 0.2 volts), O is option LDR 9

Table 1.

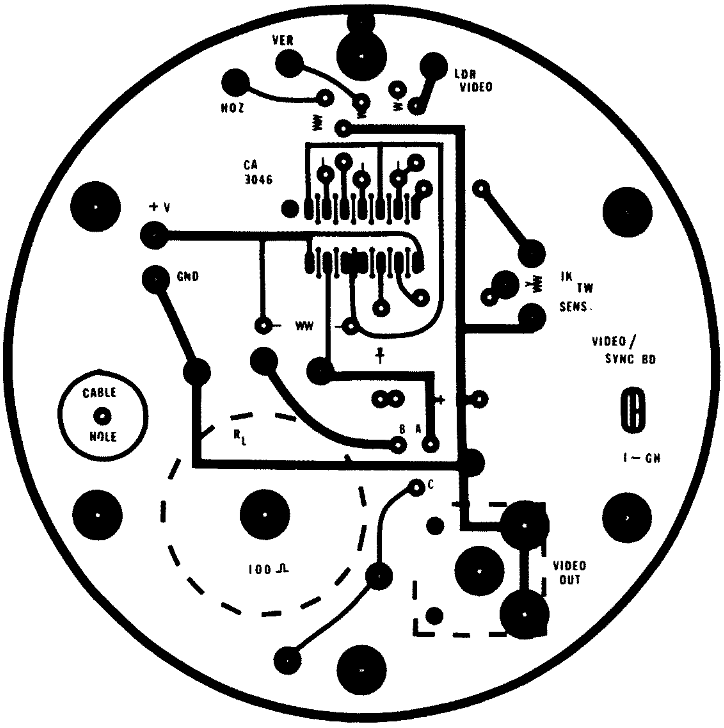

Fig. 14. Foil side of video/sync board.

sampled, and only the highest is used to light the white box on the monitor—sort of a sample, hold, choose-the-highest-figure, and use-for-display system.

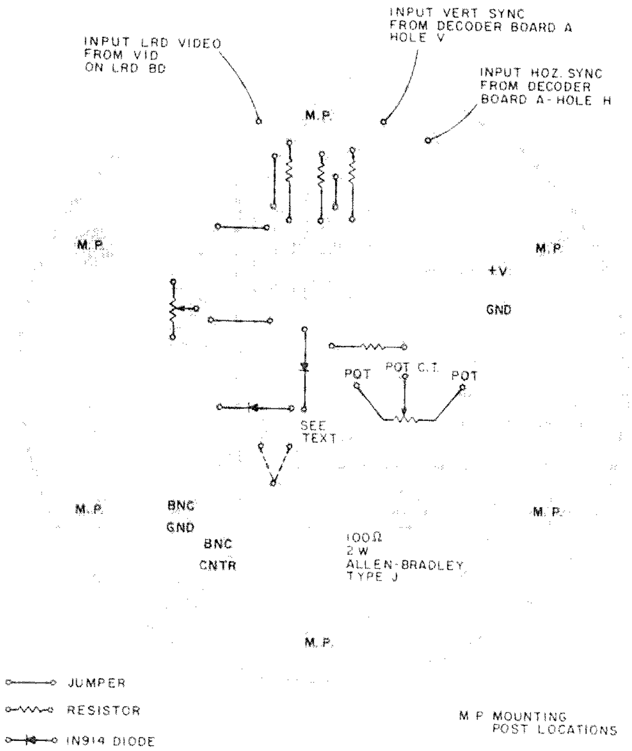

Fig. 15. Component side of video/sync board. Schematic type symbols are used to show loading placement of components. Solid lines connecting dots are jumpers on component side.

I am still deciding whether to use steer antennas to produce center-box white scheme, or sample and display all levels as boxes in the same arrangement in which the antennas are mechanically set up. The latter has the advantage of being able to tell what polarity sense the signal really is, at the antennas, by observing what box(es) are lit the brightest, and to what polarity you have those antennas aligned. It does require small changes in the video stage of the camera, however, so you don't get just saturated white or black off positions intentionally chosen for the EME arrangement.

I have tried several sample-and-hold circuits and antenna positionings so far and have found none to be the perfect result I want. Many such circuits are already around as described in the articles over the past couple of years and 10-meter antennas are easy to build, so you may have your system running before I have mine complete. I am working hard on the EME version at the moment, but should get back on the OSCAR version soon.

The cost of the A-to-D converter IC is quite attractive now, and with my love for digital circuits I am going to try one more sample-and-hold circuit using that type of device. It is an analog in, 3 digits in BCD output device covered a bit further as an antenna readout device for use with CDE Ham 3 rotator controls in *Ham Radio,* January, 1979, p. 56. The device used there is an AD 2020 by Analog Devices, Norwood, Massachusetts.

If there are any questions, please include an SASE, and I'll sure try to help you. If you come up with other uses (surveillance, etc.), please write, as several people have already approached me with ideas beyond what I had in mind. I'll try to act as a go-between as best I can for any new ideas for my camera. Good lookin'.■

CQ MARS de IC-2A

—work new worlds

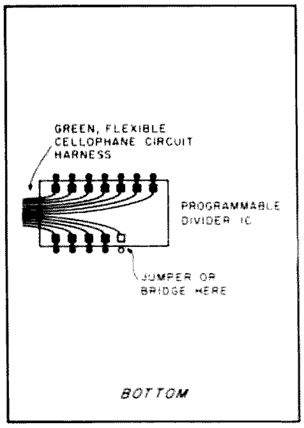

Fig. 1.

Being a group that takes pleasure in passing along useful information to fellow hams, Technical Clinic sends this public information bulletin on the 10-minute frequency modification for the new Icom IC-2A hand-held. The short and simple job will allow operation (depending on individual radio characteristics) from 141.000 MHz to 149.995 MHz.

TC was pleasantly surprised to discover that Icom has made another rig that lends itself to tinkering. This happened while one was on the bench for a product development experiment.

You will need only solder and a low-wattage soldering iron. The two-step operation is as follows:

1. De-solder the brown jumper wire from the MHz BCD thumbwheel switch. This will allow the MHz switch to run through its whole range.

2. Solder a small piece of wire (or form a solder bridge) at the position where the cellophane PC harness terminates at the programmable divider IC, as shown in Fig. 1. This allows the radio to recognize a request for 148 and 149 MHz.

That's it. You now have a radio with MARS/CAP capability which has not had any of its normal operation impaired one bit. It is hoped that all present and future owners of this rig will take full advantage of this mod once their individual warranties expire. ■

SOCIAL EVENTS

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received two months prior to the month in which the event takes place.

ARLINGTON HEIGHTS IL
FEB 7

The Wheaton Community Radio Amateurs will hold their annual hamfest on February 7, 1982, beginning at 8:00 am at the Arlington Park Race Track EXPO Center, Arlington Heights IL. Tickets are $3.00 at the entrance and $2.50 in advance. There will be free flea-market tables, expanded floor space, parking, awards, and a large commercial area, including the new computer section. Talk-in on 146.01/.61 and 146.94. For commercial info, call WB9TTE at (312)-766-1684; for general info, call WB9PWM at (312)-629-1427. For tickets, send an SASE to WCRA, PO Box QSL, Wheaton IL 60187.

TRAVERSE CITY MI
FEB 13

The Cherryland Amateur Radio Club will hold its ninth annual Swap 'N Shop on Saturday, February 13, 1982, from 8:00 am through 2:30 pm at the Immaculate Conception Middle School gymnasium, 218 Vine Street, Traverse City MI. General admission is $2.50 and single tables are $3.00. Talk-in on 146.85 and 146.52. For further information, contact Jerry Cermak K8YVU, Chairman, 3905 Slusher Road, Traverse City MI 49684. An SASE will be appreciated.

MARLBORO MA
FEB 14

The Algonquin Amateur Radio Club will hold an electronics flea market on February 14, 1982, at the Marlboro Junior High School cafeteria, Marlboro MA. Sellers will be able to set up from 9:00 am to 10:00 am and doors will be open from 10:00 am until 2:00 pm. Admission is $1.00. Tables are $5.00 if a written reservation is made before February 7, 1982, and $7.50 for any tables remaining after that date. Refreshments will be available. Talk-in on .01/.61 and .52. For reservations, contact Mac W1BK, 128 Forest Avenue, Hudson MA 01749.

MANSFIELD OH
FEB 14

The Mid-Winter Hamfest/Auction will be held on Sunday, February 14, 1982, at the Richland County Fairgrounds, Mansfield OH. Doors will open to the public at 8:00 am. Tickets are $2.00 in advance and $3.00 at the door. Tables are $5.00 in advance and $6.00 at the door. Half tables are available. Features will include prizes, an auction, and a flea market, all in a large heated building. Talk-in on 146.34/.94. For additional information, advance tickets, and/or tables, send an SASE to Harry Frietchen K8HF, 120 Homewood Road, Mansfield OH 44906, or phone (419)-529-2801.

VERO BEACH FL
FEB 20

The Treasure Coast Hamfest will be held on February 20, 1982, at the Vero Beach Community Center, Vero Beach FL. Admission is $2.00 in advance and $2.50 at the door. Features will include prizes, drawings, a QCWA luncheon, and tailgating. Talk-in on 146.13/.73, 146.52/.52, 146.04/.64, and 222.34/223.94. For additional information, write PO Box 3088, Beach Station, Vero Beach FL 32960.

FAYETTEVILLE WV
FEB 21

The Plateau Amateur Radio Association will hold its fourth annual hamfest on Sunday, February 21, 1982, at the Memorial Building, Fayetteville WV. The doors will open at 9:00 am. Admission is $2.50 and children will be admitted free. Flea market tables are $2.00. All activities will be indoors and will include ARRL displays, forums, exhibits, door prizes, and women's programs. Hot food, refreshments, and free parking will be available. Talk-in on .19/.79 or .52. For more information, contact Bill Wilson WA8YTM, 302 Central Avenue, Apartment 2, Oak Hill WV 25901, or phone (304)-469-9910 or (304)-469-9313.

LANCASTER PA
FEB 21

The Lancaster Hamfest will be held on Sunday, February 21, 1982, at the Guernsey Pavilion, located at the intersection of Rtes. 30 and 896, east of Lancaster PA. Doors will open at 0800. General admission is $3.00; children and XYLs admitted without charge. Each 8-foot space with a table is $5.00 (limited to two tables for noncommercial use and six tables for commercial use). All inside spaces are by advance registration only, and the registration deadline is February 10, 1982. All vendors must set up between the hours of 0600 and 0800; reservations will not be held past 0900 hours without prior arrangement. There will be free tailgating in specified areas outside (if weather permits) on a first-come, first-served basis. Food will be served at the hamfest. Talk-in on 146.01/.61 or 146.52. For advance registration or more information, write SERCOM, Inc., PO Box 6082, Rohrerstown PA 17603.

ELKIN NC
FEB 21

The fifth annual Elkin Winter Hamfest will be held on Sunday, February 21, 1982, at the Elkin National Guard Armory, located one mile from Interstate 77 at exit 85, Elkin NC. Breakfast and lunch will be served at the hamfest by the Foothills ARC of Wilkesboro NC and the Briarpatch ARC of Galax VA. Talk-in on 144.77/145.37, 146.22/146.82, and 146.52. For table reservations, ticket inquiries, or other information, contact Earl Day WB4GQP, 131 Harris Avenue, Elkin NC 28621, or phone (919)-835-3509.

MORRIS PLAINS NJ
FEB 25

The Split Rock Amateur Radio Association will hold its annual equipment auction on Thursday, February 25, 1982, at the Morris Plains VFW Post #3401, located on Route 53 in Morris Plains NJ. Doors will open at 7:00 pm to unload and inspect equipment and the auction will get underway at 8:00 pm sharp. Admission is free. Please limit your items to working electronic equipment—no junk—and make sure any loose parts are bagged or boxed. The club will take a flat 10% commission on all sales of individual items up to $50. Above $50, the club will take a $5.00 commission on each individual sale. All commissions are payable in cash only. There will be refreshments available and the site has plenty of parking. In case of inclement weather, the auction will be held on Thursday, March 4, 1982, at the same location and times. The Morris Plains VFW Post is located approximately 1 mile north of the intersection of Routes 202 and 53 in Morris Plains NJ. For more information, write PO Box 3, Whippany NJ 07981.

GLASGOW KY
FEB 27

The annual Glasgow Swapfest will be held on Saturday, February 27, 1982, beginning at 8:00 am CST at the Glasgow Flea Market Building, 2 miles south of Glasgow on Highway 31E. Admission is $2.00 per person with no extra charge for exhibitors. One free table will be provided per exhibitor with extra tables available at $3.00 each. There will be a large heated building with plenty of free parking. No meetings or forums will be held—just door prizes, free coffee, and a large flea market. Talk-in on 146.34/.94 or 147.63/.03. For additional information, contact Bernie Schwitzgebel WA4JZO, 121 Adairland Ct., Glasgow KY 42141.

VIENNA VA
FEB 28

The Vienna Wireless Society will hold the 9th annual ARRL-approved WINTERFEST™ '82 on February 28, 1982, beginning at 8:00 am at the Community Center, 120 Cherry Street, Vienna VA. Tickets are $3.00 and include one chance for the prize drawing. Prizes will include a Kenwood TS-830S HF transceiver, an Icom IC-25A 25-W mobile 2-meter rig, and a Santec HT-1200 hand-held, as well as accessories and books. Excellent food service will be available. Featured will be dealers' and manufacturers' displays, an indoor flea market, and outdoor frostbite tailgating. Tables are

$5.00 and $10.00. Talk-in on .31/.91 and 146.52. For additional information, send an SASE to WINTERFEST™ '82, Vienna Wireless Society, PO Box 418, Vienna VA 22180, or phone Ray Johnson at (703)-938-8313.

DAVENPORT IA
FEB 28

The Davenport Radio Amateur Club will hold its 11th annual hamfest on Sunday, February 28, 1982, from 8:00 am to 4:00 pm in the Davenport Masonic Temple, Highway 61 (Brady Street) and 7th Street, Davenport IA. Tickets are $2.00 in advance and $3.00 at the door. Tables are $5.00 each, with a $2.00 charge for an electrical hookup (limited number). Hotel discounts, food, and drinks will be available. Talk-in on 146.28/.88, W0BXR. For advance tickets and table reservations, write Dave Johannsen WB0FBP, 2131 Myrtle, Davenport IA 52804.

LAPORTE IN
FEB 28

The LaPorte Amateur Radio Club Winter Hamfest will be held on Sunday, February 28, 1982, at the Civic Auditorium, LaPorte IN, beginning at 8:00 am Chicago time. The donation is $2.50 at the door and reserved tables are $2.00 each. For reservations, write PO Box 30, LaPorte IN 46350.

AKRON OH
FEB 28

The Cuyahoga Falls Amateur Radio Club will hold its 28th annual electronic equipment auction and flea market on Sunday, February 28, 1982, from 8:30 am to 4:00 pm at North High School, Akron OH. Tickets are $2.00 in advance and $2.50 at the door. Sellers may bring their own tables or rent a table for $2.00. There is plenty of space and lots of free parking. Prizes include a Kenwood TS-130S, an Icom 3AT, and an Icom 2AT. A 16K TRS-80 Model III will be raffled at $2.00 per chance. Talk-in on 146.04/.64. For more details, contact CFARC, PO Box 6, Cuyahoga Falls OH 44222, or phone K8JSL at (216)-923-3830.

LIVONIA MI
FEB 28

The Livonia Amateur Radio Club will hold its 12th annual LARC Swap 'n Shop on Sunday, February 28, 1982, from 8:00 am to 4:00 pm at Churchill High School, Livonia MI. There will be plenty of tables, door prizes, refreshments, and free parking. Talk-in on 146.52. Reserved table space of 12-foot minimum is available. For further information, send an SASE (4 × 9) to Neil Coffin WA8GWL, c/o Livonia Amateur Radio Club, PO Box 2111, Livonia MI 48151.

PHILADELPHIA PA
MAR 7

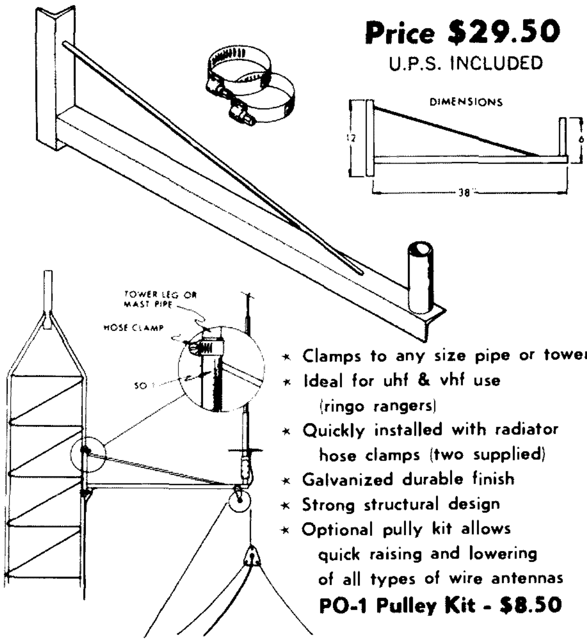
The Penn Wireless Association, Inc., will hold its Tradefest '82 on Sunday, March 7, 1982, at the National Guard Armory, Southampton Road and Roosevelt Boulevard (Rte 1), 2 miles south of exit 28 on the Pennsylvania Turnpike, Philadelphia PA. General admission is $3.00 and a 6'×8' seller's space is $5.00 (bring table) with an additional $3.00 for a power connection (limited number). There will be prizes, displays, refreshments, rest areas, and surprises. Talk-in on 146.115/.715 and .52. For additional information, contact Mark J. Pierson KB3NE, PO Box 734, Langhorne PA 19047.

WINCHESTER IN
MAR 14

The Randolph Amateur Radio Association will hold its 3rd annual hamfest on Sunday, March 14, 1982, from 8:00 am to 5:00 pm at the National Guard Armory, Winchester IN. Tickets are $2.00 in advance and $3.00 at the door. Table space is $2.50 and table space with table is $5.00. Setup times are 6:00 pm to 8:00 pm on Saturday and 6:00 am to 8:00 am on Sunday. For reservations or additional information, contact RARA, PO Box 203, Winchester IN, or phone W9VJX at (317)-584-9361.

MODEL
SO-1 UNIVERSAL ANTENNA STANDOFF

Price $29.50
U.P.S. INCLUDED



- Clamps to any size pipe or tower
- Ideal for uhf & vhf use (ringo rangers)
- Quickly installed with radiator hose clamps (two supplied)
- Galvanized durable finish
- Strong structural design
- Optional pully kit allows quick raising and lowering of all types of wire antennas

PO-1 Pulley Kit - $8.50

IIX EQUIPMENT Ltd. ✓474
P. O. BOX 9 OAK LAWN, IL 60453-0009
DEALER INQUIRIES INVITED (312) 424-7007 MADE IN U.S.A.

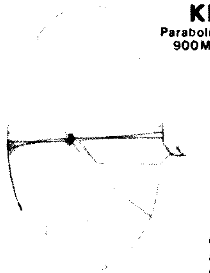
YAESU FT 207 R
ADJUSTABLE AUTOMATIC RESUME SCAN PCB

SAVE MONEY—Add the auto scan PCB to your FT-207R now and scan Memory and the band like the new transceivers, with Automatic Scan Restart on "ACTIVE" channel. Also, you can now set the listening time to suit your own desires, and change it later again and again.

FEATURES:
- Adjustable scan rate—Scan for "BUSY" channel—Set scan to restart automatically in 4 to 12 seconds after channel becomes "ACTIVE".
- Scan Restarts—Immediately with carrier drop—NO MORE WAITING.
- Hold Scan Feature—On any active channel—Automatic Scan Restart
- No PCB changes in transceiver—Simple Installation—Four wires/One transistor
- Scan entire band in approximately 25 seconds
- PCS *built and tested*
- Many more features
- Order WAF PCB S-1. Include $1.20 shipping and handling. NYS residents include 4% Sales tax.

WAF PCB S-1 $29.95 ✓94

QRZ SCAN INC.
11 Pleasant Drive, Rome, New York 13440



KD-44™
Parabolic Reflector Kit
900MHz - 2.5GHz **$54.95**

A low cost, high quality alternative to snow sleds and yagis. 44" diameter, 2 piece durable lightweight *steel const. Includes feed-horn bracket*, pre—cut hardware cloth and all hardware needed for assembly. Excellent for weather satellite and 1296 MHz experimenters!

Our kit also comes in a 2 ft. size with 19 db gain— ONLY $24.50

AMATEUR KITS

2300 MHZ CONVERTER KIT **$36.00**
Includes PC board, parts & instruction manual

SELECTIVE PREAMP **$44.60**
For use with above converter. This preamp can also be used with other manufacturer's boards for improved performance.

VARIABLE POWER SUPPLY **$24.95**
Includes all components, case, overlays, and built in antenna switch.

DELUXE 2300 MHZ CONVERTER KIT **$99.95**
Recommended for experienced kit builders. Dual-stage selective preamp, mixer, i.f. amplifier and no-drift crystal-controlled oscillator

12V STATIONARY POWER SUPPLY **$24.95**
For use with Deluxe Converter. Send 50c for product brochure.

COMING SOON
1691 MHZ WEATHER SATELLITE CONVERTER KIT HOME TVRO STATION WITH POLAR MOUNT

TERMS: Check, Money order, Visa, MasterCard and C.O.D. (Add $2). Allow twoo weeks clearance on checks. Shipping and handling charges C.O.D. by UPS or parcel post unless pre-paid with bank cards. All prices subject to change without notice.

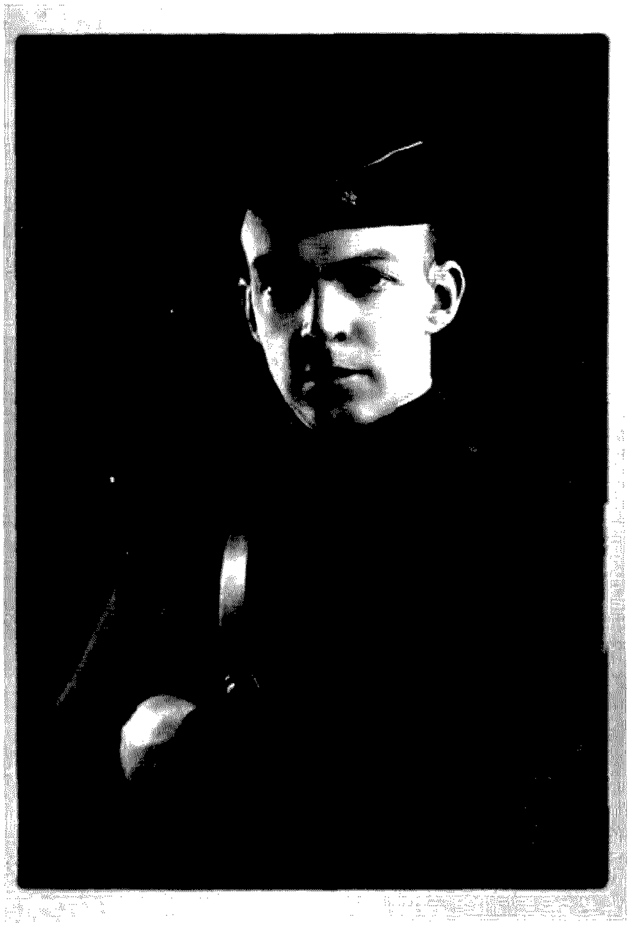
The Father of FM

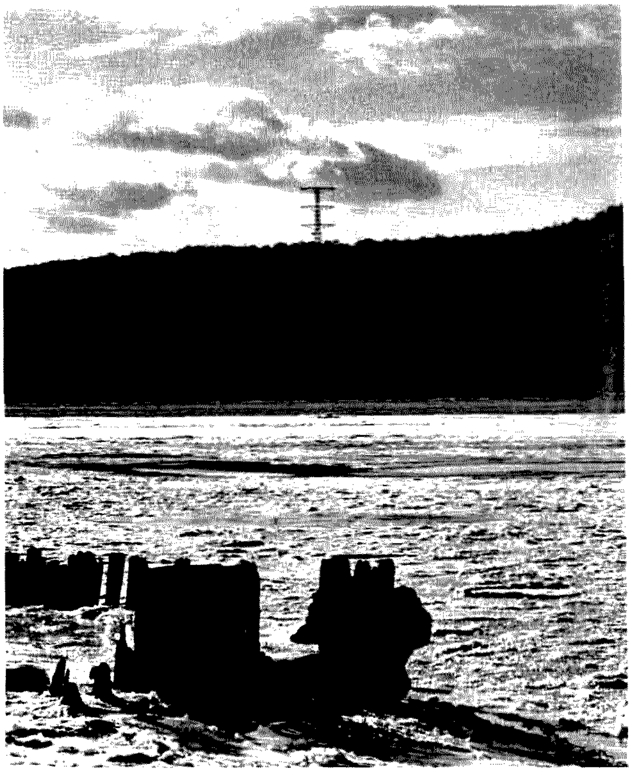
— the tragic story of Major E. H. Armstrong



Armstrong in WWI uniform. (Photo by Bradley B. Hammond)

Jeanne Hammond

Atop the Palisades at Alpine, New Jersey, across the Hudson River from Yonkers, stands a tall,



Armstrong's radio tower atop the Palisades at Alpine, New Jersey, as seen from Yonkers. (Photo by Jeanne Hammond)

three-armed tower. It is accepted as part of the landscape by those who live on the river's east bank and is seen daily by thousands of commuters on Conrail's Hudson Division trains, yet few know what this tower is or how it has affected their lives.

The tower and its accompanying radio station were built in 1938 at a cost of over $300,000 by Edwin Howard Armstrong, pioneer radio inventor, to demonstrate the superiority of his new system of radio broadcasting—frequency modulation (FM). After Promethean battles with the broadcasting industry, which fought to preserve its investment in the established system (amplitude modulation—AM), FM was finally accepted and today is the preferred system in radio, the required sound in TV, and the basis for mobile radio, microwave relay, and space communications.

As little known as the significance of the tower is the man who built it. Armstrong was born in New York City in 1890. When he was twelve years old, the family moved to 1032 Warburton Avenue—known to family and friends simply as "1032"—in Yonkers. The house, which still stands just up from the Greystone railroad station, was declared an historical landmark in 1978 by the Yonkers Historical Society.

Next door, on the north side of the house at the corner of Odell Avenue, was 1040 Warburton Avenue, the home of Armstrong's maternal grandparents. The members of the two families were a gregarious lot, and Howard's childhood was a happy one filled with large gatherings of relatives, many of whom were teachers. Learning was prized. "Quick, boy! How much is nine times five, minus three, divided by six, times two, plus nine?" His great uncle, Charles Hartman, principal of New York City Public School 160, would quiz his nephew to encourage his mental agility.

When Howard was fourteen years old, his father, who was American representative of the Oxford

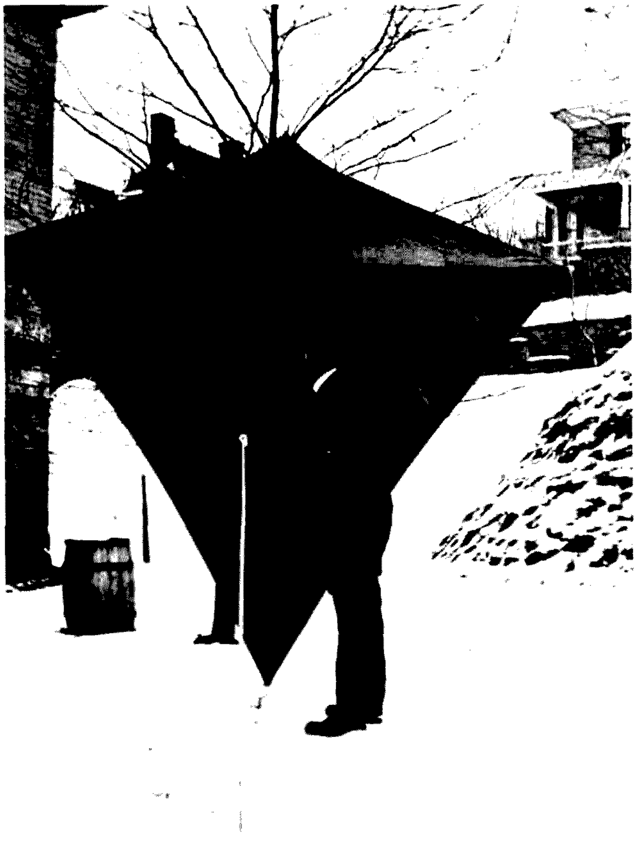
Howard Armstrong, about six years old, with his sister, Ethel.

1032 Warburton Avenue, Armstrong's boyhood home in Yonkers. His earliest experiments were carried out in the cupola on the third floor.

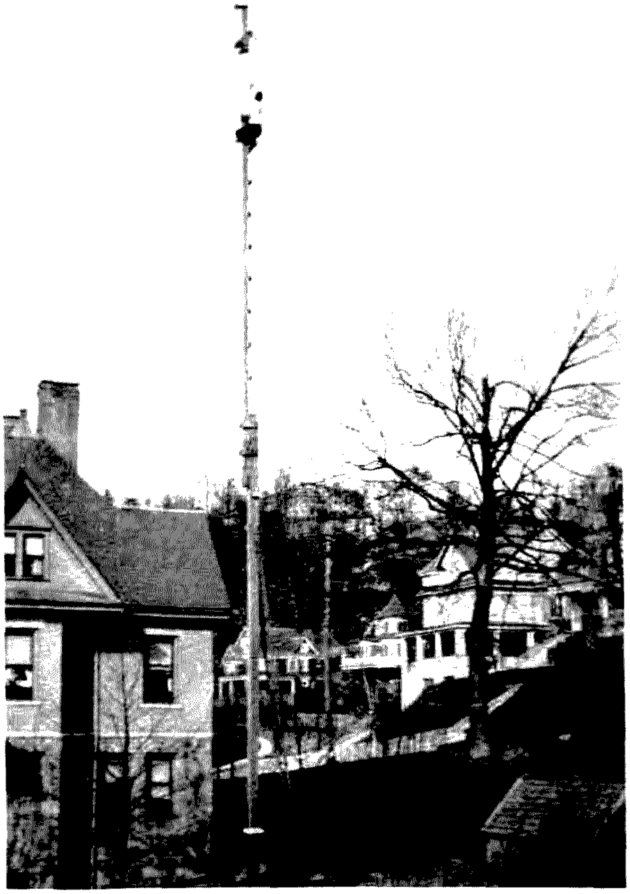
His bedroom/workroom in the cupola looked out on the spot on the Palisades where his radio station would later be. (Photo by Bradley B. Hammond)

University Press, bought him (on one of his yearly trips to London) a book, *The Boy's Book of Inventions.* Reading of Guglielmo Marconi's sending of the first wireless message across the Atlantic so excited his imagination that he determined then and there to become an inventor.

In his attic room in the cupola overlooking the Hudson River, Howard Armstrong began tinkering with radio. In those days, broadcast sound consisted of Morse code signals picked up with earphones. The incipient young inventor set out to make them louder. He was dogged in his search and developed at this early age a capacity for infinite patience in his experiments which was to mark his life's work. "Genius is one percent inspiration and ninety-nine percent perspiration," he



Armstrong constructed large antenna kites which he flew from the upper stories of "1032" in an attempt to improve reception.



The young inventor at work on the "1032" pole.

used to say in later years, quoting Thomas Edison.

Armstrong explored many paths in his attempts to strengthen the sound. Reaching up into the air to better catch the broadcast signals, he flew from the upper stories of 1032 large antenna kites which he had built with the help of his Yonkers friend, Bill Russell. He built a 125-foot antenna pole, the tallest in the area, in the south yard. His younger sister, Edith ("Cricket"), helped in the construction, holding the guy wires and handing him buckets of paint as he swung aloft in a boatswain's chair. Neighbors watched with awe and apprehension. His mother, however, had complete faith in her son. When a neighbor telephoned to say that Howard was at the top of the pole and it made her nervous to watch, "Don't look, then," was her confident reply.

Howard attended Public School 6 in Yonkers and Yonkers High School, and went on from there to Columbia University, commuting on a red motorcycle his father had given him as a high school graduation present. His interest in radio led him to the study of electrical engineering.

In his junior year at Columbia, Armstrong's diligent search for improved radio reception paid off. He invented the regenerative-oscillating, or feedback, circuit which greatly increased radio signals, made them loud enough to be heard across a room and led the way to transatlantic radio telegraphy. His sister, Ethel, remembers vividly the night it happened. "Mother and Father were out playing cards with friends and I was fast asleep in bed. All of a sudden Howard burst into my room carrying a small box. He danced round and round the room shouting, 'I've done it! I've done it!' I really don't remember the sounds from the box. I was so groggy, just having been wakened. I just remember how excited he was."

Major Armstrong's sister, Ethel, and her husband, Bradley Hammond, listen to a crystal set with their evening meal, around 1920. (Photo by Bradley B. Hammond)

Later, another inventor, Lee DeForest, challenged Armstrong's priority for this discovery and the issue was twice argued before the US Supreme Court—which found in DeForest's favor. However, the scientific community has always credited Armstrong for the invention and he received a gold medal for it from the

Billboard in Yonkers dating around 1921. (Photo by Bradley B. Hammond)

Institute of Radio Engineers. Years later, the report accompanying the presentation to him of the Franklin Medal, by the Franklin Institute in Philadelphia, also credited him with the invention of the regenerative circuit.

After graduation from Columbia in 1913, Armstrong worked as an instructor at the college. When the US entered the war in 1917, he joined the Army Signal Corps and rose to the rank of Major—his preferred title for the rest of his life. While in the service, he invented the superheterodyne circuit which amplified even further the sound of radio transmission. This invention brought him into contact with David Sarnoff, who later became President of Radio Corporation of America and whose bright and attractive secretary, Marion MacInnis, he later married.

After the war, Armstrong returned to Columbia where he worked as an assistant to Professor Michael I. Pupin, famed physicist and inventor. When Pupin

died, Armstrong took over his professorship and, financing his own research—his inventions had by now made him wealthy—concentrated on the elimination of static.

In 1933, Armstrong secured four patents which were to be the basis for frequency modulation. This was an entirely new system of broadcasting. Unlike amplitude modulation which varies the amplitude or power of radio waves to transmit sound, frequency modulation varies the number of waves per second over a wide band of frequencies. As static is transmitted by amplitude modulation and cannot break into the wide band of frequencies of frequency modulation, the latter is virtually static-free. Armstrong, who enjoyed aphorisms, liked to quote defeatists who said, "Static, like the poor, will always be with us." He proved them wrong.

The first public broadcast of FM was made in 1935 from the home of his friend C.R. (Randy) Runyon at 544 North Broadway in Yonkers. Runyon was a ham who operated under the call letters W2AG and broadcast from a tower in the yard of his house. The tower and the house are no longer standing. The Runyon living room served as a studio for a demonstration of different kinds of sound that were broadcast to a meeting of the Institute of Radio Engineers at the Engineer's Building on West 39th Street in New York City. Water was poured, paper was crumpled, and live and recorded music were beamed from the Runyon tower to the audience forty miles away.

Although the engineers marveled at the fidelity of the sound, FM did not immediately take off and it would be some time before it would become a commercial success. "If you build a better mousetrap the world doesn't necessarily beat a path to your door," Armstrong said ruefully in later years as he fought for the acceptance of his new system of broadcasting. As a matter of fact, FM was so revolutionary that an entire industry had to scrap its hardware and start over before its potential could be realized. Understandably, the establishment was less than enthusiastic at the prospect.

However, for several years RCA gave Armstrong experimental broadcast privileges in its studio at the top of the Empire State Building. But in 1937, saying that they wished to devote the space to the development of TV, they asked Armstrong to withdraw.

More determined than ever to prove the superiority of FM, Armstrong built his own station in Alpine, New Jersey. The site he chose had been visible to him as a boy from his attic cupola at 1032, and it served his purpose well. It was one of the highest

Interested In DX?

Dick Bash says you need **THE COMPLETE IDIOT'S GUIDE TO DX** *(by Stu Gregg, NF4Z) if:*

....you think IRC means International Red Cross
....you're still working on your DXCC
....you think WAC means a female army person
....you're not a BIG GUN (yet)
....you think the 'BUREAU' is where you put your socks

The Idiot's Guide pulls no punches and doesn't 'snow' you with nonessentials, but it does unlock some DXers' secrets; for example: How to QSL, What to say, Where to place your antenna, How much power to use, Whose awards can you get, Why and When to use SSB or CW, and much more... things that you need to know, and information that Honor Roll members had to learn the hard way.

Dozens of DXers have been interviewed and their suggestions have been included here. Take a tip from the "Big Guns" and use their secrets and tricks.

THE COMPLETE IDIOT'S GUIDE TO DX is available at dealers nationwide for only $12.95, but if you can't stand to wait, rush Dick $15.45 (which will cover First Class postage). If you live in California, please include 84¢ for Sales Tax. *Telephone orders accepted 10 AM-6 PM California time.*

points in the region and had unobstructed space around it for the broadcast of the station's signal.

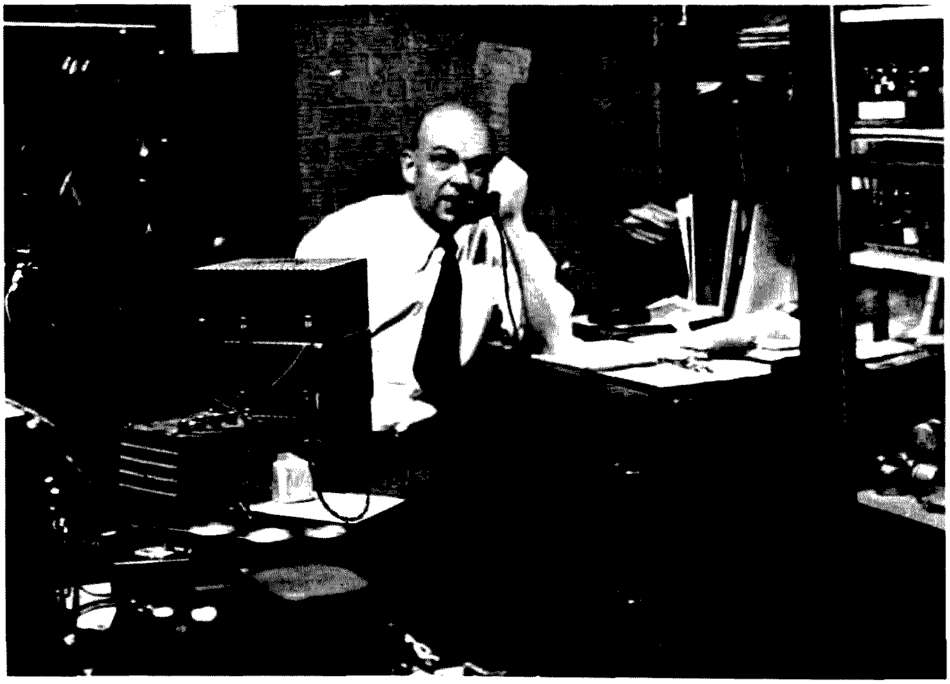
Programs originating with WQXR in New York City were transmitted by wire to Alpine and broadcast first under the call letters W2XMN and later, WE2XCC. Today, the station is owned by UA Columbia Cablevision Company of Oakland, New Jersey, and is operated for closed circuit TV transmission.

During the Second World War, Armstrong devoted himself to military research and allowed the government to use his patents royalty-free. He received the Medal of Merit for his contributions.

After the war, Armstrong turned his attention once more to the promotion of frequency modulation. He saw it grow in popularity as a broadcasting medium as more FM stations went on the air and more FM sets were sold to receive the programs. However, few outside the industry had ever heard of Edwin Howard Armstrong—the man who invented it. Furthermore, manufacturers began to build and sell FM equipment ignoring his patents. Goaded perhaps by the bitter memory of losing his regenerative patent years before, Armstrong became embroiled in twenty-one infringement actions to adjudicate his FM patents. Battling giant corporations with batteries of lawyers used up his resources. Finally, in 1954, ill, disillusioned, and his fortune gone, Armstrong took his own life.

After his death, his widow, Marion, set out to finish what he had started. She continued the lawsuits, sitting in the courtroom each day following the arguments and watching as testimony was given. Her first victory, over RCA in 1954, gave her funds to continue the other suits. In 1967, with the victory over Motorola, she had won all twenty-one and established clearly and decisively that Edwin Howard Armstrong was the inventor of frequency modulation.

Today, the Alpine tower stands as a monument to the brilliant man whose inventions touch our lives every day. His contributions are perhaps best summed up by Lawrence Lessing in his biography of Armstrong, *Man of High Fidelity* (J. B. Lippincott Company, Philadelphia and New York, 1956). "The lonely man listening to music in the night, the isolated farmer hearing nightly the news of the world, the airplane pilot guiding his craft safely through the ocean of the sky, the astronaut now in his capsule gathering in the whispers from space, the earthbound emergency crew contending with some mission of mercy or disaster, the army on the move and the man in his armchair, charmed or instructed for an hour by a great play, a symphony, a speech, a game of ball—all owe a debt to this man who, in some forty years of high fidelity, fashioned the instruments illimitably extending these powers of human communication."■



Armstrong at his desk at W2XMN.

The Art of Listening

—audio accessories explored

In this interesting and highly-readable article, W8FX highlights in a casual, nontechnical way some important considerations in choosing key audio accessories for your station. Whether a licensed amateur or a serious shortwave listener, we think you will be interested in what he has to say about speakers, headphones, tape recorders, and filters for the ham shack.

A high-quality station receiver having attributes of acceptable selectivity, sensitivity, stability, image and spurious signal rejection, and accurate readout forms the heart of any installation—amateur or SWL. Due to cost considerations, front-panel control space limitations, and other factors, not all desirable features can be included. In this article, we look at important audio-related accessories that can be used in tandem with a good set for outstanding performance and versatility. These include proper headphones and speakers, audio filters, and tape recorders. The front-panel phone jack provides the umbilical connection for these devices. The Kenwood R-1000 receiver pictured here has one interesting feature of special interest to SWLs: The function switch at upper left controls a timer used to turn on the radio for scheduled listening or to control a recorder through a remote terminal. (Photo courtesy of Trio-Kenwood Communications, Inc.)

No transceiver or receiver is perfect, and none comes complete with all possible accessories to fill every operating need. The design of such a radio would certainly push the technical state of the art, not to mention that it would most certainly be cost-prohibitive. Various accessories and modifications narrow the gap between needs and reality and allow one to tailor performance accordingly.

There are many receiver audio add-ons one can build or purchase: external speakers, headphones, tape recorders, audio interference filters, phone patches, radioteletype (RTTY) and Morse code readers, slow-scan television (SSTV) viewers, and monitorscopes, to name but a few performance-enhancing accessories.

In this article, we will look at construction and selection considerations for the first four groups listed above. Our review will highlight a number of commercial phone-jack products from the standpoint of their contributions to material reception improvement and making on-the-air operating a more convenient and enjoyable pastime.

Let's begin with the main link between your rig and your ears—the speaker.

Speakers: A Special Breed

Anyone who rates himself or herself a hi-fi buff knows just how important the speaker is to overall audio system performance. Unfortunately, the speaker's importance to receiver or transceiver performance is too often forgotten—by the individual ham and by manufacturers as well. Most amateur equipment made today, whether of domestic or Japanese origin, contains but an undersized, inexpensive, and inadequate loudspeaker. This results in poor audio performance from otherwise excellent equipment. Deficiencies are magnified when equipment is stacked, since the speaker is normally mounted on the top or bottom of the radio where its output will be muffled by the operating desk or other equipment above or below the radio.

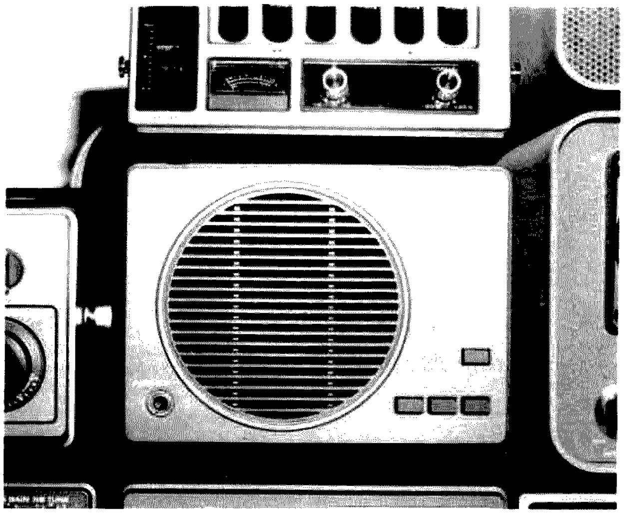
Most radios have provisions for using an external speaker, and I recommend you use one to help attain the overall performance you expect from your set.

Fixed station external speakers. It's a good idea to obtain the matching accessory speaker at the time of the receiver or transceiver's purchase. However, you should be able to use almost any communications speaker as long as the voice coil impedance matches that of your set's output, normally 8 Ohms (4-16 Ohms is the usual range).

Only a *communications*-type speaker should be used, however, as the restricted frequency response of these units is optimized for speech reproduction. Hi-fi speakers, though perhaps of superior overall quality, will unduly accentuate any low-frequency hum as well as high-frequency noise and background hiss.

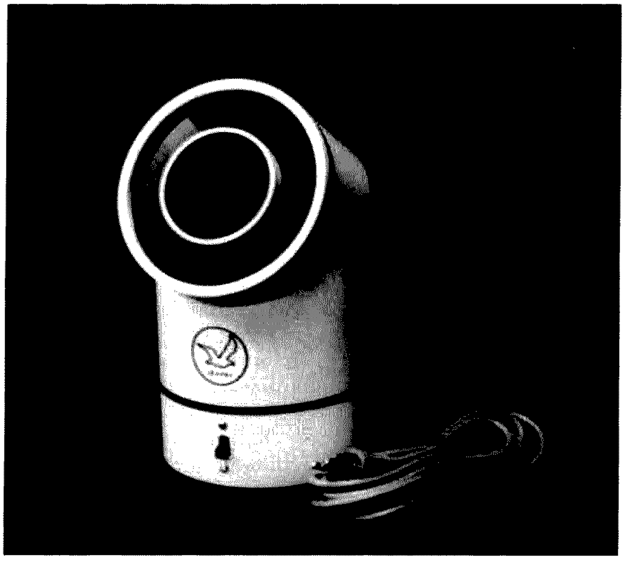
Of late, I've observed that accessory speakers offered by some manufacturers are marginal in size and quality; hooking up one of these units will not produce the improvement one would expect from an external speaker. A possible remedy is to scour the next hamfest or swap meet for one of the 8- to 12-inch boat-anchor speakers of the 1950s and 1960s bearing such names as National, Hallicrafters, Collins, and Hammarlund. These units, if in good condition (voice coil intact and speaker cone undamaged), will run rings around the 4- to 5-inch jobs seen today. A little clean-up, and possibly a paint job, will do wonders to restore a unit to respectability.

You can "roll your own" versions of these increasingly difficult-to-find accessory speakers, too; your effort will likely be rewarded with superior speech quality and intelligibility. Send for the catalog of McGee Radio and Electronics, 1901 McGee St., Kansas City MO 64108. It's chock full of speaker and enclosure possibilities at moderate prices. Select a 6-inch-diameter or greater unit that will handle 5 to 10 Watts of audio power.

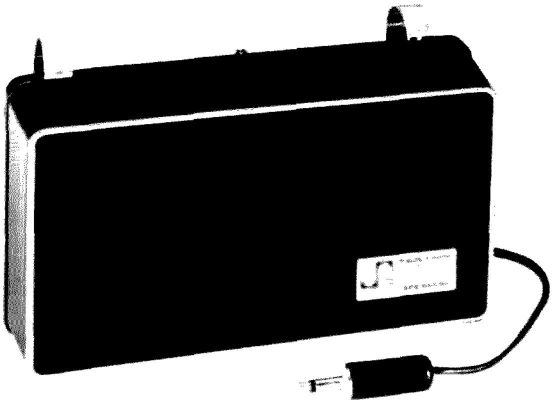


An external speaker is a near-must in view of the minimal speaker usually provided in most amateur gear produced today. The Kenwood SP-180 shown here is designed for use with the TS-180 series of gear; it has a few "bells and whistles" of its own. These include three selectable tone filters and two-channel selectable input. The headphone output can be routed through the tone filters, too.

For the experimentally inclined brasspounder, Skytec offers an unusual designed-for-application CW speaker. This acoustically tuned unit develops virtually single-signal selectivity for excellent Morse reception. The CW-1 combines an acoustic filter resonant at about 750 Hz with a loudspeaker in a small enclosure; a sleeve in the output opening may be extended



Skytec CW-1 speaker is an unusual device that is expressly designed for receiving CW radiotelegraphy. The unit combines an acoustic filter resonant at about 750 Hz with a loudspeaker to closely approximate "single-signal" selectivity. (Photo courtesy of Jim Bowles W6DLQ, Skytec)



Mobile installations can benefit most of all from a carefully-chosen and properly-installed external speaker. Built-in speakers found in most HF and VHF/UHF mobile sets are inadequately sized and positioned to compete with road noise, car sounds, and passenger chatter. Inexpensive CB-type units usually work well, or a specially-designed unit such as this Heathkit® portable twin speaker can be used. Unit includes a visor mount to help direct sound downward to overcome road noise. (Photo courtesy of the Heath Company)

to vary the resonant frequency slightly.

How does it work? In the Skytec speaker, back radiation from a vertically-mounted loudspeaker near the base is deadened by sound-absorbent material. A cylindrical sound chamber (tube) is coupled to the front of the speaker through only a small hole in a plate that otherwise closes the lower end of the tube; the tube's upper end is open to the room. At the frequency at which the chamber length is acoustically one quarter wave long, it is resonant and acts as a matching section between the high impedance (to sound) of the small hole at the speaker end and the low impedance to the room of the open end. Audio energy transfer is very efficient at this frequency but it falls off sharply off-resonance.

Using this special-purpose speaker, desired signals can be peaked considerably (on the order of about 20 dB), while adjacent channel signals still can be heard in the background. This feature allows the band to be conveniently scanned without the need to switch back to the regular station speaker. The speaker can be used in conjunction with standard intermediate frequency (i-f) filters and narrow-bandpass audio-frequency (af) filters, as well. However, the filters must be compatible; that is, bandpasses must be centered on the same frequency. Thus, other filters may or may not be used to advantage with the CW-1, depending on whether their peaks may be set such that the audio pitch that results is within the speaker's response capability.

You also may want to route your radio's output to a remote location such as the workshop, patio, bedroom, or yard. A general-purpose PA type speaker (weatherproof for outdoor use) will usually fill the bill. It's advisable to allow switching between the in-shack speaker and the extension, and also for separately controlling the volume on the remote speaker. An FM wireless mike module also may be used to broadcast received signals to any standard FM receiver in the home or around the yard—more on this possibility later.

You may have noticed that many of the bells and whistles now standard on the latest transceivers and receivers are finding their way into accessories of all kinds. For example, the external speaker for my Kenwood TS-180S is not just a speaker, but a triple audio filter, audio distribution point, and headphone jack box; it can handle the outputs of two receivers, or a receiver and a transceiver. The two af filters are fixed-tuned and push-button-selectable to attenuate either low-frequency (below 400 Hz) or high-frequency (1.5 kHz or 3 kHz up) signals. The headphone output is switchable through the filters, as is the output from either audio source. A line-out jack on the rear apron provides a convenient source of filtered audio for RTTY, SSTV, monitorscope, and other applications where receiver audio is required.

The speaker's fixed filters can't compete with sophisticated "active" audio filters, but can do a good job augmenting existing i-f filtering. The narrowing of the af bandwidth to attenuate the noise component after i-f processing can materially enhance reception.

Speakers for the mobile rig. Practically all mobile amateur transceivers contain small internal speakers. The harsh sound and restricted size and range of most puts a crimp in the quality of reception of *all* signals. Although many radios have the speaker installed on the top of the rig so that the driver will hear it best, most sets aim the speaker downward—the worst possible direction. The set's full audio output is directed where it is largely absorbed by floor mats and carpeting. Even with solid-state equipment, cranking up the audio gain to overcome road noise and passenger conversation can result in microphonic-type squeals from the transceiver due to acoustic coupling back through the rig's innards.

Thus, even more so than in fixed-station operation, an external speaker is clearly desirable. Extension speakers markedly improve intelligibility when positioned and aimed better than the rig's internal speaker and will probably be more efficient than the set's speaker. This fact allows the transceiver's usual 2- to 3-Watt audio stage to be throttled back, resulting in less overall distortion—a real problem with some of the less-weighty mobile rigs, particularly handie-talkies.

A hi-fi speaker, such as that used for automobile FM/AM/tape-deck use, should not be used for the same reasons discussed previously. Instead, a 3- to 5-Watt communications-type speaker should be purchased, one designed expressly for the speech range, 300 to 3000 Hz or so. An inexpensive source of this kind of speaker is the CB market, still flooded with a mass of unsold accessories as well as two-way radios. The quality of CB-type units varies all over the spectrum, but with speakers sometimes going for $4 to $5 at discount and parts-store sales as well as hamfests and CB coffee breaks, it's not too much of a risk to try one out. Other sources of quick-and-easy mobile speakers are the small speaker boxes which are a part of many telephone amplifiers, such as the Radio

Shack 43-230 and similar units. Though small, these units seem to be adequate for casual FM-style mobile work. Old police or taxicab speakers in good condition also can be used.

For the operator who likes to occasionally use his handie-talkie in the family buggy, Heath's HDP-1228 clip-on sun visor speaker is a good bet. The 7-oz. dual speaker has two large mounting fingers (similar to those used on visor mirrors) to hold the speaker onto the visor just above the driver's head. This method of mounting allows optimum positioning of the speaker to direct the sound downward where it's needed to overcome road noise. An eight-foot-long cord and mini-plug allow easy connection to the HT or any other mobile transceiver. (This item, manufactured by Superex Electronics Corp., may have been discontinued by Heath, as I haven't seen it advertised in recent catalogs.)

Just about any CB-type external speaker will yield adequate results. However, there is one new amateur unit on the market that warrants mention: the Kenwood SP-40. This is a compact, but high-quality, lightweight (.44-lb.) speaker having a power handling capability of 3 Watts with a frequency response of 400 to 5000 Hz. Although speaker size is only 57 mm, the little unit appears to be quite efficient and free of annoying resonances and vibrations that too frequently plague lesser CB counterparts. The speaker leg has a magnet so that it easily can be mounted on any magnetic substance. If the speaker is to be installed in a location where the magnet can't be used, mounting screws or double-faced adhesive tape also can be used. Somewhat on the expensive side (about $25), the unit nevertheless represents good value (I own two, one for each automobile). The speaker's aircraft-instrument styling makes it an especially attractive complement to any mobile installation.

Headphones for the Ham Shack

Loudspeakers are great for armchair-copy SSB work and for casual, FM-style operating. But there are a number of advantages in owning and using a good set of headphones as an adjunct to the trusty station speaker.

Many DX signals are too weak and QRM-obscured to be properly copied on a loudspeaker; a good set of phones will be of considerable value in increasing your ability to pull weak and near-buried signals out of the pack, particularly on CW. Room, household, and outside distractions also will be markedly reduced, allowing maximum concentration on the signal being copied. The overall effect of using headphones can be about equivalent to doubling received signal strength, when compared with straight loudspeaker listening. This may mean the difference between a solid DX contact and none at all.

A secondary, yet important, reason for using headphones is that the phones isolate the ham shack from the rest of the household, whose members may not appreciate the objectionable whistles, squawks, and other noises that are music to the ham's ears. This is especially important when practicing code, since Morse blasting forth at 750 Hz can have a very shrill and unnerving quality that readily penetrates walls, ceilings, and floors—not to mention *people!* Apartment and condo dwellers are well aware of how unpopular Morse can be with the neighbors.

I built a small FM rebroadcaster for cord-free headphone monitoring in my ham shack. The unit shown uses the 100-mW Ramsey FM module, which easily can be tuned to a clear spot on the FM band. Output of the station's TS-180S, FRG-7, or R-1000 is fed through the Autek Research QF-1 audio filter to the FM unit. A pair of lightweight "radio headphones" completes the installation.

Communications phone requirements. Many beginners start out by appropriating the closest set of stereo hi-fi phones for their rigs, with little thought of whether the unit can do the job. Most decent stereo phones can be used, but because they are designed for high-fidelity reproduction, their wide frequency response may elevate internal receiver hum and noise to an objectionable level; also, some lead-switching needs to be done to adapt them for monaural use.

Far better, and a more suitable investment for a lifetime amateur radio career, is a good pair of *communications*-type headphones. Such phones will boast a relatively narrow frequency response, high sensitivity, and easy physical adjustment. They also will be designed for comfortable wearing over extended periods, and the earmuffs will be effective in isolating the operator from distractions. Several manufacturers sell communications-type phones, including Telex, Superex, Radio Shack, and Amplivox. Major ham gear manufacturers such as Kenwood and Yaesu offer a selection of radio headphones designed to both physically and electronically match their equipment lines.

Several considerations emerge. Input impedance should match the output impedance of the receiver or transceiver's audio stage. In almost all solid-state amateur gear this is low impedance, in the 4-to-16-Ohm range; normally, 8-Ohm headphones should be obtained, though lower-impedance units will probably work nearly as well. Some older ham gear was designed for high-impedance phones, usually 1k to 5k Ohms, however; imped-

A good pair of headphones will last a lifetime of hamming. Though communications-type phones are usually recommended, high-quality stereo headphones are often preferred because they usually sport extra-soft, oversize cushions and padded, adjustable headbands. An adapter cord or plug would be required to convert a stereo phone such as this Radio Shack unit for monophonic use with your *receiver or transceiver. (Photo courtesy of Radio Shack)*

ance matching is more critical in such instances. Most military surplus headphones, often attractive because of their rugged construction and oversize earmuffs, are 500-to-600-Ohm units, though they are sometimes seen in higher- and lower-impedance versions.

Sitting in front of a ham rig for many hours at a stretch is fatiguing. Doing this while wearing an uncomfortable set of headphones, sporting a tight and close-fitting headband, is torturous. For reasons of retaining one's sanity and a pleasant disposition, it's critically important to purchase earphones having good earmuffs; the muffs keep the signal in and distractions out. Thick, but soft, flexible pads are what are required; they should be held fairly tightly against the head by the headband's pressure, though not so tightly as to be noticeably uncomfortable. One should be careful in purchasing used headphones, even if they're OK electrically, because old earmuffs eventually become shopworn and stiff, primarily due to their having been soaked in the operator's perspiration. Deterioration of the high-frequency response is the result, along with a reduced isolation ability. Overly large, heavy headphones should be avoided due to the discomfort caused by carrying their weight over an extended period.

Some features to look for include a coiled cord, individual headset volume controls, interchangeable or easily-replaceable earmuffs, type of headband construction (single, double, padded, etc.), and a means of adjusting the headband. These factors may be either pluses or minuses, depending on individual operator preferences.

I have found that buying headphones is one task that is best done in person, not by mail. It's important to try out the phones, if possible with the radio with which they will be used, both from the standpoint of equipment compatibility and operator comfort. All the printed specs in the world are useless if you can't comfortably wear the phones over a long timespan. If possible, borrow several different phones from friends and check out their suitability in your own station before making your choice.

Except for mobile work, where a *single* headphone may be worn in conjunction with a boom mike/headset combo, a *pair* of headphones is universally used. Since the human hearing system tends to cancel out noise which is applied equally to both ears, adding the second headset allows recognition of signals several dB lower in level than with a single headset. Also, most people do not have equal or symmetrically balanced hearing in both ears; dual phones tend to minimize this anomaly.

A few headphone operating tips should prove helpful:

1) Try using a pair of fitted earplugs under the headphones. Desired signals will come through the earplugs fairly well, while noise will be suppressed. Using earplugs is particularly effective when working on an extremely noisy band for a long stretch. You also may find fatigue is reduced.

2) Experiment with reversing the audio leads to one headphone. The human ear tries to cancel out noise which is presented in-phase to both ears; swapping the normally in-phase headsets can produce a substantial readability improvement while letting the signal of interest through with minimum impediment. If results are favorable, you may wish to install a switch to conveniently reverse phase for routine listening.

3) Learn to "ride gain" on your set's rf and af gain controls, avoiding "blasting," which will have the temporary but undesirable effect of desensitizing the ears. Generally, best CW copy is had by running with the af gain wide open (or nearly so) and working with the rf gain control, keeping levels low enough to avoid receiver and headset overloading. A good receiver agc system makes doing this a lot easier.

4) When operating on CW, carefully adjust the set's main tuning or beat frequency oscillator (bfo, if the set has one) to produce a strong yet pleasant audio tone. Don't opt for a too-low pitch; around 750 Hz is usually about right, give or take 100 Hz, or so.

5) If you're an inveterate SSB contester, consider the use of a boom mike/headset combo. This device replaces, or supplements, the transceiver's existing mike and speaker. The boom is attached to the back of one of the headphones and curves around the operator's cheek, thereby positioning the mike directly in front of the mouth for close-talking and essentially hands-free operating. A press-to-talk (PTT) switch is part of the cord itself, though most boom-mike assemblies can be "hot-wired" and a foot-switch used for PTT switching for true hands-off operation. Use a double-headset type for fixed-station operation and ensure that mike and headphone impedances are right for the transceiver or receiver/transmitter pair with which the combo is to be used. Avoid cheap CB-type boom assemblies like the plague!

6) If you want to try cord-free headphone operation, purchase a pair of lightweight, cordless FM radio headphones—the kind that has a built-in FM or AM/FM radio inside the headphone

itself—and feed your rig's output to a small wireless FM broadcaster module. Doing this allows true cord-free flexibility in the ham shack by doing away with clumsy, entangling headphone cords. The setup also has the benefit of allowing one to monitor band or net activity anyplace in the home or yard by tuning in the rebroadcaster on any standard FM receiver. Ramsey Electronics, 2575 Baird Rd., Penfield NY 14526, sells a simple, 300-foot-range kit for $3.95. Food for thought!

Using stereo phones. We have cautioned against using stereo hi-fi headphones in the ham shack, regardless of their quality and comfortability. Headphones with extremely wide frequency response characteristics simply reproduce additional interference, detracting from desired signals. Nevertheless, many hams will wish to use a pair of existing stereo phones for reasons of economy or personal preference. Hands-on experimentation will reveal if the pair will, in fact, be suitable for use.

Unfortunately, you can't just plug a set of stereo phones into your ham rig. Almost all such headphones use a so-called standard three-conductor (including ground) plug, one circuit being used for each channel. Most amateur equipment uses a two-circuit (including ground) jack for use with *monaural* communications headphones. This fact requires replacement of the headphone's 3-circuit plug with a single-circuit plug and the paralleling of the two separate leads so that the receiver's output will be fed to both headset units. Alternately, the stereo headphone's plug can be left intact and an adapter purchased or fabricated to convert the stereo-configured cord to monaural use. Using an adapter has the advantage of allowing the headset to be used as a stereo unit whenever desired, without making further wiring changes.

If you *do* purchase a set of stereo headphones to use with your ham rig, consider a suitable pair that has an internal "stereo-mono" switch. This feature alleviates the need for an adapter plug. I own a Calrad 15-135 headset that does a creditable job both in the ham shack and with a small stereo set, and it boasts individual earphone volume controls, a coiled cord, and comfortable muffs.

I've indicated that the stereo headphones' wide frequency response may be annoying when used with ham gear. This may be particularly aggravating if you try to use a pair of stereo phones in tandem with an active audio filter, since the filter may emphasize residual ac hum and noise present in the receiver or transceiver's audio output. You can minimize this problem by adding a 50- to 150-Ohm, 1/2-Watt resistor in series with the headphone lead to cut down their low-frequency response and overall sensitivity. The exact value to use must be determined by experiment.

Using a high-quality pair of communications-type headphones has several advantages. Switching from speaker to headphones can materially improve the readability of received signals and keep distracting room noise out. Lightweight units with soft cushions that are peaked for communications-range audio are best. Low-impedance models, such as the Yaesu headset shown here, are suitable for most modern solid-state receivers and transceivers. (Photo courtesy of Yaesu Electronics Corporation)

Tape Recorders

Though by no means necessary accessories, tape recorders represent often overlooked but very useful station adjuncts. There are countless practical uses for recorders, many of which are suitable for the ham shack. In fact, many amateurs wouldn't be without one any more than they would be sans mike or key.

Ham shack applications. Small recorders have a wide range of applications in the ham shack that is limited primarily by the individual operator's ingenuity and imagination. Recorders can be used for such diverse purposes as recording DX and other important contacts, verifying transmitted audio quality, recording messages and traffic, code practice, making short CQ and other transmission tapes, signal reporting, and SSTV signal origination, to name but a few popular uses. Let's look at some of these:

1) *Taping contacts.* This represents the most common, obvious use of the recorder. The machine is simply connected to the receiver's output jack, either through a Y-plug across the speaker or, in some sets, to an auxiliary tape-output jack. The tapes made can serve as documentation for exceptionally rare QSOs and as a logging aid in fast-paced DXing and contest work. (In the latter application, a reference time is recorded at the beginning of the tape so that log entry times can be conveniently determined.)

2) *Signal reporting.* Another common use is to provide "live" signal reporting to others. Most hams are genuinely surprised to learn how they really sound over the air, particularly at a far-distant location. They are usually highly appreciative of an offer to play back their signal to them as much more meaningful than a simple readability-and-strength report. If you make a practice of providing on-the-air playback, keep the engineering practice up to snuff: hardwire the connections (no mikes placed up against the set's speaker), and ensure that your wiring arrangements permit professional switching between mike and recorder. Random bleeps and fast-forward monkeychatter are not well received over the air. A recorder with an accurate tape counter is a near-must.

3) *Transmitted signal quality checking.* A good

The uses for a tape recorder in the ham shack are legion: taping QSOs, CQs, code practice, traffic for relay, etc. The recorder is probably of most use to the SSTV enthusiast in editing programs and recording QSOs—though recorders for SSTV work must be a cut above the average home-type cassette. The Sony C-104, shown above, is ideal for these purposes.

way to find out how *your own* signals sound is by using your recorder to tape them. You will need an auxiliary receiver for the purpose, one whose antenna can be disconnected or which has an attenuator to eliminate front-end overload by your own signal. You can record your actual on-the-air transmissions and QSOs, of course, but if you do any extensive "hello . . . testing" for the specific purpose of making a tape check, be sure to use a *dummy load* rather than radiating a signal.

4) *Code practice.* You easily can make custom code-practice tapes using your key, keyer, audio oscillator, and/or keying monitor in your transceiver or transmitter to feed the recorder's input. If you have an open-reel machine, you can in most cases vary the recorder's speed in a 2:1 ratio, that is from 1-7/8 to 3-3/4 ips, or from 3-3/4 to 7 ips. This capability allows code tapes recorded for the level of instruction desired (audio pitch will change, naturally). The recorder also can be used to tape on-the-air code practice sessions regularly broadcast by W1AW, the ARRL station at Newington, Connecticut, for later playback and practice.

5) *Traffic handling.* Using a recorder as a running backup in traffic handling is a good idea practiced by many experienced brasspounders. If you handle a great deal of traffic, you know that a telephone call or other unwanted interruption can make you miss part of a message or cause you to hold up your net while you get a "fill." Using the recorder, you can effectively tape your own fills.

6) *Taping CQs and other transmissions.* There is nothing wrong with prerecording phone CQs, if the practice isn't overdone and technical quality is maintained. For the most part, tape-recorded CQs are not necessary, and those using them often sound a bit silly. However, for contesting and some DX work, there *are* time-saving possibilities. A related application lies in making extended antenna adjustments and TVI checking. Since radiating an unmodulated carrier is illegal (except for short periods), you may want to prerecord a signal which can be played through your transmitter again and again. For both these applications, special continuous-loop tapes are available; these come in various lengths to fit the desired transmission message length. Again, the watchword is moderation—don't overdo a good thing!

7) *SSTV recording and playback.* The tape recorder is a "must" for the SSTVer, who finds a wide range of specialized applications. These include generation of gray scale, test pattern, and other reference signals; immediate playback of the other fellow's over-the-air picture; and building a library of interesting programs from two-way contacts. By far the most important use is in prerecording one's own "programs" for later broadcast. This allows for careful preparation and capturing of artwork and photography, tape editing, and review. The judicious use of a simple tape machine has enabled many SSTVers to produce very smooth, interesting and professional-quality program material that's a pleasure to watch.

8) *Computer interface.* Small cassette recorders provide the basic means of programming home-type microcomputers. If you're equipped with a microcomputer with an electronic RTTY and/or CW interface, the recorder provides the means to set up the computer for RTTY or Morse transmission and reception, and it also serves other ancillary functions. For example, in the author's Macrotronics M-650/PET 2001 system, the recorder is used to prerecord messages for later transmission and to record received messages. So-called "brag tapes" and artwork can be stored on the tapes and exchanged with others.

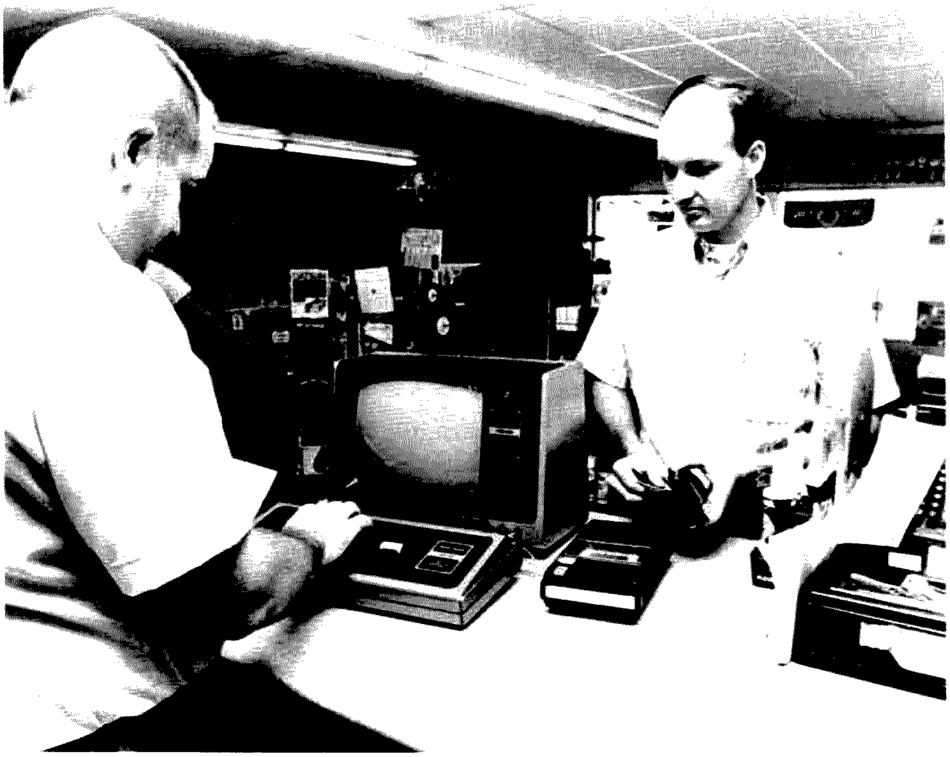
Besides these specific uses, it's often handy to use a tape recorder to verbally document equipment settings and alterations, meter readings, and test results. The work being done is described as *you're doing it,* with the recorder doing the "writing." Subsequent playback of the tape, and written transcription to a notebook or log if required, may be helpful in interpreting and analyzing results and in learning from past mistakes.

Technical considerations. Authentic high-fidelity sound reproduction isn't a necessity in a ham shack recorder, though a few requirements *do* exist. The recorder should be of reasonably good quality (not a child's toy, to be sure), feature low distortion, have an auxiliary input for direct connection to the receiver's speaker, and include a recording level meter and tape counter. A "pause" or "edit" control is also a desirable feature. Requirements are tighter if the unit is going to be used to record SSTV signals or interface with a microcom-

puter; in these cases, a top-quality recorder having low wow and flutter should be selected. Other desirable, though not absolutely essential, features include a monitoring and/or auxiliary speaker jack, public address (PA) mode, automatic shutoff or track reverse, and fast forward and reverse capability. A monophonic unit is fine; there is little advantage in using a stereo unit.

Several tape formats are suitable: eight-track, reel-to-reel, and cassette. The eight-track recorder, operating at 3-3/4 ips, uses 1/4-inch tape in a track configuration that allows eight mono channels or four stereo channels to be recorded. Since the cartridge is actually an endless tape loop, it will run continuously if left to play out. Very short length cartridges are available, making this format excellent for phone CQs and even short SSTV "takes." The eight-track format does have its drawbacks, however, in terms of less-than-optimum audio quality, a tendency for tapes to become jammed internally, and the objectionable "click" and momentary loss of audio when tracks are switched.

The open-reel recorder is hard to beat for quality. Its distortion figures and frequency response are best among the three formats. Various combinations of reel size, tape length, speed, and available accessories add up to maximum versatility and flexibility. Recorder mechanical design is relatively straightforward (when compared with eight-track and cassette models), and maintenance is less difficult and costly to perform. However, the open-reel recorder—at least a good one—is expensive, and tapes are not as convenient to use as in the other two formats, manual tape threading being required on most models.



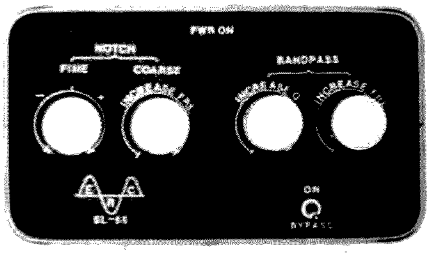
Tape recorders find many useful applications in the ham shack. A growing use is connection with digital microcomputers, where they are used for loading and recording of cassette programs and data. Radioteletype (RTTY) and Morse code interfaces are available from several sources for popular home computers such as the Apple, PET, and TRS-80, shown here. In addition to the basic program-loading function, the recorder can be used to digitally record on-the-air transmissions and to prerecord outgoing messages (including "brag tapes") for later broadcast. (Photo courtesy of Radio Shack)

The cassette machine is the most popular for ham shack use today, for reasons of relatively low cost, operating convenience, and steadily increasing quality. The cost of a small cassette unit is certainly not prohibitive, with usable machines available for as little as $25 to $30. Even high-quality monophonic portables come in at less than $100. The ever-increasing popularity of cassette machines is due in large measure to the ease with which tapes can be selected, loaded, recorded, and removed from the recorder, features that are very attractive for station use. Tapes in practically any length can be obtained for recording periods up to 120 minutes or more, using the standard cassette speed of 1-7/8 ips. The biggest disadvantages are that cassette editing isn't practical, the low tape speed mitigates against top quality recording, and accurate cueing is difficult. Most portable machines have an audio response that is entirely adequate for ham-band and shortwave signal reproduction, however.

An SSTVer, I opted for the Superscope C-104, a very high quality mono portable that includes such desirable features as cueing capability, pause control, nicad operation, built-in condenser mike, PA function, and variable tape speed. The front-panel controls and meter make it especially convenient for stacking above the station speaker or receiver—you don't have to look down on the recorder to operate it, as one must do with most small portables.

Standard front-loading stereo decks offer excellent potential though probably represent an overkill in quality. A stereo deck or recorder obtained at a reasonable price could likely be put to good use in the shack, though the second channel would be wasted. The micro-cassette recorders also offer good possibilities. Many of these units are quite small, can be operated vertically, and thus can be sandwiched in between equipment units on the operating console.

In using a recorder in your station, you may experience trouble with rf pickup, making it unusable when transmitting. The problem can be acute in solid-state units and comes about because of audio rectification of your signal by the set's amplifier stages.



ERC SL-55 audio filter is said to improve SSB and CW reception under severe conditions. The unit contains three separate filters: independent and continuously-adjustable bandpass filters as well as a fixed low-pass filter that can be cascaded with the others. The unit generates 1 Watt of audio and has an input/output impedance of 8 Ohms. (Photo courtesy of Electronic Research Corporation of Virgina)

Simple RFI-preventive measures, such as installing an rf choke and bypass capacitor in the recorder's mike and/or auxiliary input leads and bypassing the audio output leads and ac line, will often do the trick, unless you have a very poor station ground or are using a voltage-fed antenna that produces an inordinate amount of stray rf in the shack.

Various patch cords, connectors, switches, and jumpers may be required to conveniently use the recorder with your equipment; these only can be determined after deciding which functions the recorder is to fill. Using shielded cable for all audio connections should go a long way in reducing rf feedback, noise, and hum pickup.

Audio Filters

The congestion on the amateur bands has placed a premium on receiver/transceiver selectivity. Simple fixed-bandwidth i-f crystal filters were good enough for the 40s and 50s, but not good enough to adequately handle present-day QRM conditions. Densely-packed and overlapping SSB stations, closely-spaced CW signals, and RTTY reception through potentially obliterating heterodynes demand complex i-f filters or other means of achieving a high level of receiver selectivity.

Many upper-end receivers of 50s and 60s vintage contained special i-f circuitry using double-conversion techniques to allow the operator to peak the desired signal or null out an offending one. At the time, the best way to improve selectivity on inexpensive receivers was to add an outboard i-f-stage "Q-multiplier," which enabled the operator to either peak a desired signal or null out an offending one by manipulating one of several panel controls. The Q-multiplier (the best-known being Heath's QF-1) was capable of doing a good job, but some practice was required in using it. It went out of favor as the once-standard 455 kHz i-f frequency was largely abandoned for higher and lower i-f frequencies in double-conversion configurations. The transition from tube to solid-state designs also had a lot to do with the Q-multiplier's demise.

The basic means of attaining the desired amount of receiver selectivity today is by means of an i-f stage crystal or mechanical filter. Most high-quality transceivers use a filter with a steep shape factor to reduce out-of-passband signals and noise; the same filter is usually used on transmit. If your receiver or transceiver has provisions for optional i-f filters for reduced-bandwidth SSB and CW reception, it's a wise investment to obtain them—especially the CW filter. Some manufacturers, such as Kenwood, also offer provision for adding a second (dual) SSB filter assembly to further sharpen the response curve and improve the i-f stage's signal-to-noise (S/N) ratio. Addition of the second filter also has a beneficial effect on transmit, allowing a greater degree of speech compression to be used without a significant increase in sideband splatter and resultant bandwidth.

While most i-f filter arrangements don't offer true single-signal reception, those receivers and transceivers that have provision for shifting the center frequency of the i-f crystal filter (variously known as i-f-shift or passband tuning, depending on the manufacturer) offer additional possibilities for minimizing QRM and further improving overall S/N ratio.

Even in those sets having adequate i-f filtering, the addition of an audio filter can enhance performance. The audio filter acts in two ways: 1) It cuts down on the wideband noise generated by the set's i-f chain, preventing amplification by the set's audio stages, and 2) it further narrows the receiver's overall response curve, often allowing true single-signal reception. Both characteristics significantly aid reception when the QRM level is up and when working under weak-signal conditions.

Passive audio filters. A fixed-tuned, passive (non-amplifying) audio filter can do a great deal to improve the selectivity of a receiver, especially one without an i-f filter; in some inexpensive sets, an audio-stage filter is the *primary* selectivity-determining device. Many hams found that war surplus radio range filters inserted in their radios' headphones lead did a good job in separating closely-spaced CW signals, though the filter frequency of most of these units was a bit high-pitched to suit many and receiver tuning and stability became critical when using very narrow bandpass filters.

More sophisticated designs have been developed over the years, using large fixed-value inductors to achieve the desired degree of selectivity at audio frequencies. The radio handbooks are full of good passive filter designs, especially for use on CW. A particularly good one is the six-element L/C CW bandpass filter designed by Ed Wetherhold W3NQN. It appears on page 8-27 of the 1980 ARRL *Radio Amateur's Handbook*. Other W3NQN designs appear in the December, 1980, *QST*. Another practical filter approach is that of Del Crowell K6RIL that appeared in the March, 1968, *CQ Magazine* in his article, "Adding CW Selectivity for Transceivers."

Passive filters are brute-force devices, however; they are lossy—very noticeable if one wants to drive a loudspeaker. Though easy to build, the passive devices rely on large, cumbersome and often hard-to-find toroidal inductors. Also, there is no flexibility in setting the center frequency and bandpass curve or changing these characteristics during operation. A far more satisfactory approach lies in the use of the *active* audio filter.

Active audio filters. The active, or tuned, amplifying audio filter uses RC networks in conjunction with solid-state amplifiers to *synthesize* the inductor characteristics. The simulated inductance is resonated with a capacitor to produce a tuned-filter effect. What makes this kind of filter so popular with hams is that the filter can be constructed with variable Q and variable center and cutoff frequencies; this allows convenient front-panel control of the filter's operating characteristics that the operator can precisely tailor to suit his mode of operation, personal preferences, and band conditions.

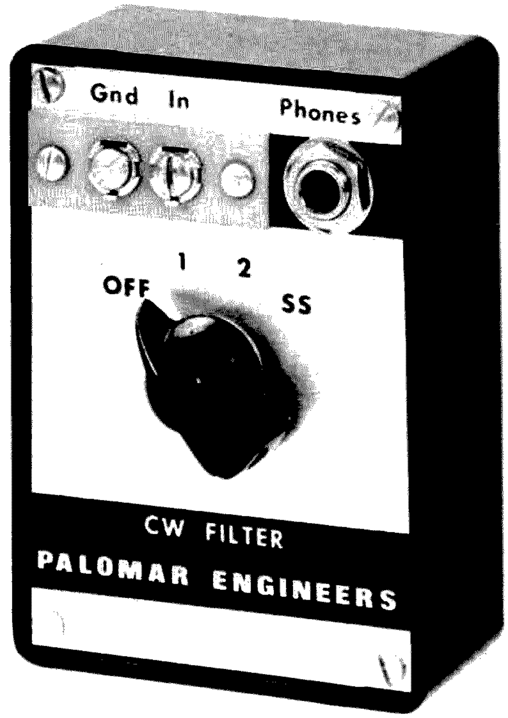
The current spate of solid-state active filter designs are descendants of the classic National Radio "Select-o-Ject" audio filter that was immensely popular about 30 years ago. This tube-type accessory was a handy, quick-and-dirty supplement to a receiver having little real selectivity. Present-day active filters offer a number of specialized features that make them of great interest to both CW and SSB operators.

An active audio filter can be built from one of the many designs regularly featured in the ham magazines; several are in the *Handbook*. At least a dozen firms sell these very cost-effective QRM-suppressors that allow even a modest receiver or transceiver to come to life in the selectivity department, particularly on CW. Manufacturers include Autek Research, Kantronics, M&M Electronics, Datong, Electronic Research Corp. of America, Palomar Engineers, MFJ Enterprises, and several others.

Typical handbook and commercial designs enable operation on either CW or SSB, though a few less-expensive filters are for CW-only or SSB-only use. The majority are self-contained and include their own power supply or draw power from the receiver or transceiver's accessory jack. Most are connected to the set's audio output jack and contain a small internal audio power amp to directly drive a speaker or headphones. The filters enable the operator to adjust selectivity from a few Hz, for razor-sharp CW performance, up to a completely flat response. Many have separate high-pass and low-pass operating modes, especially useful on SSB; others have a deep notch feature that is used to null out an interfering signal or heterodyne without degrading the desired signal. A few sophisticated models allow dual (simultaneous) notching and filtering; at least one model contains a built-in noise limiter.

Using the active filter on SSB is a gratifying experience, especially if in conjunction with a modest set—though top-of-the-line models will benefit as well. By proper control-knob manipulation, it's possible to dramatically improve signal readability under conditions of QRM, static, splatter, and the like—reducing operator fatigue and making listening a great deal more pleasant. SWLs, 10-meter AMers, and CB operators should be interested in the capabilities of the active audio filter, too. Selectivity on the crowded AM shortwave and standard broadcast bands is considerably improved, and stations just a few kHz apart can be separated with little cross-channel interference.

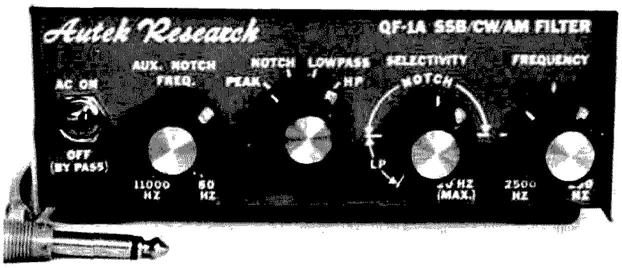
The real thrill comes when using one of these filters on CW. Used in conjunction with a set's existing CW i-f filter, results can be truly impressive. With the active filter, the desired signal can be peaked with



Palomar Engineers' CW filter connects between the receiver and a set of stereo headphones. There are actually two filters, a narrowband one with an 80-Hz bandwidth (centered at 800 Hz) and a wideband one that cuts out hum and high frequency interference but passes most of the receiver audio signal. The narrowband signal goes to one ear, the wideband to the other, giving simulated-stereo reception. The effect is to offer a signal "mix" that is an improvement over either filter alone: The off-frequency signals appear in one headphone, the desired signal in both. The operator's mind concentrates on the desired signal and rejects the interference. Long operating periods are said to be less fatiguing using such an arrangement. (Photo courtesy of Palomar Engineers)

an effective bandwidth measured in *tens of cycles,* even in the presence of close-by strong signals that have managed to bull their way through the radio's i-f strip. Even with a sharp i-f CW filter installed, it's possible to actually *tune through* the set's i-f passband with the audio filter and discover several individual CW signals that can be brought up to solid-copy levels that were unreadable or scarcely detectable without the filter. Of course, there is a limit to the degree of selectivity one can crank in; with too much selectivity, filter "ringing" becomes objectionable. Also, using the notch feature, very pronounced unwanted signal rejection (sometimes 70 dB or more) can be attained by proper control manipulation.

Space-age filtering. A couple of takeoffs on active filtering techniques have surfaced in recent years. One is the concept of simulated-stereo reception,



An "outboard" active audio filter can yield surprising performance benefits in conjunction with even the most expensive receiving equipment. Assuming such a filter is used with a receiver or transceiver having reasonably good i-f selectivity with good "skirts," weak and QRM-plagued SSB signals can be made to "jump out of the noise" in many cases. And in the sharpest modes, several CW signals may be copied within the set's passband and tuned in separately. Autek filter shown here is based on a design pioneered by the firm in 1972. (Photo courtesy of Autek Research)

described by Max Blumer WA1MKP in his October, 1974, *Ham Radio* article, "Enhancing CW Reception Through a Simulated Stereo Technique." In this approach, an active filter is used. Unprocessed receiver audio is fed to one ear, and filtered (processed) audio is fed to the other ear. This technique allows you to read slightly off-frequency CW stations while simultaneously hearing the desired signal, in the clear, in the other ear. The brain does the ultimate filtering—it "hears" all the signals, but the processed signal stands out solidly, with the others mentally rejected. The bottom line is that the filter allows greatly improved reception of the desired signal, but also allows you to hear off-frequency replies to your CQs; it's also easier to scan the band using the simulated-stereo technique. A stereo headphone is required for this type of filter, which is offered commercially by both Palomar Engineers and MFJ.

Especially interesting is the automatic-tracking audio filter offered by Datong. In addition to some impressive narrowband tuning capabilities, the FL-1 frequency-agile audio filter features fast automatic suppression of interfering heterodynes in the range of 280 to 3000 Hz by means of its search-lock-and-track notch filter. The tracking notch can be left in the circuit with no audible effect until a whistle appears; the circuit then goes after it and will suppress it within 1 second.

How does it work? Two phase-sensitive detectors control signals used for automatic tuning. One produces a voltage proportional to the degree of mistuning, and the other produces a logic level indicating the presence of a signal within the filter passband. In the absence of such a signal, the integrator becomes a sweep generator. But when a signal is detected, the sweep stops, the unit's lock lamp illuminates, and the integrator becomes part of an automatic frequency control (afc) negative feedback loop. The filter then remains locked to the "captured" signal and will track it, if required, throughout the filter's range of 280 to 3000 Hz. This capability allows the routine use of an extremely narrow (20 Hz) notch which does not noticeably affect received signals and which would be nearly impossible to manually tune and maintain in tune. Of interest to CW ops, an attenuated afc voltage is also used in the manual tuning mode to allow the filter to automatically track *drifting* CW signals over a 100-Hz range!

Whether you opt for a simple or complex filter, you'll likely be glad you made the investment. Dollar-for-dollar, an audio filter is one of the best accessory aids you can buy for your receiver or transceiver.

Wrap-Up

In this article, we have discussed a wide range of basic, yet important, phone-jack accessories: headphones, speakers, recorders, and filters, with a view to obtaining maximum usefulness from dollars spent on station equipment. For most hams, this group of reception accessories probably represents the most important initial accessory investment. For this reason, and for space limitations, we've not discussed exotica which might otherwise fit the article's "phone-jack" scope, such as SSTV viewers, RTTY/Morse decoders, monitorscopes, phone patches, and the like. We'll reserve discussion on these "second-level" accessories until a later time.

In the final analysis, *you* must decide which, if any, accessories to build or buy. Hopefully, the criteria, suggestions, and observations provided in this article will help make your decisions both logical and wise. ■

OSCAR ORBITS

- The Amsat Software Exchange has recently been formed and is now accepting orders. The first program being made available is the orbital prediction program written by Dr. Tom Clark W1IWI. It is available for most popular machine environments, with other versions being developed. Presently available are TRS-80 disk and cassette versions, Apple/II diskette, Microsoft BASIC, and PL/I-80. This program will accommodate the elliptical orbit tracking required for the Phase III satellites. For complete information on versions available as well as new additions and ordering information, send an SASE to: AMSAT Software Exchange, Box 338, Ashmore IL 61912.
- The early months of amateur radio's newest satellite, UoSAT-OSCAR 9, were full of developmental work. The Surrey, England-based ground crew concentrated on generating and relaying to the bird a computer program that will allow the craft to stabilize itself via on-board torquing coils and a gravity gradient boom. Once this is accomplished, the experimental part of the mission will commence.
- AMSAT, the people who organize ham radio's space communications program, received a "royal boost" from JY1, Jordan's King Hussein. While visiting the US in early November, the King expressed his support to AMSAT President Tom Clark W3IWI.
- Although the AMSAT financial picture has been brightened by several large donations, there is still a need for grass-roots support by the entire ham population. You can find out more about AMSAT by writing to: The Radio Amateur Satellite Corporation, PO Box 27, Washington DC 20044.

Information for this column comes from the *AMSAT Satellite Report*.

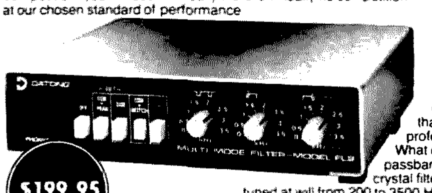
'DATONG'
INCREDIBLE PRODUCTS–REALISTIC PRICES!

WHAT IS AN AUDIO FILTER?
Why buy a Datong audio filter when you can get other audio filters for half the price?
To answer this you first need to remember that the title "audio filter" can mean anything even down to a couple of 741's and a handful of parts. Only by comparing like with like can you make an informed decision. This means comparing features, performance and quality. If you send for our free data sheets and compare our products with the competition you will see that really there is virtually no competition at our chosen standard of performance.

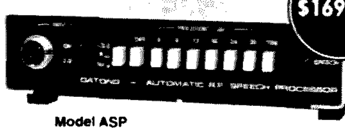
$149.95
Model FL1



$199.95
Model FL2

What other audio filter can tune into heterodyne interference like tune-up whistles and notch them out, **automatically** like our Model FL1? Yet Model FL1 is also such a good CW filter that it is widely used by professional traffic handlers.
What other audio filter has passband edges sharper than SSB crystal filters and yet which can be tuned at will from 200 to 3500 Hz? To pull off this trick our Model FL2 uses no less than 32 op amps plus state-of-the-art pulse width modulation techniques. Two 5-pole elliptic filters and a 2-pole peak or notch filter in one box, all independently tuneable add up to a lot more filtering capability for SSB, RTTY, CW than you will find in any other "audio filter" that we know of.
To answer our question then, an "audio filter" can be almost anything. On the other hand, the phrase "Datong Audio Filter" is a lot more precise. It stands for state-of-the-art filtering backed by extra capability, extra thorough design and extra quality. If you need confirmation, ask a user!

ADDITIONAL PRODUCTS
Just as our two audio filters set new standards for innovation and invention, our other products demand serious consideration for the same reasons. Each offers a unique combination of features which you will not find anywhere else. We don't have space here for the full story but our data sheets are available free on request. Some brief details follow.



$169.95
Model ASP

Model ASP: The "smart" rf speech processor
The automatic circuitry in Model ASP senses your voice level and reacts accordingly to always maintain the degree of true rf clipping selected (in decibels) by the panel push-buttons. Novel circuitry avoids "hang-ups" by discriminating against noise spikes and non-speech inputs. Make no mistake. Model ASP connects in the microphone line yet gives true rf clipping for speech enhancement with minimum distortion.

Model D70: The go-anywhere Morse Code Tutor
Extracting sixty hours of code practice from a low cost nine volt battery, Model D70 gives you freedom to practice anywhere to suit your timetable and lifestyle. Model D70's variable extra delay between letters is the key to painless progress in code reception. Simply set the "SPEED" control to, say, 12 *words per minute and reduce the extra "DELAY" as your ability improves.*

$99.95
Model D70

Model PC1: Adds full receive coverage from 50kHz to 30 MHz to any 2 metre all mode rig. Designed for high performance. Model PC1 features LSI synthesisers for 1 MHz steps, parametric mixer for extra good dynamic range, automatic selection of rf preselector filters. Same case style as PL 2 and ASP. Price $259.95

Model DC 144/28: High dynamic range 2 metre converter
Especially suitable for use with Model PC1 to add 50 kHz to 30 MHz coverage to 28-29 MHz receiver. Uses Schottky mixer. PTH board 5th overtone crystal oscillator. Price $74.95
Model VLF: Crystal controlled converter adds 10 kHz to 500 kHz reception to 28.0 to 28.5 MHz receiver. Price $54.95

A Dish Antenna Anyone Can Build

—no hyperbole, just a parabola

Michael Brown W8DJY
6297 Brown Run Road
Middletown OH 45042

Are you contemplating the challenge of operating on the amateur microwave bands? What about getting in on the excitement of receiving satellite TV signals? These and similiar projects usually require a dish-style antenna. You could buy one or, better yet, you can build one. This article will tell you how.

I wanted to put a signal on the 1296-MHz band. To do the job right, I needed a dish antenna. I took the plunge at a hamfest, buying a surplus military job made of spun aluminum, about 6 feet in diameter. It was one of those good deals you can't pass up.

Now my "good deal" sits in the corner collecting dust, waiting to be sold at the next hamfest. I managed to get a signal on 1296 using a dish two meters in diameter that I built myself. The design is one which uses easily-obtained materials and has a total cost of less than $100. Best of all, it need not be a long, involved project. In fact, you can build a dish like mine in a single weekend.

Photos by Tim Daniel N8RK

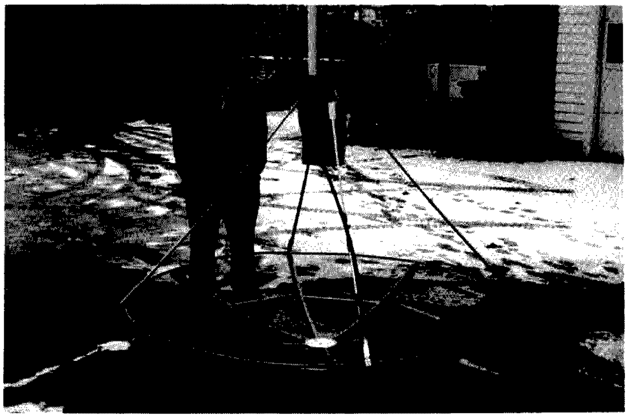

Photo A. The finished dish is light enough to be moved easily; the author stores his away each winter.

Some Theory

Before we jump into the details of construction, it would be a good idea to look at the basics of dish design. The dish, resembling an oversized child's snow saucer, is a paraboloid. Its unique geometric properties cause it to collect a beamwidth of energy from a distant source and reflect it to a central point known as the focal point, or focus. Similarly, a signal radiated towards the dish from the focus will be effectively radiated by the antenna.

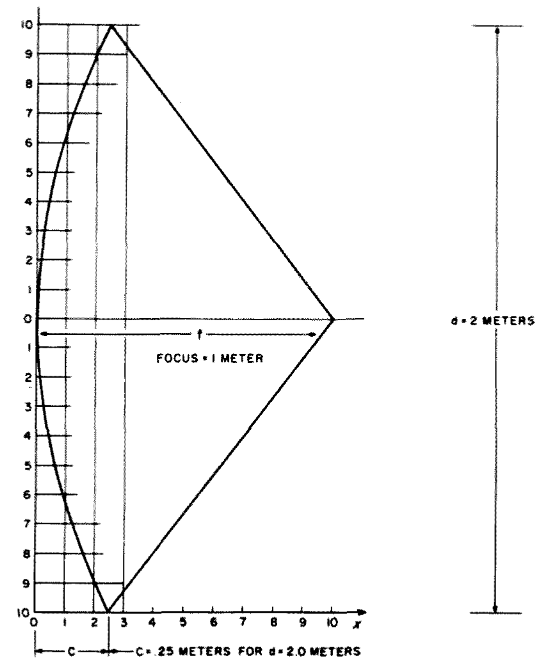
The important dimensions of a paraboloid are shown in Fig. 1. The reason my "good deal" dish turned out to be a piece of junk was that the relationship between the focal point and the diameter was all wrong.

Known as the f/d ratio, this relationship is very important when it comes time to feed the dish. Experience shows that dishes with f/d ratios of 0.5 and greater can be fed easily with a horn-style array. (My commercial dish's f/d ratio was about 0.25 and was difficult to feed.)

The diameter (d) is important in determining how much gain the antenna will have. Obviously, a dish 6 feet in diameter will collect more signal than a 3-foot dish. Each time you double the diameter, the gain increases by a factor of four (6 dB). The actual gain of a dish depends on its efficiency and the frequency it is used on. Assuming a reasonable efficiency of 50%, a 2-meter dish should have about 25 dB of gain over a dipole source at 1296 MHz. The 3-dB beamwidth will be about 8 degrees. Fig. 2 shows these relationships.

Once you have chosen the desired diameter, you'll know where the focal point should be to achieve an f/d ratio of about 0.5. In the case of a 2-meter dish, f will be at one meter.

The exact curvature needed to obtain a paraboloid with the desired focus and diameter can be found using the equation $y^2 = 4fx$. By calculating a number of points for x and y, you'll have an accurate plot of the shape required. Let's try an example for a dish with the focus at one meter: The x value corresponding to the y point of 0.5 is found by solving the equation $0.5^2 = 4(1)x$. A little algebra yields: $x = 0.5^2/[4(1)]$.



$$y^2 = 4fx$$

y = 1, x = .25
y = .9, x = .2025,
y = .8, x = .16,
y = .7, x = .1225
y = .6, x = .09

y = .5, x = .0625
y = .4, x = .04
y = .3, x = .0225
y = .2, x = .01
y = .1, x = .0025

Fig. 1. Dish dimensions. Width (c) is found by solving: $f = d^2/16c$.

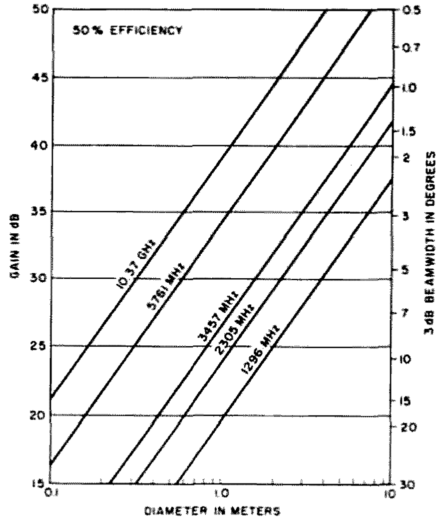


Fig. 2. Dish diameter/gain relationship.

Punching the calculator keys, we come up with the answer x = 0.625 meters. Fig. 1 also shows that the total width of the dish, c, is found with the equation $f = d^2/16c$.

That's all there is to designing the reflective part of the dish. Now let's look at how to build it. For starters, you should be prepared to work with metric measurements of length. I found that the use of meters and centimeters helps to ensure accurate results. For noncritical measurements, we'll refer to English units.

Once you have a set of x and y values, it is time to fabricate a surface that accurately depicts them. Any irregularities will impair the antenna's gain. At 1296 MHz, deviations of up to 1.5 cm are tolerable. As the frequency increases, this tolerance decreases. Using care, this dish can be built with deviations of less than 0.5 cm.

Making the Ribs

The structural elements that give the dish its strength and special shape are eight wooden ribs. I made mine from scrap 3/4-inch white pine. Each rib was cut from a 40″ × 14″ piece. Any available substitute should work, provided that it is reasonably light and can be cut to the needed shape.

Carefully draw a center line lengthwise, 5.8 cm from one edge of the board, as shown in Fig. 3. Work from this line to lay out a parabola, using the points generated by the $y^2 = 4fx$ equation. The more points you use, the more accurate your paraboloid will be. Carefully draw a line to connect the points on the inner surface. The outer surface should have a shape like the one shown. The lower flat edge will be at the center of the dish, while the upper end will be at the edge, fastened to a ring of aluminum tubing.

After checking the layout, the eight ribs can be rough-cut to about 0.2-cm accuracy using a band or saber saw. Final trimming should be done by sanding. Be sure to keep the flat edge parallel to the center line.

The ribs are all joined at the dish's center by a 3/4-inch-thick plywood mounting plate like the one shown in Fig. 4. Ribs A and B are mounted first, using 1-1/2-inch wood screws. All the other ribs must be shortened to obtain equal inside diameters. Ribs C and D have 3/8″ removed from the inside end. Ribs E, F, G, and H are shortened 3/8″ and mitered with two 45° angles as shown in Fig. 4(a).

Finally, all the remaining ribs are fastened to the mounting plate, first with glue and then with wood screws.

To add strength to the dish's outer edge, I encircled it with 1/2-inch aluminum tubing. Four six-foot lengths were used. To bend the tubing into a circle, one end is plugged, then the tube is filled with sand and carefully bent into shape. This was easier to accomplish than I thought it would be. An undersized piece of tubing is used for coupling between the sec-

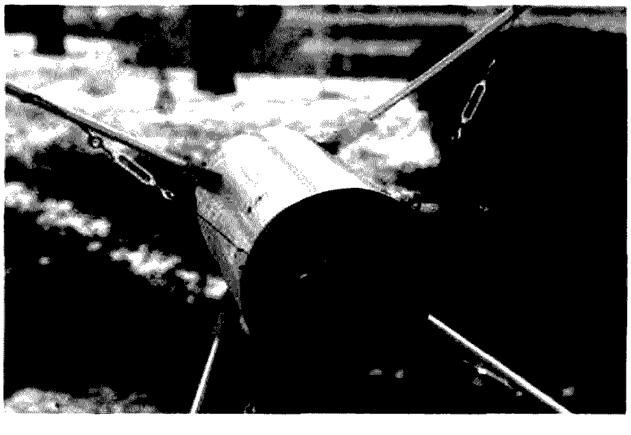

Photo B. A feedhorn can be easily constructed. The pickup is a simple, monopole element.

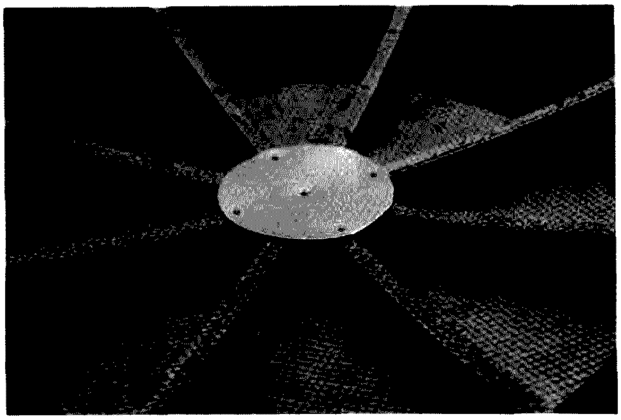

Photo C. A circular plate holds the reflective screening in place at the dish's center.

tions. The shaped lengths are fastened to the dish perimeter with 5-cent conduit clamps as shown in Fig. 4(b). Since the ribs give the dish its shape, getting the outside circle perfect is not necessary.

Covering the Frame

The next step is to cover your frame with a reflective surface. I used 1/4-inch hardware cloth because it was cheap and available. To make the job easier, I cut the cloth into eight slightly oversized triangles. Staple a triangle between two adjoining ribs and then trim the excess outer edge to size. Next, tie-wrap the perimeter to the aluminum tubing using nylon cord with cable-wrapping technique. Be sure to wear gloves when working with the hardware cloth.

Once all the screen is in place, eight flathead screws are used to hold it on each rib. (The staples are no longer needed and can be removed.) Since eight layers of hardware cloth overlap at the center, they must be trimmed and then securely fastened beneath a seven-inch diameter disc.

At this stage, all the essential parts of the reflector are complete. Since my dish is going to be mounted in an exposed location, I decided to strengthen it by adding bracing between the ribs about midway from the center. A framework was fastened to the center plate so that the whole antenna can be bolted to a mast.

Feedhorn Ideas

Because of the f/d rati of 0.5, the obvious fee choice becomes a horn. The theory behind horn design is not trivial. To make matters worse, there often is a vast difference between a design on paper and one that works. The horn shown in Fig. 5 has been field-proven on the 1296-MHz band by K9KFR and others. Horns of this type have about 8 dB of gain. Other types of feeds can be used; one good source of information is the RSGB book, *VHF-UHF Manual*, by Jessop and Evans.

Unless you can find a tin can that meets the dimensions shown in Fig. 5, you will need to make one. Using light-weight aluminum stock, I made a cylinder from a 18" × 28.25" piece. Next, a cap is fashioned to fit into one end. Small vee-shaped tabs are bent 90° and riveted to the cylinder wall. The result is a tube with an inside length of 16" and a diameter of 9".

The location of the tuned element is critical. A type-N connector should be mounted 2" from the rear wall. A 1/4-wave driven element (1.8" of 1/4-inch copper tubing or 1/8" welding rod) is adjusted by filing. Using approximately one Watt of power with an in-line wattmeter, file for best vswr. *Caution: The horn is emitting microwaves; keep hands and eyes away from the opening.* Be sure to use hardline for all connections.

It should come as no surprise that at this point the antenna is almost finished. Now the horn is mounted on the antenna frame with four sections of telescoping aluminum tubing.

The exact distance between the dish center and the horn must be found experimentally. The focal point will *not* be at the horn's outside edge, it will be inside the cylinder. To find the exact focus, the dish should be aimed at a signal source and the horn moved up and down until the received signal is at a maximum. If your 1296 receiving gear includes a low-noise amplifier, then one excellent signal source is "sun noise." Aim the dish at the sun, and your receiver should give a noticeable output.

The antenna's polarity is determined by the position of the driven element. Rotating the horn 90° changes the antenna from vertical to horizontal or vice versa. When the driven

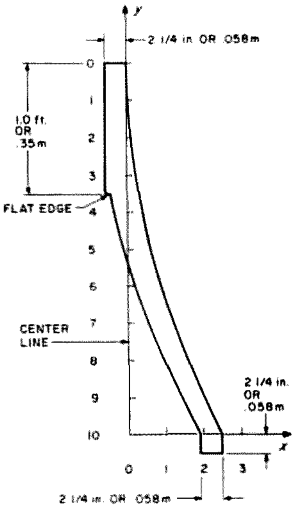

Fig. 3. Rib detail.

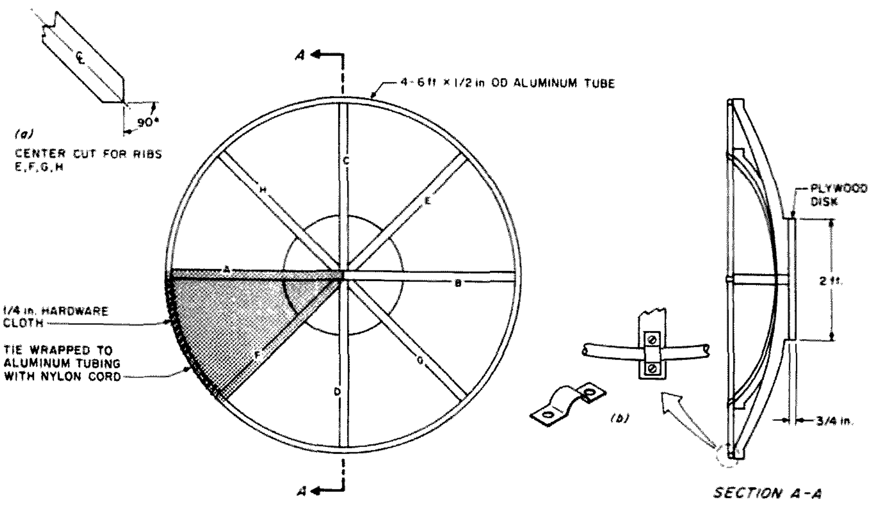

Fig. 4. Assembly of the ribs.

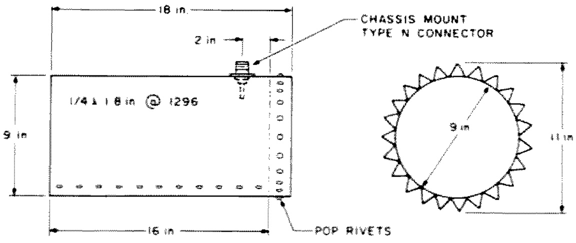

Fig. 5. Feedhorn design.

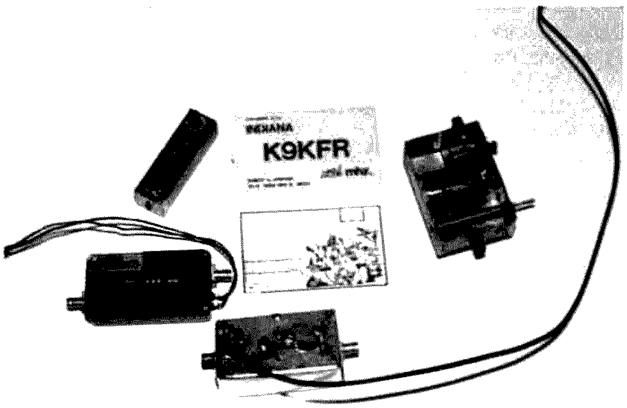

Photo D. Building a 1296-MHz dish need not be difficult, but it will require some home-brewing.

element is horizontal relative to the Earth, the antenna is horizontally polarized and is set for 1296-MHz tropo operation. Once the focus and polarity are set, bolt everything into place and start enjoying your new antenna.

Life on 1296

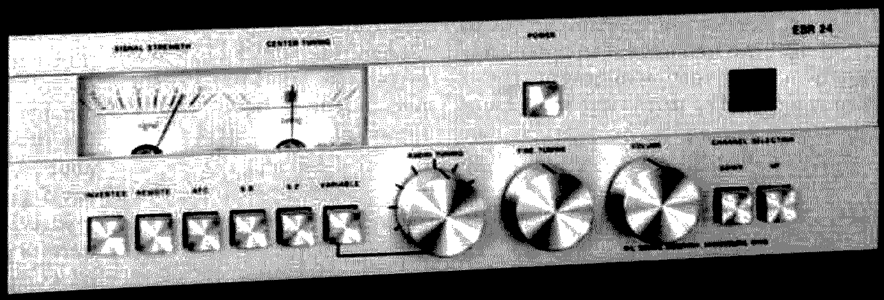
You might be interested in the rest of my 1296-MHz station. For receiving, I use a preamplifier made with an MRF901 transistor, followed by a Microwave Module that converts the signal to 28 MHz where an amateur transceiver is used. On transmit, a home-brew varactor tripler provides 3/4-Watt output on 1296 when driven with a ten-Watt, 432-MHz signal. This may not seem like much power, but I make the most of it by using hardline between the dish and the shack. Thanks to my dish antenna, the 1296 effort has been a success. The first two contacts were with K9KFR and WA8JHW, each more than 100 miles away.

This article is being written in the winter, and the dish has been stored away, safe from ice and other hazards. When warm weather returns, you can be sure that W8DJY will be back on 1296. In the meantime, plans are being made for a much bigger dish and a more powerful transmitter.

As you can see, building a dish need not be difficult. This project was the result of a lot of help and ideas from fellow VHF-UHF enthusiasts, including WB8EEX, whose garage proved invaluable, W8ULC, who handled the fancy footwork on the tower, and K9KFR, who patiently helped get a feed that worked.

About the only thing that can't be changed is the basic parabolic shape. Make the most of the materials that are available in your area; be brave; experiment! If you have questions, please include an SASE. See you on 1296! ■

ESR24 Earth Station Receiver



Full-performance Satellite TV Receiver

• All 24 Satellite Channels • Attractive Styling • Digital Display • Up/Down Channel Button Control
• Fixed and Variable Audio Tuning for all Subcarriers • Normal/Inverted Video Switching
• Signal and Tuning Meters • Single and Double Down Conversion Models • Afc for drift-free operation
• Remote Control and Remote Metering Options • Suggested List as low as $995.00

Job's Own LNA

– rolling your own takes patience

Yes, it *is* possible to home-brew a workable LNA (Low Noise Amplifier) for your home-brew satellite TV receiver! But to do it, you must have the patience of Job and start with a full head of hair!

We'll let you, the reader, decide as you read the article just how much patience we have.

In ham radio receiver terms, the LNA is the "front end" of the satellite receiver. Commercial units generally have about 40 to 50 dB of gain at 4 GHz. They usually are constructed of one or two stages of GaAsFET transistors and several stages of bipolar transistors to achieve the amplification desired. The GaAsFET transistors are a special type of transistor with a very low noise figure. They get their name from the material used to achieve the low-noise figure, gallium (Ga) arsenide (As).

This article describes the trials and tribulations that we went through in building the LNA for our satellite-TV receiving system. Although we had access to absolutely no test equipment for 4 GHz until after it was known to be working, we were very successful in getting the complete system going. We wish to share our hard-earned information with *73* readers who are considering building their own systems.

First, a little history. Our initial attempt to build an LNA used a commercially-available board which, for reasons to be discussed, will be nameless. The board was supposedly designed to work with Nippon Electric Company (NEC) NE21889 GaAsFETs. These FETs are expensive at $103.25 for two, but they have a noise figure of 1.2 dB at 4 GHz.

So, being the scroungers that we are, we attempted to substitute cheaper (higher noise figure) GaAsFETs. The result was two blown FETs that cost $62.50 and two grown men crying. We then bit the bullet and ordered two of the NEC FETs from its US distributor, California Eastern Labs (CEL).

With cold, dry weather, we were in a real dilemma. How do you protect a hundred bucks worth of minute transistors from static electricity while you are soldering them into the circuit? We finally decided that we needed a work area with a good ground and high humidity. Richard's front bathroom was selected to be converted to a reduced static work area. We turned on the hot water in the shower to steam things up.

A piece of copper braid wrapped around my wrist and grounded to the cold water pipes provided the ground needed. A large piece of copper-covered PC board also was grounded to the cold water pipe and was used as the work surface. We let the soldering pencil

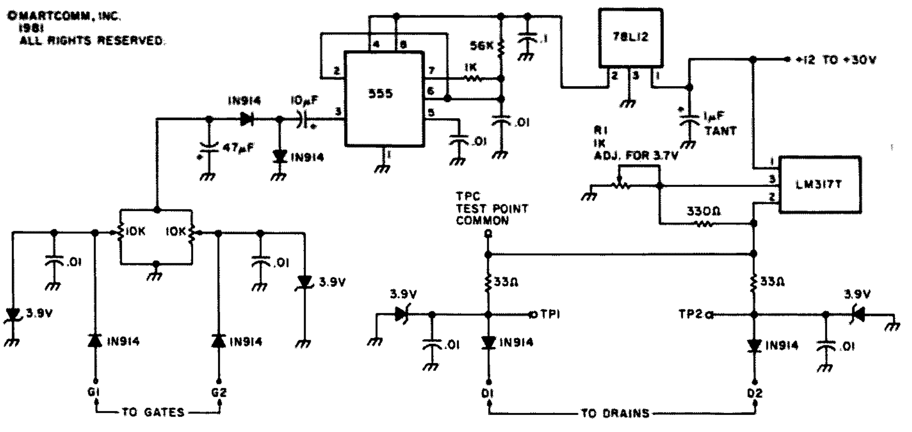

Fig. 1. Bias supply schematic.

heat up and then unplugged it from the ac line and grounded it with a jumper to the work surface for more static protection. I quickly soldered the first transistor in before the iron could cool. After I stopped shaking, we reheated the soldering pen and I soldered in the second transistor. It's amazing what lengths you will go to when a hundred dollars worth of FETs are at stake.

The LNA was mounted in a box made of double-sided PC board, with feedthrough capacitors supplying the correct operating voltages from a very simple resistive divider power supply. Next, we gave the LNA a try. It wailed like a banshee! In other words, it acted more like an oscillator than an amplifier.

How did we tell that it was oscillating without using test gear? We discovered that any oscillation within the 3.7-to-4.2-GHz band is immediately obvious on a TV connected to the receiver. If the oscillation is strong, there will be very prominent black bars on the screen regardless of where the local oscillator is tuned. If the oscillation is weak, there will be a very weak but still visible black bar. Black bars will occur twice, 70 MHz apart, within the tuning range of the local oscillator, if you are using a single conversion receiver (since you get both the signal and its image).

If the oscillation is outside the tuning range of the TV, however, it will not show up on the TV screen. If you can't see it on the TV and if you don't have a spectrum analyzer to test with, how do you know that it is still oscillating? Noise, noise, and more noise at the 70-MHz i-f stage.

What to do with the oscillating LNA? Start over! We wrote California Eastern Labs for their Application Note AN80903 that describes an LNA using the NE21889s. A prompt response from CEL brought it to us. In the CEL design, the LNA was mounted in a machined-brass enclosure. We could not immediately locate any half-inch-thick brass to make the enclosure, but Richard, scrounging through his junk pile, located a short piece of copper bus bar which was suitable. A little persuasion was applied to a local machine shop and presto, we had two nice machined-copper enclosures.

Since we thought it would be impossible to remove the GaAsFETs from the first LNA board without destroying them, we ordered two more NE21889s from CEL. At $103.25 for the pair, this project was getting expensive!

Richard arranged for a local print shop to make negatives for the printed circuit board to within .002 inch of the dimensions specified in the CEL Ap Note. We quickly made a board and waited for the second pair of transistors to arrive.

While waiting for the transistors, we did some serious thinking about a power supply for the LNA. As previously mentioned, we had already zapped two "cheap" FETs. We wanted a reliable LNA power-supply design that would protect the expensive little buggers. Many hours of design, building, and testing of circuits by Richard resulted in the LNA power supply board described here. We call it our "How Not to Gas Your FETs Bias Supply Board." It was designed specifically for a two-stage LNA using the NEC 21889 FETs.

Some criteria for the design: It should—

- Supply +3 volts for the drain and −3 volts for the gates.
- Power two stages of GaAsFETs.
- Require only one pair of wires for the LNA so the supply voltage, with proper blocking, could be carried on coax cable.
- Provide reverse polarity and overvoltage protection for all gates and drains.
- Regulate gate bias and drain voltage with a main-supply voltage falling anywhere between +15 and +30 volts.
- Have most parts available from Radio Shack.

The circuit described in Fig. 1 meets all of the design criteria. The input voltage, which can be from +15 to +30 volts, is applied to an LM317T adjustable voltage regulator, which reduces it to +3.7 volts. The +3.7 volts is then filtered by a 1-uF tantalum capacitor and fed through 33-Ohm current-limiting re-

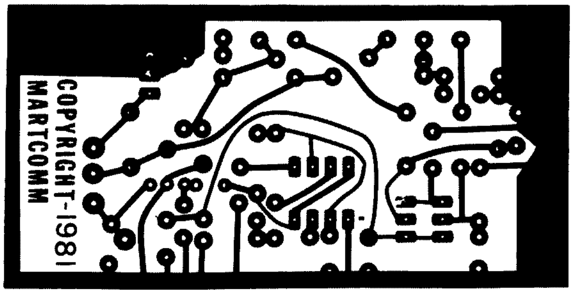

Fig. 2(a). PC-board layout.

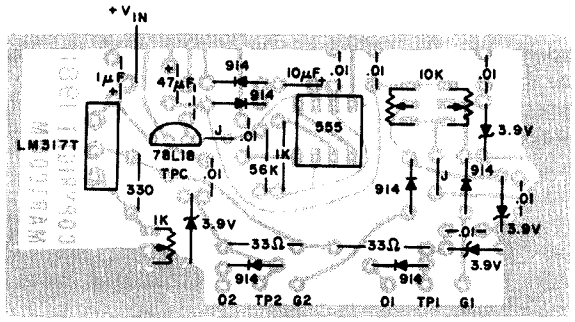

Fig. 2(b). Parts placement.

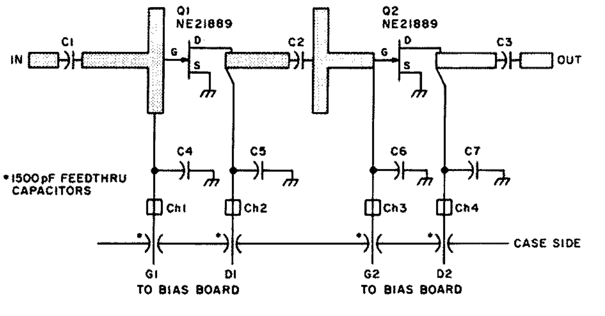

Fig. 3. Typical GaAsFET amplifier schematic.

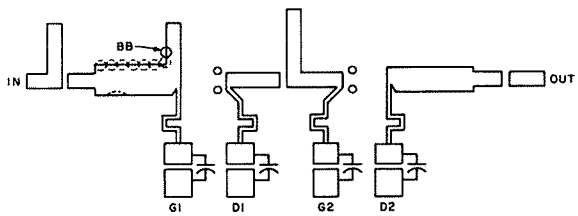

Fig. 4. Typical LNA board layout (not to scale).

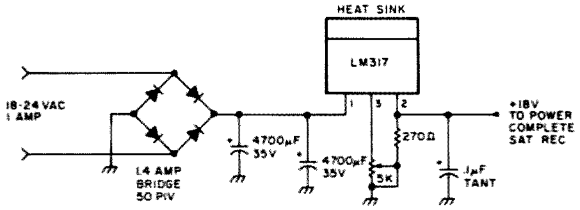

Fig. 5. Receiver power supply schematic.

sistors to the drains of the two GaAsFETs. The test points on each side of the 33-Ohm resistors are used to measure the voltage drop across the resistors and, therefore, the current being pulled by each FET. A voltage drop across the resistor of .33 volts equals 10 milliamperes of current being pulled by the FET. A 3.9-volt zener diode limits the maximum drain voltage, and high-frequency filtering is provided by the .01-uF capacitors. The voltage is then fed through 1N914 diodes for reverse voltage protection. This completes the drain supply.

We decided to generate the required negative voltage from the positive supply instead of going with a bipolar supply. Past experience has proved that for us, the negative-voltage regulator always fails first. With no negative bias, high-drain current would probably result, zapping the expensive FET. For the gate supply, the +15 to +30 volts is applied to a 78L12 regulator. The regulated +12 volts is used to supply a NE555 timer IC configured as a free-running multivibrator. The output of the 555 is rectified with a voltage doubler and filtered to give a negative voltage for the gate bias. The negative voltage is applied to two 10k-Ohm ten-turn pots. The zener overvoltage, diode reverse-polarity protection, and high-frequency filtering are the same as for the drain supply. A PC-board layout and parts overlay for the LNA power supply are shown in Fig. 2.

Everything was now ready for the arrival of the second pair of FETs. When they arrived, Richard soldered them in using a Radio Shack battery-powered, isolated-tip soldering pen that we had purchased for working with the GaAsFETs. By having Richard solder these in, we discovered that the guy who supplies the money for the FETs shakes the most when soldering.

After assembly of the bias supply board, but before connecting it to the LNA, apply +15 to +30 volts. With a voltmeter, adjust pot R1 for +3.7 volts at the test point TPC (Test Point Common). This will result in approximately +3 volts to the drains after the .7-volt drop across the reverse-polarity protection diodes. Set the 10k bias pots for −3 volts at points G1 and G2.

The supply is now ready for connection to the LNA, using the isolated-tip, battery-powered soldering iron, with the tip grounded to the LNA board. Refer to the "typical" LNA schematic, Fig. 3. Be very *careful* to connect the gate leads, G1 and G2, before connecting the drain leads, D1 and D2. With a voltmeter across the 33-Ohm resistor, + probe to TPC, − probe to TP1, adjust G1 bias for a .33-volt reading. This indicates that 10 milliamperes of current is being pulled by the

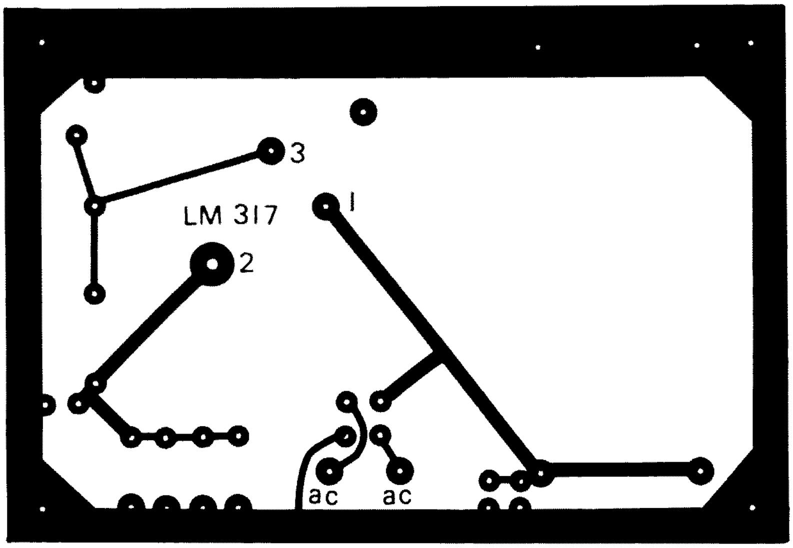

Fig. 6(a). Receiver power-supply PC board layout.

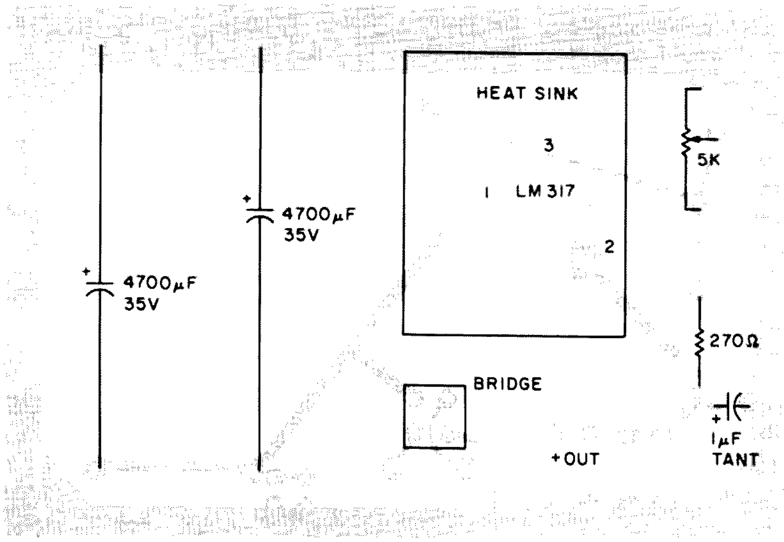

Fig. 6(b). Parts placement.

GaAsFET. Move the − probe to RP2 and adjust the G2 bias pot for a .33-volt reading. Now go back and check FET #1. As you adjust the bias pots, the current should *evenly increase*! If the current jumps or is erratic, the LNA is probably oscillating. How to stop oscillation is the subject of another article!

Using the above-described LNA power supply and tune-up procedure, the CEL LNA design came up beautifully, with no oscillation. Its two stages gave a solid, measured 21 DB of gain. We were unable to measure the noise figure directly, but the fellow with the test equipment said that it appeared to be very low, based on his evaluation of the ratio of gain to noise generated by the test equipment.

What type of picture do you get with a two-stage, 21-dB gain LNA that has an unknown noise figure? Very poor! After getting the first CEL LNA working, Richard was able to remove the NE21889s successfully from the commercial board. We built up a second board, using the cell design and our LNA power-supply board. Again, the CEL design came up with absolutely no problems. Now, by cascading the two boards, we were getting some results.

After optimizing the boards, which I will cover next, we have numerous transponders on SATCOM I above noise. We are located in the 32-33-dB footprint and the antenna is a home-brew 12-foot spherical. We have made comparisons of our four-stage CEL LNA and a 120-degree commercial LNA. Our home-brew LNA compares *very favorably* with the commercial unit.

Trimming an LNA for Best Noise Figure and Best Gain

After having gone through the misery of trying to build an LNA with almost no information and absolutely no test equipment, we now can describe some of the procedures we had to discover the hard way.

The first step is to prepare a work area so that you minimize the possibility of blowing those costly GaAsFETs. A piece of printed circuit board makes an ideal work surface. Again, you will need a good isolated-tip soldering pen. Ground the tip of the pen to the work surface with a jumper. The battery-powered pen sold by Radio Shack works great. You should ground yourself to the work surface with a piece of copper braid. You also will need an X-acto® knife, a BB or small ball bearing, a plastic tuning wand, and a steady hand. Glue the BB or small ball bearing to the end of the plastic tuning wand.

The LNA, as built, should produce watchable video in most areas of the country. With power on and a transponder tuned in, make sure that the correct current is set for each stage of the LNA (10 mA per stage for the NE21889). You should monitor the current of each stage as it is trimmed. Place the BB on the PC-board trace edge as per Fig. 4. Slowly move the BB around the outside perimeter of the striplines, keeping it in contact with the stripline. Monitor the quality of the received picture as you move the BB. When a point is found where the picture quality gets better, you need to add copper to the stripline. If the picture quality gets worse, you need to remove some of the stripline by making *very* light cuts. We only score the copper with the X-acto knife so that it can be soldered back together if needed. Make several trips around the striplines and note the effect before doing any adding or trimming. Make a log of the points where changes occur and see if they repeat each time you run the BB by them. After you are convinced of the points that need changing, then make the necessary adjustments. Copper can be added by salvaging a piece of foil from another piece of PC board or by using GC Electronics Silver Print paint.

After the adjustments are made, make a slight increase in the current for each FET stage while watching the picture quality. We have run the current up to 40 milliamperes on a stage with no oscillation. The first stage will probably have to operate at 8 to 12 milliamperes for best noise figure. Successive stages can operate at higher current levels for more gain.

The basic power-supply design (Fig. 5) and PC board layout (Fig 6) power the bias board and also our complete satellite TV receiver. There is nothing special about it except, again, that an effort was made to use parts available from Radio Shack. ■

Microwave Master

—you might not need a mountaintop

With the growing interest in satellite television reception, weather picture reception, and higher frequency utilization, the need for a better understanding of microwave principles becomes more important than before.

To better understand microwave techniques, we must first understand the frequency bands and the characteristics of the microwave spectrum in relationship to other lower frequency radio waves. As we know, radio waves travel mostly along the ground path and are not readily affected by mild changes in the weather or atmosphere. When we get into the microwave region, the characteristics are entirely different.

To begin, let us take a look at what microwaves are. Radio waves above the 1000-MHz level are called microwaves. It is a common practice to relate to this portion of the frequency spectrum in terms of Gigahertz (GHz), with a frequency of 1000 MHz being equal to one Gigahertz. The basic spectrum of microwave frequencies is made up of three very basic bands. These bands are: the S-band centered at about 3000 MHz (10 cm), the X-band at about 10,000 MHz (3cm), and the K-band at about 27,000 MHz (1.1 cm).

Table 1 shows the relationship between the bands by wavelength in both centimeters and inches, and Table 2 shows some of the services operating there. You will notice from the table that a full wavelength at the microwave frequencies is not very long. When we get into working with the construction of microwave equipment and subassemblies, these measurements will have a very significant meaning.

The first cavity magnetron was developed in Great Britain in 1940, after the publication in 1936 of two papers on hollow waveguides. These papers are: "Hyper-frequency Waveguides—General Considerations and Experimental Results" by G. C. Southworth, and "Transmission of Electromagnetic Waves in Hollow Tubes of Metal" by W. L. Barrow. During the period of early development around 1940, most of the experimental work was carried on in the Radiation Laboratory at the Massachusetts Institute of Technology. During this time, almost all experimental work in microwaves was directed towards the design and use of microwave radar equipment, due to the small size of antenna equipment required in the microwave region.

After the second world war, more efforts were made in other areas to the extent that today, almost all long-range telephone communications are relayed by microwave links. As scientific advances began in outer space, the role of microwaves became even more important. In fact, microwave technology has made possible many of the products used today in our homes, business, and in private industry. An example of a modern use of microwave technology is the microwave oven found in many homes and businesses.

Microwaves are also used in many of the security alarm systems found in business use and have been used by private industry for some time for cleaning of parts, removal of broken screws and bolts, and for controlling signal devices at railroad crossings and drawbridges. Another use with which almost everyone is familiar is the radar speed control devices used by police forces all over the country.

To understand microwave principles, we must first take a look at some of the characteristics of microwaves in relation to other forms of radiation. We must also learn what variables affect the microwave signal itself.

To begin, microwaves normally travel in one or all of four basic paths. These four paths are direct wave, reflected wave, surface wave, and sky wave. In most microwave installations, the direct wave is the desired path, although the reflected wave also may be of importance in some instances.

The direct wave is so named because of its direct path from one point to another. With optimum conditions, the most reliable communications can be ob-

Band	Frequency (MHz)	Wavelength cm	Wavelength inches
S-band	3,000	10	4
X-band	10,000	3	1.2
K-band	27,000	1.1	.44

Table 1. Microwave bands.

Satellite TV	3700-4200 MHz	8-7	3.2-2.8

Table 2. Some services operating in the microwave frequencies.

tained through the use of the direct wave.

The sky wave normally is considered to be a wave that has been reflected from the ionosphere, a region that extends from an altitude of approximately 30 miles on out to about 250 miles. In the area of satellite television or weather fax, a signal which is transmitted from a satellite is not considered to be sky wave but, instead, falls under the classification of a direct wave that has been retransmitted.

Surface waves are waves that travel along the surface of ground or water. They are mostly predominant at the lower frequencies. At microwave frequencies this mode of propagation is usually insignificant and in most cases may be disregarded.

The reflected wave is a wave that has been reflected from the land or water surface of the area between the transmitter and receiver antenna sites. A factor that determines the strength of the reflected wave is the type of surface that the wave is reflected from. Land is considered to be a poor reflector and will scatter the wave in many directions. Water is a good reflective surface and generally will reflect the entire wave in one direction. The reflected wave is only important when the reflected signal is picked up at the receiving antenna with a strength comparable to the strength of the direct-wave signal. At this particular occurrence, the reflected wave may either boost the direct-wave signal or cancel it almost completely. The determining factor at this time is whether the two signals are in phase with each other. If the two signals are in phase, or nearly in phase, or if the two signals are of nearly equal strength, the combined signal can be twice as strong.

However, if the two signals are nearly 180° out of phase with each other, there will be a reduction in signal strength since the reflected signal will cancel some of the strength of the direct-wave signal.

A phase difference between the direct wave and the reflected wave is usually introduced by the difference in the distance each wave travels. This difference may vary from installation to installation and can be anything from a fraction of a wavelength to many wavelengths. When the path difference is an odd number of wavelengths, the two signals (direct and reflected) will arrive at the receiving antenna in-phase. This is especially true when the wave is reflected at small angles of incidence, which cause a phase reversal of 180°. In the case of horizontal polarization, the phase reversal is nearly 180° regardless of the magnitude of the grazing angle. This is also true for almost all instances of vertical polarization in most point-to-point communications systems.

An interesting fact about microwave energy is that the signal tends to be slightly curved. This is because the signals travel through the atmosphere at speeds that depend on temperature, atmospheric pressure, and the amount of water vapor present in the atmosphere.

The following three conditions will have an effect on the microwave signal: The *higher* the temperature, the *faster* the signal; the *lower* the atmospheric pressure, the *faster* the signal; and the *lower* the water vapor content, the *faster* the signal.

With these influences, the net result is that the signal speed changes with altitude. Under normal conditions, the variation is a small and uniform increase in speed of the signal with an increase in altitude. In this manner, it readily can be seen that in a way, the microwave signal acts very much like a light beam. Just as a light beam can be reflected or bent, so can a microwave signal be reflected or bent.

Using the above information, we also can see that microwaves can be very reliable for communications systems. The most important factor is to ensure as direct a line-of-sight path from the transmitter antenna to the receive antenna as possible. With prior study of the potential path, it is really not too difficult to plan a microwave system. The thing to keep in mind is that the complete path of the microwave signal must be free of any obstructions such as trees, hills, or tall buildings. When transmitting over water, the reflected wave may play an important role in the received signal. When you are designing over-water point-to-point systems, it is very important to ensure that this reflected signal does not arrive at the receive antenna in an out-of-phase or nearly out-of-phase state.

A simple rule-of-thumb method can be used to determine possible antenna heights, especially for over water paths. The antenna heights chosen must satisfy the following relation: $\sqrt{2H_1}+\sqrt{2H_2}=S$, where H_1 and H_2 represent the antenna heights in feet above sea level and S represents the distance in miles between the antennas.

The next step is to calculate a correction height using the formula $H=\sqrt{S/F}$, where H is in feet, S is the distance between the antennas in miles, and F is the operating frequency in MHz. The required antenna height for each antenna is the sum of the tentative height and the correction height for each antenna, or, more simply stated, $H_1 + H$ and $H_2 + H$. If the values obtained are not convenient, then select new tentative antenna heights and perform a new calculation.

For example, if we assume a transmitting antenna height of 1400 feet and a receiving antenna height of 2000 feet at a distance of 100 miles, the computation would be: $\sqrt{2(1400)} + \sqrt{2(2000)} = 100$ (miles). The square root of the H_1 component is 52.92; the H_2 square root component is 63.25. This gives us a total of 116.17 miles. It is then quite evident that one or both of the contemplated antennas are too high. By using the S value of 100 and working backwards with the formula, using H_1 as the base antenna and recomputing for H_2 height: $100 - 52.92 = 47.08$ squared $= 2216.53$ divided by $2 = 1108.26$ feet. Therefore, the

new height that meets the relation is 1108 feet for H_2. By the same token, we could have kept antenna H_2 at the height desired and recomputed the height for H_1.

Using the corrected figures for antenna heights of 1400 feet for H_1 and 1108 feet for H_2, we now can compute the correction heights for both antennas at a frequency of 1296 MHz: $H = 660\sqrt{100/1296} =$ 183.33333 feet. This gives us a final figure of antenna height for H_1 of 1400 + 183.33 or a total of 1583.33 feet and for H_2 1108 + 183.33 or a total of 1291.33 feet. Given the figures above, we can now look for possible sites to install antennas.

Of course, we may not always find the ideal spots for our antenna construction. In this case, we go back and recalculate using different antenna heights (plus elevation above sea level) to obtain a relative figure equal to the desired distance figure. Sometimes just one or two feet may make the difference at the receive end.

In any attempt at microwave, if at first you do not succeed, try again at another location or change the height of one or both of the antennas. In selecting a good antenna site, a very good aid to locate the ideal sites is a topographical map of the area locality of choice. A source of information for obtaining topographical maps is at your state capital. Try writing a letter either to the State Department of Natural Resources or the State Forestry Division. There is a fee required for copies of these maps, but it is usually very small when one considers the information that can be obtained and the time that can be saved. Happy hamming on the microwave bands.■

CW Interface

—let your computer do the copying

It is one thing to obtain software to decode Morse code with your computer, but it is quite another to process the audio signal delivered by your receiver in such a way that the computer can use it. This article will describe one approach to solving this hardware problem and also describe the construction and operation of an interface circuit using these principles.

I will assume that you already have software for decoding Morse and will describe the needed hardware. An example of such a program was presented by Thomas[1] in the December, 1977, issue of *73*. For our purpose, we will assume that your software requires a TTL signal that is logic low during the key-down intervals and logic high during the key-up intervals.

Proper operation of your decoding algorithm will require the presence of one logic level during the key-down interval and the opposite logic level for the key-up state. The computer must see only one or the other of these states at any one time, and they must change only when the state of the desired signal changes. State changes should not be affected by interfering signals or random noise.

An extremely simple circuit could successfully be used to interface a computer to a ham receiver if the audio signal produced by the receiver were perfect (absolutely noise-free and of constant level and frequency), but the circuit must be considerably more elaborate if the computer is to perform properly with the imperfect signals typical of ham-band operation.

Typical receiver output during CW reception on today's ham bands presents a difficult problem when attempting to decode the signal with a computer. Even if the operator is using a selective receiver (400-Hz bandwidth) designed for CW reception, several different signals usually will be present in the audio. The signal that the operator is trying to copy probably will be tuned for his preferred pitch, while the others will be present at other frequencies. The desired signals probably will be the strongest, but the others may be fairly strong also.

In addition to these interfering Morse signals, there will be noise. In the signal output that is available to the computer interface circuit, we will have, in general, voltage due to our one desired signal and also considerable voltage due to all the other signals and noise being processed by the receiver. In order to decode the desired signal successfully, we must have a way to detect the voltage due to our desired signal while ignoring as best we can the other signals and noise.

Desirable Interface Qualities

We can summarize several design objectives for our receiver-computer interface. First of all, it should be (as always) small, inexpensive, and easy to construct and operate. Second, it should respond only to one very narrow band of audio frequencies, for maximum immunity to adjacent signal interference and noise. Third, the output should be bistable and TTL-compatible for proper interpretation at the computer input port; the output should be either logic high (+3.5 to +5 volts) or low (0 to +0.6 volts) and never in between. Fourth, the decision threshold of the detector should be adjustable to allow the interface to operate properly with both high- and low-level audio so that the operator is not forced to operate a certain audio gain setting which may not always be convenient. And fifth, the interface should work while the speaker of the receiver is operating, so that the operator can hear the code while it is being decoded to allow detection of computer errors (decoding errors can be expected under adverse reception conditions).

Theory

Fig. 1 is a block diagram of one approach to doing the required processing of the receiver audio. The first stage is a limiter which produces a known signal level at the beginning of the circuit; this allows the rest of the device to be designed optimally for this level. The limiter is followed by a 4-pole active bandpass

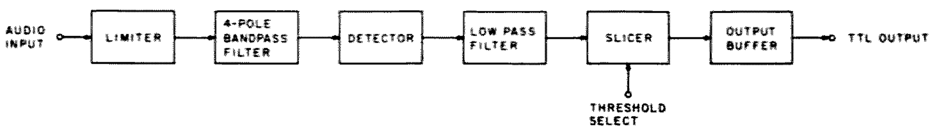

Fig. 1. Interface block diagram.

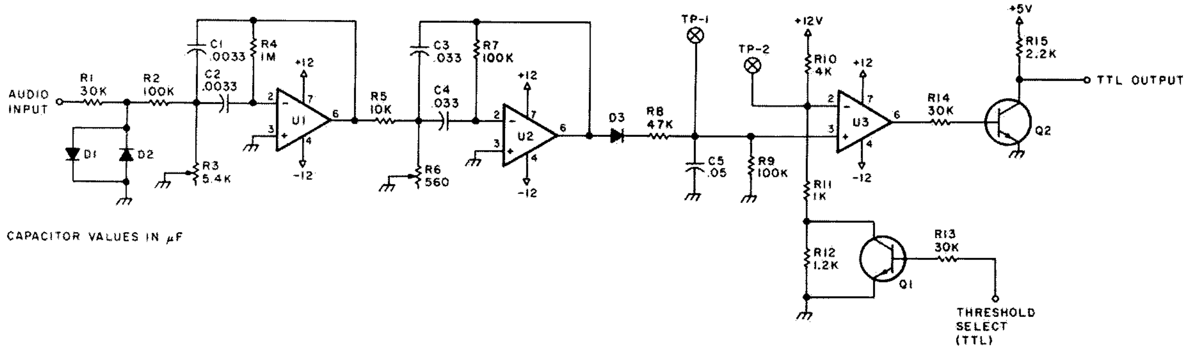

Fig. 2. Interface schematic.

filter. The filter is tuned to 950 Hz and has a design bandwidth of 80 Hz. This filter works by amplifying the signal about 16 times at its center frequency and attenuating signals not within its passband. This ensures that the detector stage only sees voltage due to the desired signal. The detector itself is merely a half-wave rectifier (a diode), and it is followed by a simple RC low-pass filter so that the output of the filter follows the pulse shape of the signal as closely as possible. The output of this stage will be maximum when the signal is present and minimum when there is no signal present.

The slicer stage decides whether there is a signal present or not. It does this by comparing a preset threshold voltage to the voltage it receives from the detector and filter. Whenever the received signal exceeds the preset threshold, the slicer quickly switches its output state from -10 V to +10 V.

Under ideal conditions, the output voltage at this point in the circuit would never exceed this preset threshold when only noise and interfering signals were present. If the voltage exceeds the threshold only when the desired signal is indeed present, no errors will be generated. If this is not the case (and usually it is not), errors will be generated whenever the combined level of the interference and noise exceeds the threshold. (The slicer will change state.) As soon as the voltage subsides, the slicer will revert to the correct state. For optimum operation of the overall hardware/software system, your decoding algorithm should be designed to ignore these spurious but unavoidable brief state changes due to noise.

Finally, the output buffer converts the signal levels produced by the slicer (which are incompatible with the computer input gates) to correct TTL levels.

The Circuit

Fig. 2 shows the schematic of one circuit that meets the design objectives outlined above. I know that not many people build anything exactly as it is described in a magazine article (neither do I), so I will not only describe this circuit but will also give a little of the thought behind the design choices that I made.

Diodes D1 and D2 form the limiter, and these should be silicon types to give a limited signal of about ±0.6-V peak at this point. R1 is used to keep the input impedance of this interface high so that it may be used across an existing high-impedance output of your receiver (the anti-VOX output on a Drake R-4, for instance), in parallel with whatever you normally connect to that output. So, this circuit can simply be added to your existing layout with little effect. Also, because the signal level is limited to 0.6 V, only about a 1-volt peak of audio signal is required at the input to this device. On my receiver, the anti-VOX output puts out more than enough voltage at moderate speaker volume levels. Another advantage of permanently connecting the interface to a high-impedance point in your receiver is that the speaker and headphone outputs can be used or disabled without affecting the connection to the interface.

Components R2 through U2 make up the 4-pole active bandpass filter. My first prototype used only a single-stage filter (2-pole), but I found that it was allowing too much interference from adjacent signals. I therefore decided to go to a 4-pole design, with the resultant much steeper skirts to the passband. The filter design itself was arrived at with the help of articles by Stark[2] and Stewart[3] in past issues of *73*, regarding active filter design. Each stage of the filter is designed for a Q of 10. The center frequency of stage 1 is 975 Hz and that of stage 2 is 930 Hz. This yields a 3-dB passband of about 80 Hz and very steep skirts and requires only 2 ICs. (Strictly following the criteria used by Stark would have yielded filter stages with higher Qs, but also would have required a total of 4 ICs and several more resistors in the design. My approach sacrifices some skirt steepness but eliminates many components. That was my choice.)

Each filter stage is designed for a gain of 4.8 so that at the overall filter center frequency of 950 Hz the complete filter has a gain of about 16. With the 0.6-V peak input, about 10-volts peak output is developed at the detector. If you would like to try your own hand at designing the filters (perhaps you'd like to use capacitors you have in your junk box or a different center frequency), use the procedures given in either of the above two articles but be careful to keep the first resistor (R2) around 100k or greater so that the input is not loaded down. R1 and R2 form a voltage divider, and smaller values of R2 will require more drive voltage from your receiver for full limiting.

Diode D3 is the detector, and R8, C5, and R9 form the simple low-pass filter. The filter components were arrived at by experiment, the goal being use of a physically small capacitor at C5 and optimum following of the keyed signal pulse shape at speeds up to about 30 wpm. These values meet these criteria well.

U3 is the slicer, and the resistor network R10, R11, and R12 with Q1 produce a software-controllable variable threshold. Using the indicated resistor values, when Q1 is not conducting, the threshold at pin 2 of U3 will be about 1.8 volts.

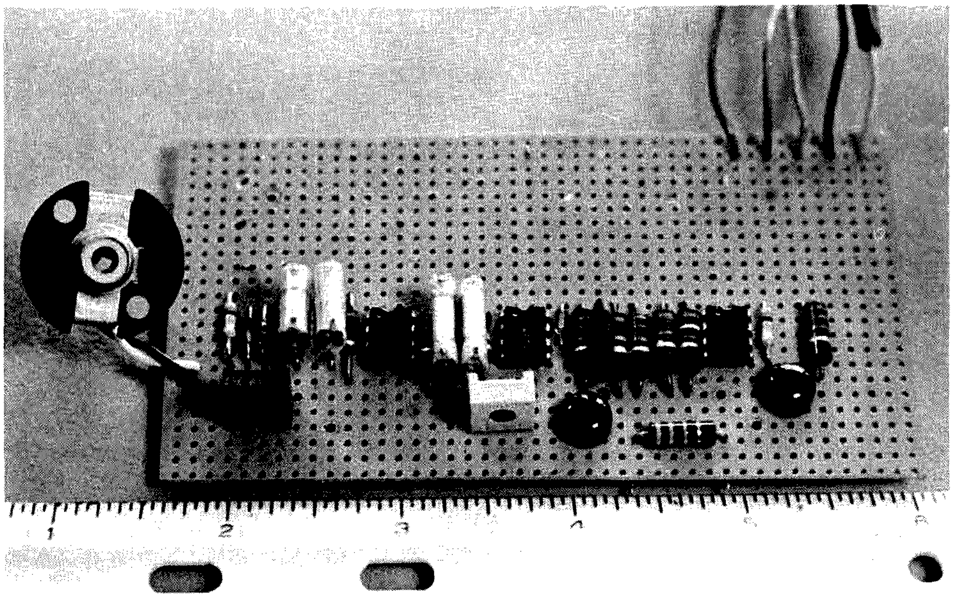

Photo A. Interface prototype.

When Q1 *is* conducting, the threshold will be lowered to about 1.0 volt. Thus, by tying the input to R13 to one bit of an output port, you can control the slicer threshold through software. This could have been done with a mechanical switch, but I wanted to mount this circuit deep within the bowels of my computer, controlled only by my commands via the keyboard. This approach took a while to design, but it requires very little additional space on the circuit board.

Under normal conditions, one would use the higher threshold for the best performance. But when you are operating with a signal level that is not strong enough for full limiting and noise conditions are favorable, you can extend your operating range by lowering the threshold to about 1 volt.

The output of U3 is either about +10 or −10 volts depending upon the detector output to U3. These levels could not be applied safely to the TTL input port of a computer, so the buffer stage, Q2, was added to provide a signal that always remains within the TTL operating range of 0-5 V. The output of Q2 can be tied directly to one bit of an input port.

With this circuit, the idle, or no signal, state of the output is logic high (+5 V). When a signal is present, the output drops to 0 V.

Construction

Photo A shows the prototype of this circuit in final form. My next step will be to reassemble it on a plug-in vectorboard for mounting directly inside my computer. As you can see, it requires a total area of about 2 by 4½ inches on the board. None of the components dissipates an appreciable heat, so it is safe to mount them adjacent to each other (but be careful not to short any leads). The wires visible in the upper-right portion of the board are for my temporary power and computer connections to the circuit.

All resistors used in the circuit need be no larger than ¼ Watt. I used what I had in my junk box, so some of the resistors in the photo are ½ Watt. Capacitors C1 through C4 should be high-quality polystyrene or mylar™ (and not disc ceramic) as pointed out by Stark. Try to get values for R2, R4, R7 as close to those listed as possible—although the final adjustments of R3 and R6 will compensate for any variations from the optimum values. The values for the two trimpots, R3 and R6, need be considered only approximate, and the final adjustment of these two can be expected at about mid-range if the indicated values are used.

Diodes D1 and D2 must be silicon types (small signal) and D3 can be either silicon or germanium. C5 can be disc ceramic. Q1 and Q2 are any *general* purpose silicon transistors capable of operating with a 2-mA collector current and a beta of at least 100 (type 2N3566 were used here).

As you can see from the photo, it is not necessary to etch a PC board. All three ICs are type 741. Power supply voltages of +12, −12, and +5 volts are required, but these should be available readily in most computers.

Alignment and Check-Out

The only alignment required is that of properly tuning each filter stage. For this, you will need some type of known frequency audio input. Apply an input to the circuit at 975 Hz, at a level of 1 volt or greater, and adjust R3 for maximum output at pin 6 of U1. Change the input frequency to 930 Hz and adjust R6 for maximum as measured at pin 6 of U2. You then should find that the 2-stage filter has a center frequency of about 950 Hz and an 80-Hz passband. With an input signal level sufficient for full limiting, about 10 volts (peak) signal should be available at the output of U2. Under these same conditions, the voltage at TP-1 should be about 3 volts (dc). As a final check, you can confirm that the output of Q2 is +5 V with no signal applied and 0 V when a 950-Hz signal is present.

Operation

Once the above initial alignment is completed, no further adjustments need be made. When operating the interface, all one must do is tune the desired CW signal properly so that it falls within the filter passband and adjust the receiver's audio level to an optimum value. These two tasks, however, are not quite as easy as they sound.

The easiest way to tune your receiver for optimum operation of the interface requires *an* oscilloscope. While there is another technique, it has some severe limitations. I will first cover tuning with an oscilloscope, and then the alternative if a scope is not available.

Oscilloscope Method

For the moment, let us assume that you have a dual-trace oscilloscope at your disposal for operation of your receiver-computer combination. Connect one channel to TP-1 in the circuit and the other channel to TP-2. Use dc coupling for both. Use a vertical sensitivity of 500 mV per division for both channels and a sweep speed of 10 ms per

division. Adjust the baselines of both traces to exactly the same point near the bottom of the graticule. You should then obtain a display similar to that shown in Photo B when a properly tuned signal is being received.

In the example, both traces have their zero baselines one division from the bottom of the graticule and the vertical and horizontal settings are as recommended above. The trace visible about one division above the center of the graticule is the TP-2 threshold voltage (about 1.8 V). The other trace shows the leading edge of a CW pulse that is being received. This display shows just about ideal reception conditions and is what you should strive for in your tuning. At the baseline of the signal trace, we can see that there is almost no noticeable noise between CW pulses. This situation is rare but does happen occasionally. (Indeed, the photo was taken during reception of a very strong off-the-air signal at about 25 wpm.)

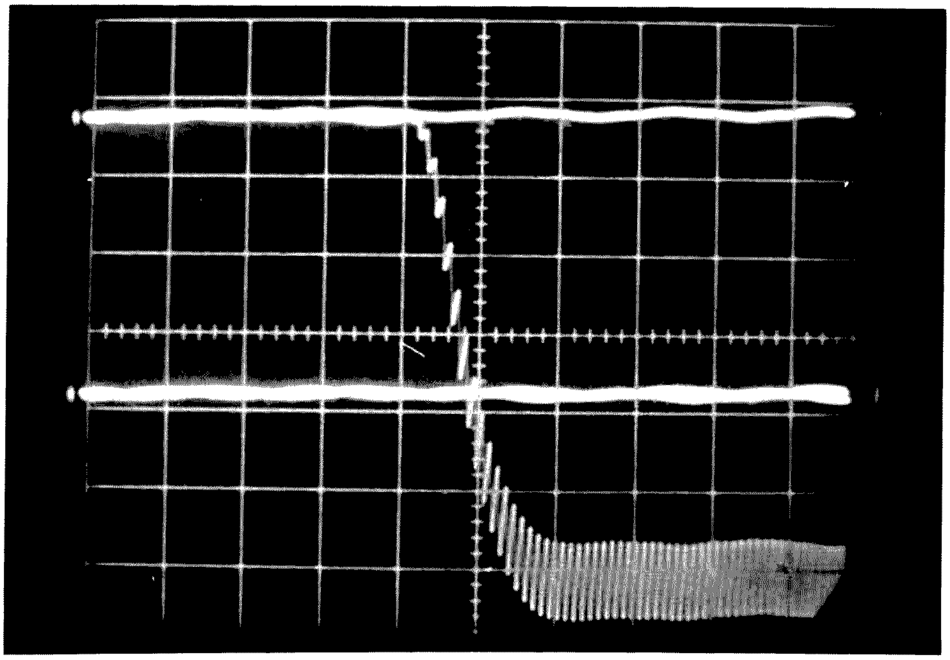

Photo B. Oscilloscope display.

The first step in tuning is to tune the receiver until the tone of the desired CW signal is centered in the filter passband, as evidenced by a maximum signal amplitude for the signal pulse on the oscilloscope display. This will take some care, due to the narrowness of the filter passband. After this condition has been achieved, the next step is to optimize the level of the receiver audio which is being fed to the interface. Making this choice optimally will require a little experience on your part (which will come with time), but I can give you a few hints.

Your primary goal is to maximize the signal-to-noise ratio at the slicer (which is what the TP-1 signal shows). This condition will give you the minimum error rate out of the slicer stage, and hence within the decoding algorithm in the computer. Since you have a limiter in the first stage of the interface, you will notice that you can increase the level of the desired signal only up to a point, beyond which it will no longer increase.

You will notice also, however, that if you continue to increase the drive level, the amplitude of the noise and interference evident between pulses *will* increase. This is undesirable. Therefore, you want a condition where the signal gives the greatest difference between the peak of the signal and the peaks of the noise and interference as viewed on the scope. Next, decide whether the normal (high) threshold voltage is best or if the lower threshold would be better. Ideally, the threshold of the slicer should be halfway between the signal peak and the noise peaks. Then, by monitoring the oscilloscope display, you can ensure that the signal remains optimally tuned even if your receiver drifts a small amount or if the noise and interference conditions change.

When using this type of display, it is convenient to have the current slicer threshold (TP-2) superimposed on the display with one channel of the scope, but it is not absolutely necessary. If you have only one single-channel scope, just remember where you have set your threshold, or use an external voltmeter to monitor it while you display the TP-1 signal.

Alternate Tuning Method

As you probably have guessed by now, without an oscilloscope it would be very difficult to adjust the receiver for the optimum conditions described above. This does not mean that you cannot tune it to work fairly well most of the time, however. A VTVM attached to TP-1 also will give an indication of when you have reached maximum signal strength, but its fluctuations with the signal will be much more difficult to interpret. You also will have very little ability to judge the noise conditions between the pulses, but, if you are having a problem, you can compensate for these by doing a little trial and error with the detection threshold and seeing which one works better. You will find that you must tune the receiver slowly in order to find the very narrow passband of the filter.

Summary

This circuit evolved over several months of experimentation and testing, and I think it is a good compromise between circuit complexity and satisfactory performance. I think you will find, however, that while the computer can do a very good job of decoding well-sent Morse code under good reception conditions, the machine is no match for the human brain when it comes to poorly-sent code or very adverse noise or interference conditions. ■

REVIEW

KDK FM-2025A TWO-METER FM TRANSCEIVER

When you think about two-meter transceivers, what brand names come to mind first? Chances are, you'll name one of the big "full line" imported labels. There is nothing wrong with this except that you may be overlooking some of the other guys. What about firms like Azden and KDK? Both concentrate on selling a specific but high-quality line of radios. Until recently, I dismissed firms like these as "also-rans." Then I had a chance to review KDK's new FM-2025A two-meter FM transceiver. Now I'm a firm believer.

The FM-2025A is the latest in a series of two-meter mobile rigs that are manufactured by Kyokuto Denshi Company and imported into the United States under the KDK name. The 2025 represents a rather substantial departure from the earlier models, which included the 2015R, a great rig once you modified it. The staff at KDK has learned its lesson well; the FM-2025A offers many of the features that today's ham expects yet it remains simple and straightforward to operate.

Diode Matrix Programming

Like many of its modern day counterparts, the 2025A utilizes microprocessor control. In what seems like a step into the past, KDK has chosen to use a binary-coded-decimal diode (BCD) array to act as a program for the computer. Shades of the venerable Icom IC-22S. Or is it? Twenty-five diodes are used to program such functions as the low-frequency band edge, high-frequency band edge, transmit high-frequency band edge, a choice of 5-kHz or 12.5-kHz steps, the standard repeater offset, and band-scan step size. The unit comes factory programmed in a manner that will appeal to the vast majority of North American users. However, if you move overseas or have a need to operate outside of the US amateur allocation, it's a straightforward task to reprogram the KDK to meet your new needs.

If you are like me, most of your two-meter operating is done on a few local repeaters with occasional forays to other machines if you're traveling. Perhaps the easiest way to use the KDK is to program your favorite machines into the memories. There are two sets of memory, five channels each. You can use the channels independently or in a duplex mode where you receive on the "A" channel and transmit on the "B" selection. Since I frequent only a few repeaters, I find myself using the duplex mode. That way, I don't have to worry about switching the repeater offset selection when I change frequencies.

If you use more than five channels on a regular basis, then you may want to make full use of the ten memories by employing the offset switch for everything but the repeaters with oddball splits. The FM-2025A includes a nicad battery that provides internal backup for the memory when the radio is switched off. The infinitesimal 57-nano-ampere current drain allows the battery to last for as long as one year between charges.

Scanning

The FM-2025A offers two modes of scanning. You can search the ten memories for an open frequency or for a frequency in use. When the channel changes status, the receiver starts scanning again. If you want to lock the rig on frequency, just flip the scan control to the HOLD position.

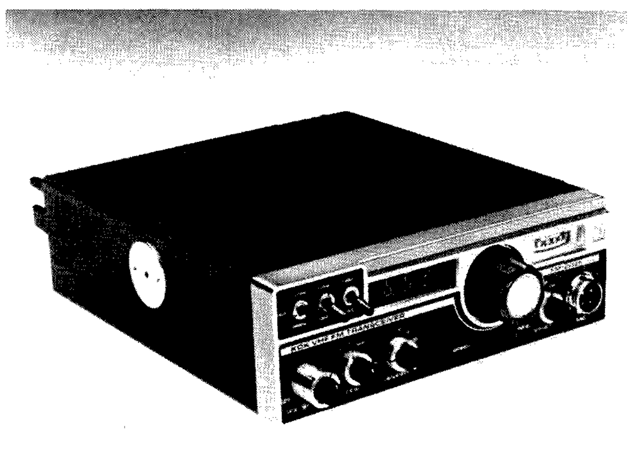
The same options are available in the band-scan mode. The scanning starts with the frequency stored in memory A5 and proceeds upward to a limit determined by the contents of B5. But you can't fool the rig; if the B5 frequency is lower than the A5 selection, there will be no scanning.

The nice thing about the KDK's band scanning is its zero detector. This ensures that receiver scanning stops only on the center of a signal. The only difficulty I encountered came when I tried to scan near 144.000 MHz. An internal spur caused a false locking there.

One useful 2025A extra is a built-in tone switch. An internal switch allows you to select between a continuous tone or a half-second tone burst. There is no need to run out and buy a new encoder if your favorite machine goes private. There is easy access to adjustments for the tone generator's frequency and output level.

Procedures like this are explained well in the instruction manual. Unlike many manuals that accompany new gear, the KDK book is written with the assumption that the reader has some intelligence; it presents more than just an idiot's guide to installation. You'll even find four pages of technical and adjustment information plus a larger-than-usual schematic diagram.

The KDK's construction is nothing short of rugged. The vast majority of the rig's circuitry is on two boards, with the digital-based control circuitry on one and the rf blocks on the other. The lack of interconnecting wiring harnesses and cabling leads me to believe that the 2025A will easily withstand a harsh mobile environment.



The KDK VHF FM-2025A transceiver.

The back panel includes a jack for an external speaker (and once you have tried this you will never settle for a built-in speaker again), antenna and power connectors plus an accessory connector that includes microphone input, audio output, transmit-receive switching, and connection to the 13-volt dc power supply.

Moving back inside, I noticed that all of the frequency generation and most of the audio circuitry was centered around integrated components. The rf section still utilizes a fair number of discrete semiconductors, but the chip-based technology is rapidly closing the gap.

Plus and Minus Points

With a growing trend towards higher power for two-meter transceivers, the 2025A holds it own with a choice of two power levels, either one of which can be set between 3 and 25 Watts. If you need still more power, then consider an amplifier; you also get the added advantage of a receiver preamplifier that way. Unlike most of the other new FM rigs appearing on the market, KDK retains the traditional d'Arsonval meter movement for the power-out and signal-strength measuring chores. I can't knock the newfangled LED bar displays without trying them, but I do know that the old-fashioned meter makes the radio look more "professional."

Among the bells and whistles that you won't find on the 2025A is a priority channel. Nor is there a provision for up/down scanning via switches on the microphone. For me, the lack of these features had no effect on my operating style.

Perhaps the biggest drawback of this easy-to-use radio is the close proximity of the volume/squelch, mode, and memory-select knobs. They are all the same size and easily confused if you don't glance down at the rig.

On an overall basis, I give the FM-2025A high marks. It represents a substantial step forward in ease of operation.

While it doesn't resemble the mission-control-panel look prevalent on a lot of new rigs, it is a sophisticated, feature-laden radio. It should be especially popular with amateurs who want a radio they can tinker with. The 2025A certainly proves that KDK is more than just the "other guys" when it comes to building radios.

In late 1981, the FM-2025A was priced at $299. For more information, contact *KDK Distributing Co., 617 South Gallatin Road, Madison TN 37115*. Reader service number 476.

DFD SYSTEMS RT-89 RTTY SYSTEM

The DFD Systems RT-89 package is a disk-based RTTY system for Heath/Zenith H89 and H8/H19 computer systems. It runs under the Heath Disk Operating System (HDOS), providing unmatched features and flexibility for the serious RTTY enthusiast. The system is designed to operate on a single-drive, 48K machine with plenty of space left over for disk read/write files and memory buffer space. All input/output operations are buffered and interrupt driven, allowing true full duplex (send-while-receive) operation and real-time disk file read/write capabilities without loss of data.

There are 66 commands implemented to configure the system and control program operation. In addition, a special file, "RTTYINIT.TTY", is automatically read at program start-up time to establish the initial system environment. This file can be individually tailored by the user to automatically boot the system in any desired configuration.

RT-89 will operate at speeds of 60, 66, 75, and 100 wpm in the Baudot mode, or at any standard ASCII baud rate from 110 to 19,200. Automatic synchronous idle (diddle) may be selected at any of these speeds in either mode, and an automatic down-shift-on-space (DSOS) feature is selectable in the Baudot mode. All CW identification is automatic, including an ID at nine-minute intervals during any single transmission. This feature can be disabled with a keyboard command if desired. In addition, a CWID shift control and transmitter on/off control are available from the computer.

An automatic disk log is maintained each time the transmitter is keyed, and manual entries may also be inserted on the log at any time with the N= command. The time of day is automatically recorded with each log entry, so the system log can also be used as the station log if desired!

System line width can be varied from 20 to 80 characters since the H89/H19 terminal has a full 80x25 line display. The screen is split into four functional areas: a receive window, a transmit and command window, a split-screen and status-display bar, and a "times square" moving-marquee format on the 25th line that displays the transmitted data as it is actually transmitted. This latter feature is useful when the transmit buffer has been preloaded or a disk file is being transmitted, since the transmit window displayed the buffer contents as the transmit buffer was loaded, and the 25th line actually displays the buffer data as it is being sent. Therefore, the operator always "sees" what is being transmitted over the air at any given time. The sizes of the receive and transmit/command windows are dynamically variable and may be changed at any time during system operation. In fact, any commands may be issued at any time (except during transmit), so there is never a need to stop the program to reset any parameters as there is on some other systems.

The system may be directed to ignore carriage returns in the receive window, thus "packing" a maximum amount of data on the screen. The carriage returns are not ignored, however, on the printer or disk files, so the actual format of the received data is not lost (you can write on the printer, read and write on disk, and receive and transmit all at once, in real time, due to the interrupt-driven I/O structure).

Any number of files can be written to or read from disk at any time, and the printer may be turned on and off at will, independently for received and transmitted data!

A variable-length "word-correction buffer" is provided to allow correcting of keyed input data prior to its release to the system. The length of this buffer may be set from 1 to 80 characters, and facilitates backspacing over entry errors and correcting them before transmission. There are actually two cursors displayed on the screen: a flashing underline cursor which indicates where the word correction buffer starts, and a destructive block cursor indicating the next location that will be occupied by keyed input. In addition, the system can be directed to automatically "wrap around" when the end of a line is reached and no carriage return is keyed. In this event, the system will automatically move the last word keyed to the next line, if it is incomplete, and issue the carriage return itself.

An unusual and very enjoyable feature provides the ability to process RTTY pictures. The system may be placed in the PIX mode, and overlining will be allowed on input and output files and the printer. In addition, three off-line programs are included with the package that will allow one to edit PIX files with the standard HDOS text editor, and automatically compress and expand those PIX files to conserve disk space. PIX files received over the air are actually compressed before they are written to disk, and compressed PIX files on disk that are read for transmission are automatically expanded by the system at transmit time!

In addition to the unlimited disk file capability, there are three temporary single-line buffers that can be loaded and read out using the three colored function keys on the H89/H19 keyboard. These are handy for holding calls of current stations in QSO or repetitive contest information. Other function keys can be used to insert the current date and/or time in the transmit buffer. (The time of day is also always maintained on the split-screen bar.)

In operation, the TX or TXF commands will put the system in transmit mode, and a CONTROL-C will terminate the transmit mode. Data can be entered into the transmit buffer while in receive mode, and that data will be transmitted the next time TX (transmit) mode is entered. TXF (transmit fast), on the other hand, will not send the data in the transmit buffer, but will only send data keyed from the keyboard. TXF, therefore, is used to answer a quick question or to send a quick message without sending the data in the transmit buffer. After TXF, more data can be entered into the transmit buffer, if desired.

Disk-based commands include opening and closing disk files for either read or write, displaying directories, deleting files, exchanging files, and swapping disks in drives 1 and 2.

Performance

The RT-89 system has performed very well for more than a year of operation on both the HF and VHF bands. The system was designed to support Navy MARS message traffic as well as amateur traffic, and has now replaced all mechanical teletype equipment at Navy MARS stations NNN0AFL and NNN0ZVW. No system problems or failures have yet been encountered at either station.

The system includes complete operational documentation and directions for interfacing the computer to a terminal unit. The system has been successfully interfaced with a HAL ST-6, commercial and home-brew Flesher TU-170s, and the iRL-500. The iRL-500 interface was the easiest to accomplish since it already had inputs and outputs to directly interface to the computer at RS-232 voltage levels.

Each RT-89 system is personally generated for each purchaser to include the station callsign. This callsign is permanently displayed on the split-screen bar during system operation and is used in generating the CW identification. Minimum hardware requirements are an H8 (with an H19 terminal) or H89 computer, a single disk drive, and 48K memory. HDOS is also required to operate the system. The package consists of the programs on a 5¼" diskette and an instruction manual. The cost is $39.95. For further information, contact *DFD Systems, 4805 N. 107th Street, Omaha NE 68134*. Reader Service number 477.

INTERFERENCE HANDBOOK

Whether the alphabet-soup nomenclature is TVI, RFI, or EMI, interference is a constant threat to the radio amateur, lurking in the shadows, waiting to

turn docile neighbors into a horde of angry enemies. Even though the war against interference has just begun, there is hope for the ham-radio army. Radio Publications' new book, *Interference Handbook*, is destined to become a bible for the tactics-minded foot soldier. The author of *Interference Handbook* knows what he is talking about; William Nelson WA6FQG is the veteran of sixteen years of trench warfare as an RFI investigator for Southern California Edison Company.

RFI has plagued us ever since Marconi made his first transmissions nearly a century ago. While modern-day legislators and manufacturers grapple over a long-term solution, the problem gets worse and the poor radio amateur is caught in the middle. The approach that *Interference Handbook* takes is best summarized by the quote: "The purpose of this handbook is to outline the many sources of interference; explain how to eliminate or reduce them; and tell you how to protect yourself against RFI. The causes and cures of RFI are discussed in nontechnical language that is easy to read and understand."

The topics discussed range from interference caused by home appliances and the RFI emitted by power lines to the misunderstood role that hams and CBers play in causing and solving interference problems. Along the way, the author gives case histories based on his years as an investigator.

Tips for locating interference with inexpensive gear are accompanied by descriptions of commercial and homemade cures. The contents will be of interest to anyone who deals with electronics. This could include the members of a radio club interference committee or a music lover who is plagued with automobile ignition noise. The book is rounded out with a listing of addresses for gaining help from manufacturers.

Interference can work both ways as evidenced by recent experiences at the *73 Magazine* ham shack. Several months ago, a pulsating noise of unknown origin kept us bewildered (and off the air) for several weeks. More recently, a neighbor has complained about TVI that may be the result of our station. In both of these cases, a volume like the 247-page *Interference Handbook* would have helped to reduce the mystery and aggravation for everyone involved.

A paperback edition of *Interference Handbook* is available from the publisher, *Radio Publications, Box 149, Wilton CT 06897*, or *73's Radio Bookshop, Peterborough NH 03458.*

LETTERS

QRZ CONTEST?

The weekend is here, I can't wait to get my cup of coffee, go downstairs and turn on the rig, and relax with some CW. Cranked up the old workhorse, my TR4-C, switched on the keyer. I love CW, my phase of enjoying ham radio, and spend most of the time on 20 meters and a little on 40 meters.

Here comes the audio, and what? Not again! The entire band loaded! Another contest? I thought they just finished one; you know how time flies. I must admit I have been in only one contest, in the early 60s, and cannot remember what it was for, but learned it was not for me. There are no redeeming factors in them that I can see. A field day or emergency preparedness operation so as to be able to get a station on the air fast in almost any location, portable, of course, to assist those in need of help, I am all for without exception, but to sit for 12 or 24 hours at a key or a microphone causing a traffic jam worse than the California freeways ever saw is a gross waste of time and energy.

I enjoy a good rag chew—or at least to find out more than a QTH and a name that's in the *Callbook*—talking over your experiences, experiments, good or bad, is a greater way to enjoy one's on-air time.

Let's think about it; contest weekend as it appears to me seems to relate itself to the opening of hunting season, the night before everyone participating making final preparations, checking their "guns" for the big day. From cannons to peashooters they are all ready. The clock is ticking away the last few minutes before the action begins. The beams are poised at each other, power supplies humming away, fingers begin twitching, one ready to send, one ready to record the contacts, then bang! A solid wall of rf rips through the ether and for the next day the battle for the climb to the top rages on. Stepping on each other, over, under, and around. When the period of time for the contest is over and the electromagnetic radiations clear, the battlefiled can be seen strewn with broken and mangled coffee cups, smoking ballpoint pens, splinters of pencils, and scraps of paper. The casualties are entering the "hospitals" with keyer finger, tennis wrist, another form of keyer finger, and ear-ring: a new one, being a depression in a circular fashion around both ears, manifested by a constant series of tone bursts that won't subside.

Why so many contests? Aren't there enough awards to be gotten on one's own without the additional promotion of contest after contest? I would like someone to reply and let me know.

Now don't get me wrong. I have gotten a few of those symptoms myself. What I am trying to say is those who prefer contests are good hams, they enjoy their phase of ham radio, a great hobby filled with very nice people. But all I ask for us in the apparent minority is that on those special weekends, those who sanction such contests *think*, think of the other hams who are not participating and leave at least 10 or 15 kHz aside for those of us who would like to just get on and relax with a good QSO, be it CW or SSB.

Why should the bands be totally monopolized during these periods? A lot of us just do not have the time to spend on the bands and really look forward to our weekend operation.

THANK YOU, ERIC

As a subscriber, I feel it is my duty to inform you of the good job you are doing. I am a new subscriber to your magazine and I love it! I am 13 years old and a General class ham. My father is also a ham and he likes your magazine, too. Between my father and I we receive *QST, Ham Radio, CQ, 73,* and *CVRA-SERA Journal*. We enjoy your magazine the best. The $25 is well worth it. I find many interesting articles in your magazine. In *QST, Ham Radio,* and *CQ* I rarely find a really good article. Many times the advertisements are the best things in *QST*! I can't say *QST* is a bad magazine—it has many important references. The other magazine (journal), *CVRA-SERA Journal*, is a great magazine. I find it and *73* the most interesting.

Thank you for your time. I just wanted to tell you how great your magazine is. Keep up the good work!

Eric Lassiter KA4KEG
Danville VA

WIN SOME, LOSE SOME

The last of the ham radio publishers bit the dust! I never thought you would pass us off for the quack electronics, but my new December issue with satellite TV, computer scanners, and all really opened the old eyes. I think I'll go back to model trains. I get enough of the electronic garbage at work all day. NO renewal for me next spring.

Ed Chenoweth K4HYG
Zephyrhills FL

Sorry to lose you, Ed, but we do have to bring news of what is happening in electronics to those amateurs who are helping the hobby to grow. . . who are interested in things beyond spark gaps. I realize that not all hams are going to be inventing and pioneering new techniques, but

I had hoped that those who are more interested in taking a free ride on the shoulders of those who are doing the work would at least be honorable enough to read about it and cheer them on instead of trying to shoot them down.—Wayne.

KNIT PICKING

Seldom do I write to the editor of a magazine, but every once in a while something will catch my eye. Such was the case when you asked in the October *73 Magazine* what we could do to spur the growth of ham radio.

Let me state that I am flatly opposed to no-code licenses. We already have them in the form of citizens band communications (I use the word "communications" with some reservation in this case), and I for one don't want 15-meter phone sounding like that. I really can't imagine that you do either.

Now to the basic question: What can we do?

1. We can exert pressure on the Federal Communications Commission through our elected representatives to take the tricks out of amateur exams. For example, a friend recently took (and passed) the Extra class examination in Boston. Part of his code proficiency test involved the apparent word "Springfield," but on the tape it was sent "Cpringfield." Granted, this quickie will determine if the examinee is paying absolute attention, but does it prove anything else? Is this the type of thing one would encounter in a normal QSO (which the tape is supposed to emulate)? I think not.

2. We can stop regarding ourselves as an elitist group. While my previous reference to citizens band could be construed as elitist—and perhaps it is—we must recognize that our hobby is no better than that of anyone else. If a CBer wants to be a CBer, then so be it. If an audiophile gets enjoyment from his "thing" then let him. We should not continue with the attitude that everyone in electronics either should "progress" into the ham fraternity or be relegated to second class. Perhaps if we are less pushy more people would *want* to join us.

3. Along the same lines, we should make more of an effort to help the newcomer. We spend a lot of time and effort getting people into ham radio through Novice classes, but how many Novices have given up on our hobby because the Techs, Generals, Advanceds, and Extras were too busy with their own interests to give a hand *after* the newcomer got that much-anticipated ticket? If you're not really sure of what you're doing and there's no one to help, amateur radio can be pretty confusing. Take the time to help a Novice; you may be saving tomorrow's Extra class licensee.

4. Again, along the elitist line, we need to have more of those "in the know" willing to make what they know readily available. It does not seem consistent to this writer that an editor of a widely-read ham publication could advocate the spread of our hobby on the one hand and then ask $1,000 or more for a speaking engagement at a hamfest on the other. Granted, Dayton and Birmingham can probably afford this tariff, but Windsor (our local hamfest) can't, and Windsor is more likely to touch a greater number of new and prospective hams in central Maine than are Dayton and Birmingham combined. Please don't take this as a personal attack, Wayne, but you *did* ask for constructive ideas.

5. We need more affordable equipment designed for beginning amateurs. Unfortunately, our hobby is pricing itself out of the reach of many would-be joiners because they can't afford a Kenwood TS-530, an Icom 720A, or an Astro 150. What we need are more Ten-Tec Century 21s that let the little guy get his feet wet with new (a Novice doesn't need the problems which often come with used gear), reasonably priced, and effective equipment.

6. Finally—for now, at least—we need effective representation in the FCC. Some government commissions are required to reflect in their membership the interests of those that they regulate. Why not a ham as a required commissioner, and a CBer, too? Who knows better what we want than one of our own? Certainly not some politician from the "in" party who had the misfortune of losing in the last election.

Well, Wayne, there you have it. I hope this letter will prompt others to put on their thinking caps and come up with more and different ideas. I wouldn't even object if theirs were better.

Bill Crowley K1NIT
Hallowell ME

No offense, Bill; the $1,000 goes for a special fund for promoting amateur radio, not into the general coffers. Without that limitation I've found that I am getting dozens of invitations to talk... few of which would be possible for me. Thus, this is a filter... and also a benefit for amateur radio. You're right about the tricky exams... there is no excuse for them. There will be cheaper ham gear for beginners when we have enough beginners to make it profitable to make the stuff. Remember that plenty of equipment has been put on the market in the past, but it has not been continued due to an almost total lack of newcomers. And look what happened to the newcomer magazine, Ham Horizons!*—Wayne.*

THE HEATH SNOOZE

I have just finished the conversion of my Heathkit clock as stated in the November issue of *73 Magazine* ("Extra Accuracy for Heathkit Clocks," page 124).

There were no conversion or cross-reference lists at any of the local Radio Shack stores for a switch with part number 275-430. I could have used another RS switch, but keeping with amateur radio practice I quickly realized that the Alarm Set Switch (SW3) could be used and the old Snooze Alarm Switch (SW2) wired in its place. It is a little cumbersome to use in setting the alarm, but then I don't use this function. My clock works as stated in the article.

The wiring is done in the same manner as Art N5AEN stated, and the new SW3 is wired as shown in the clock manual.

Others may be interested in this miser's scheme to beat down the rising cost of ham radio.

I've enjoyed *73 Magazine* and will continue to do so.

Jack Garner KB7HH
Phoenix AZ

THE BIG ZAP

When I read *QST*, I first look at the silent keys. With your *73*, I read the editorial. I was especially interested in the radar devices you use and test. My mobile friends tell me the devices are not very good anymore. The policeman with the gun pops it on and gets a reading and you are hooked. No more carrier to seek out. I don't travel much anymore, but I do have a new approach to traffic tickets.

I propose a tape-deck player and a specially-prepared deck that starts with fifteen seconds of soft music, and then a convincing commercial announcer who breaks in with the news that the USA is being attacked by USSR missiles and the President is on his way by helicopter to the Virginia underground shelter...all citizens are to go to any nearby shelter. News flashes give reports of missiles twenty minutes from Chicago, Detroit, Washington...

I think by this time the trooper is on his way and you are free to go to your destination.

Just don't get stopped by the same guy the second time.

Ed Kirchhuber K4JK
Elkmont AL

Fiendish... I like it! The radar gun? I've only run into one once in New Hampshire so far, so it isn't much of a problem here. In that case, I got plenty of warning before I even got close due to the sensitivity of the superhet detector and was safely not transmitting on two meters when I went through the check point. Your detector should pick it up a half-mile to a mile away and give you plenty of warning to stop transmitting so you won't rack up a speeding ticket even when you are moseying along at 55 per. The officer generally takes a shot at a car ahead of you and you pick up that blast. This also gives you a chance to check your speed... which averages around 70 mph on most of our interstates.—Wayne.

GUS TRAVELS AGAIN

Those of you who have been around ham radio for more than a few years undoubtedly remember Gus Browning's fabulous DXpeditions of the 50s and early 60s. Well, W4BPD is back at it again and will be sending us monthly reports on the progress of his current round-the-world trip. Welcome aboard 73, Gus!

This little episode is being written while we are at anchor down in Florida awaiting a few minor repairs to be completed on the boat, but by the time you read it we will be somewhere in the Caribbean. We have named the ship *DX* since DX is what it's all about with us. Our mail address from now until this trip is completed is just "DX, 29039, USA."

A friend of mine talked with me up at DXPO 80 last September and asked me the question, "Have you ever thought about another DXpedition, Gus?"

You know what my answer was ("I have the time if you have the money"), and he said that money was no problem! It ended up that a boat was purchased and the old rat race of getting it shipshape for a real DXpedition began. The result is that here we are about to take off for the *complete* Caribbean tour; we'll go to every country down there that we can get permission to operate from. (They tell me that licensing is no problem at almost every one of them.)

This feller Wayne Green must have lots of pull somewhere because both on our way from Annapolis to Beaufort, South Carolina, and then again from Beaufort down here, I saw a sign on the Inland Waterway on the left side each time with the numbers 73 on a *green* background. And this Wayne Green don't fool around, neither, because when I mentioned writing a series of letters for *73 Magazine*, he said, "Don't stand there, start writing." So here I am doing just that.

This DXpedition should be considerably different from the others I have been on. This is planned to be an island-hopping DXpedition with inland excursions when it's possible and worthwhile from a DX viewpoint. We will be going by the seat of our pants all the way. This DXpedition by boat sure will be a lot better than the other ways I have used before, and it sure will be lots cheaper to charter a ship than to spend anywhere from $100 on up per day the way I've done it many times before. Since 99% of our traveling will be sailing, using the wind for power, it will be very interesting to see how our overall expenses compare with those of trips when other means of transportation were used.

The purpose of the first portion of this trip will be twofold: We will be shaking down the boat and we will be trying to see how we get along with each other being cooped up over long periods of time in a small space. There are three of us—myself, my XYL, Peggy, and Sam, a WA3 from the Washington DC area who purchased the boat. So far we are quite compatible, though at times a little touchy with each other, which we all expected before we ever got started.

Our tentative plans are to cover the Caribbean, probably taking until the next hurricane season, which starts next June. Then we will sail back to Beaufort to have the boat gone over with a fine-tooth comb and to visit all the grandchildren, the kids, and our friends. We'll restock the boat's larder, tighten up all the bolts and nuts, and then take off for the Panama Canal, the big, wide Pacific, and all those countries out there waiting for us to Dxpedite. If things are still "go," then we will continue on around the world, hitting as many spots as we can along our line of travel. We won't mind deviating from this line of travel a few hundred miles when, from a DX viewpoint, it looks like that's what we should do.

The very first thing we all agreed upon was that we wanted this trip to be a safe one. Since we have no set date to be anywhere along our route, we can always wait for the weather to get right before we depart from spot A to go to spot B. If all three of us like a certain place and want to spend a few more days or even weeks there, we will do just that. This will more or less be a leisure trip with DXpeditioning a first priority on our list. Right now, we are at the creeping stage; we hope to be at the walking stage when I write the next installment, and at the running stage from there on out.

We have a very good ship, an O'Day 37 (measuring 37 feet long and 11 feet across). How would you like to make something like this your complete home for up to five years? It will be on the rough side, but we will be in there trying our best to stick it out. Our ship is fully equipped with all the very latest gear. We have a satellite navigator that does a better job of pinpointing our position than most maps. We have a good radio direction finder, a good VHF transceiver, and, of course, a sextant, which I have practiced on for months. I still need more practice to get good on it. We have a huge pile of maps and charts but will need many more when we get to the Pacific and other oceans on our way around the world.

We will be taking it easy along the way and hamming as much as possible. We plan to use both CW and SSB on equal terms, going by the apparent needs of the fellows. We have the full Ten-Tec line of gear, their Omni-C, Hercules linear, electronic keyer, and antenna tuner for the long wires we may put up for the low bands. I cannot get over the Ten-Tec's fast break-in, the no tuning when you change bands, and the almost silent receiver when you disconnect the antenna. As a back-up, we have Ten-Tec's Delta. Our antenna is a TET and it will get a real test of endurance on this trip. As you can see, we're delighted with the equipment we have.

QSLs will go out three different ways. When we have time after the trip, every QSO in the logs will go out via bureaus. The second way of QSLing will be direct to those who send their cards to out "DX 29039 USA" headquarters and contribute $1.00 to help us defray the cost of QSLs, postage, and Girl Friday making them out. The third method will be direct from the spot where we work you or, if necessary, from the next spot we operate, to those making a $2.00 contribution to help us with expenses. (We do not expect to come anywhere near breaking even on our expenses.)

I don't think we can help anyone with 300 or more countries, but we might be able to help you if you have 200 or so. Maybe we will help some of you on 40, 80, or 160 meters. Later on we may use other means and ways of communications. We are, of course, open to your suggestions. We may or may not follow them, but "try us"—hi.

On CW, look for us 25 kHz from the low end, except on 160, 80, and maybe even 40. On SSB, when we are not under FCC rules, we will try using more or less these frequencies: 28490, 21190, 14105, 7090, 3790 kHz; and on 160—who knows, hi. But once we settle down on the frequencies we want to use, these will be where we will always be found, plus or minus QRM. I can promise you I will never get mad at anyone on the entire trip. A real nuisance to us may have a difficult job getting our QSL for his contact—the last laugh will be us doing the laughing, hi.

Up to now, there has been very little contributing or donating by anyone, so I am under obligation to just a few and I know who they are. I don't mind tail-enders or any other way you can come up with to get your call in my log. I try to work the weak ones first, so if you are QRO please go QRP if you want to work us first, hi. At times we will QSY into the Novice bands and will usually be tuning in the parts of the band Generals can use. But you had better have wide shift-split capabilities, or you may miss us. Occasionally, we will use transceive, but don't depend on this mode for many contacts with us. I say get yourself an outboard vfo and join in with the real DXers.

There will not be any of this list type of stuff on this DXpedition—if you want to QSO, get in there and work me. I don't want any of this stuff: "Gus, so and so said you are Q5-S7"; I want to hear that report and call myself without any assistance from helpers on the sidelines.

That's it for this episode, fellows—73 de Gus BPD.

Gus Browning W4BPD

HAMS AND COMPUTERS

Shh! Keep this quiet! Don't tell anyone, but I think microcomputers are taking over amateur radio.

Take last Friday, for instance. I'm working this station on CW—AF2M, I think the call was—and he's telling me about his rig, the weather, and all those other things that make QSOs so interesting. Then, all of a sudden, something must have blown in his shack because he just keeps sending "599, 599, 599. . ." After about 10 minutes of having my signal verified, it dawns on me—AF2M is a machine! Egad! This is worse than CB. At least on the chicken band you pick up animals, not androids.

It's scary. So scary, in fact, that I decided to write a column about ham radio and microcomputers. Here it is but don't tell anyone. I hate to be an alarmist. Where the heck did I put my nightlight?

ELEMENT 1—CROSSWORD PUZZLE
(Illustration 1)

Across

1 Letters and numerals
8 Below high frequency (abbr.)
9 Direct memory access (abbr.)
10 Computer lingo
13 Package type (abbr.)
15 Operating position
18 ____ line
19 Former big-time computer manufacturer (abbr.)
20 Program that revises (2 words)
22 And off
23 Data processing (abbr.)
25 Bulletin board (abbr.)
27 Semiconductor type (abbr.)
29 GOSUB

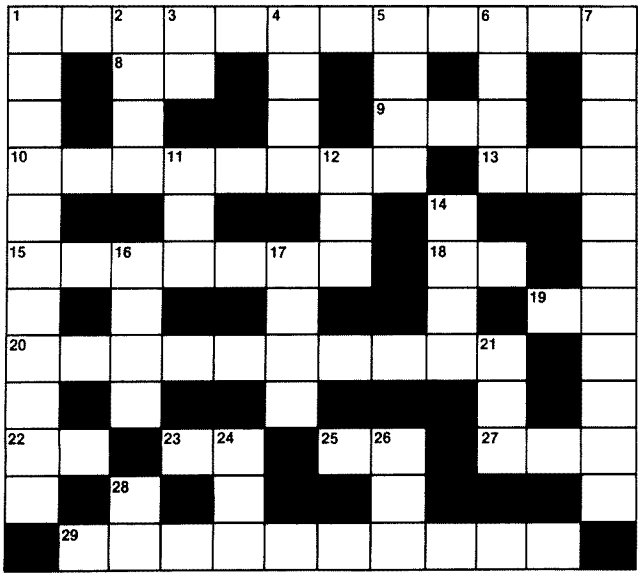

Illustration 1.

Down

1 Computer use
2 Scheme
3 Below VHF (abbr.)
4 They bought micro for shuttle (abbr.)
5 Statement of condition
6 "Only" type of memory
7 User
11 Crummy software often runs out of this
12 Golly
14 Instruction
16 To follow immediately
17 Bright diodes (abbr.)
21 Memory type (abbr.)
24 Cycles in a second
26 Smallest computer unit
28 μ

ELEMENT 2—MULTIPLE CHOICE

1) Computers can exchange information by using a code known as ASCII. What does this acronym stand for?
   1. American Standard Code for Interchanging Information
   2. American Standard Code for Information Interchange
   3. American Standard Code for Interconnecting Information
   4. American Standard Code II

2) Who was Herman Hollerith?
   1. Father of the punch card
   2. Father of punched paper tape
   3. Inventor of the floppy disk
   4. Inventor of the CRT

3) What are "Napier's Bones"?
   1. The remains of August Napier, inventor of the first analog computer
   2. The first pocket calculator, named for the device's ivory color
   3. A figment of the imagination
   4. Ivory rods which, when placed next to each other, can be used for multiplication calculations

4) An "automaton" is:
   1. A mechanism under the constant control of its own resident intelligence
   2. A mechanism under the constant control of a human or other external intelligence
   3. A mechanism under the constant control of a programming routine previously supplied by an external intelligence
   4. A waste of time

5) How many laws of robotics did Isaac Asimov detail in his book *I, Robot*?
   1. One 2. Two 3. Three 4. Four

ELEMENT 3—TRUE-FALSE

	True	False
1) HAL, the computer in *2001: A Space Odyssey*, was built at the Hal Plant in Urbana, Illinois, on January 12, 1997.	____	____
2) Speaking of HAL, his name stood for **H**euristically-programmed **AL**gorithmic computer.	____	____
3) The word "robot" was coined by Czechoslovakian author Karel Capek in his play *R.U.R.*	____	____
4) An early electronic computer, **EN**IAC (1946), contained 19,000 vacuum tubes.	____	____
5) After ENIAC, there was a computer called MANIAC.	____	____
6) PASCAL, the computer language, was named after Blaise Pascal, a 17th century French philosopher.	____	____
7) The "Computerist's Code" states that a computer user should never use his equipment to harm anyone.	____	____

8) BASIC is a high-level language. ______ ______
9) Bubble memory uses microscopic magnetic bubbles. ______ ______
10) CPU stands for "Control Programming Unit." ______ ______

ELEMENT 4—HIDDEN WORDS
(Illustration 2)

Hidden in this puzzle are words representing 15 different computer terms. The words are formed in any direction—horizontally, vertically, or diagonally, forwards or backwards. As you find each word, circle it.

THE ANSWERS

Element 1:
See Illustration 1A.
Element 2:
1)—2. And you know what great stuff American Standard makes.
2)—1. Ever noticed how these cards are only a little larger than a dollar bill? That's because HH used the dollar bill of his time (1890) as the template for his card. He invented the card and its reader for use in the US census.
3)—4. Scottish inventor John Napier (1550-1617) developed this precursor to the slide rule.

A	L	P	H	A	N	U	M	E	R	I	C
P		L	F		A		O		E		O
P		A			S		D	M	A		M

Illustration 2A.

4)—3. 1 is an android, 2 is a robot, and 4 is what noting the differences is.
5)—3. And if you break one of the three, you'll get a robot fine.

Element 3:

1)—True Long way from the ST-5000, Dr. Chandra.
2)—True Try saying that 10 times, fast.
3)—True Rossum's Universal Robots.
4)—False Ha-ha; slightly under 18,000.
5)—True Engineers just love snappy acronyms.
6)—True Blaise Pascal (1623-1662), who, after a day of philosophizing, would tinker with his adding machine.
7)—False The computerist's what?
8)—True Also the most popular, as if you didn't know.
9)—True And if you look through a microscope, you can even see them move.
10)—False Central Processing Unit.

Element 4:

See Illustration 2A.

SCORING

Element 1:
Twenty-five points for the completed puzzle, or ½ point for each question correctly answered.

Element 2:
Five points for each correct answer.

Element 3:
Two and 1/2 points for each correct answer.

Element 4:
Two points for each word found.

Are you digitally inclined?

1-20 points—Still mad at the government for outlawing spark.
21-40 points—Thinks computers might have a future.
41-60 points—Likes to play with display computers in stores.
61-80 points—Owns a nice, sensible computer system.
81-100+ points—Home-brews own computer.

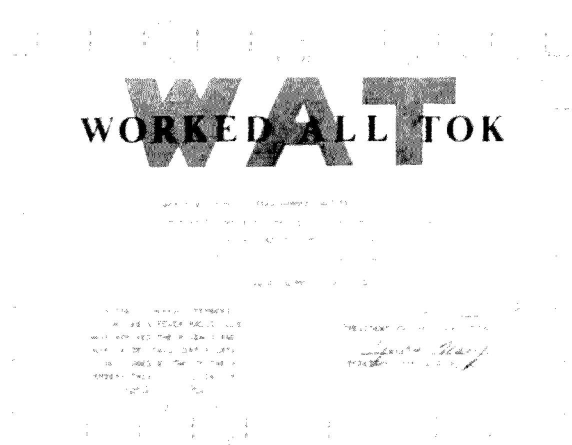
Oak Harbor WA 98277

WAT AWARD

The Cabin Fever Radio Club of Tok, Alaska, offers a certificate for contacting three amateurs in Tok. There are no band or mode restrictions. However, all contacts must be made after December 15, 1980, to be considered valid.

To apply, prepare a list of contacts in order by callsign. Include the name of the station operator, the date and time worked in GMT, and the mode and band of operation. QSLs not required. Amateurs located in Tok include AL7O, AL7BO, AL7BV, and WL7APG.

Send your application with $2.00 or 10 IRCs to: Cabin Fever Radio Club, Box 451, Tok AK 99780.

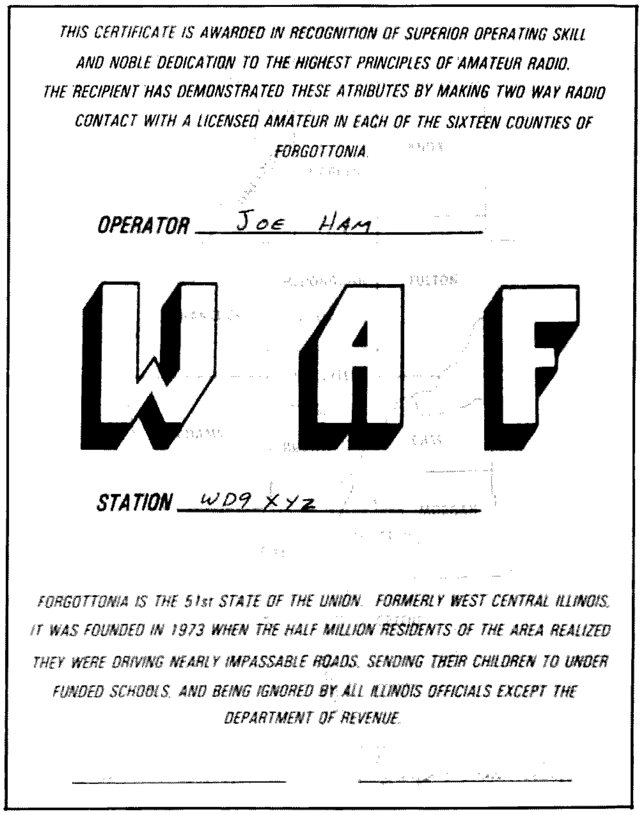


WORKED ALL FORGOTTONIA

Announcing the awards program sponsored by LEARC, the Lamoine Emergency Amateur Radio Club of Macomb, Illinois. The Worked Forgottonia award is issued amateurs who confirm contact with three (3) licensed amateurs of Forgottonia. The Worked *ALL* Forgottonia is awarded operators confirming contact with at least one amateur in each of the sixteen counties of Forgottonia.

What is Forgottonia? It is the 51st state! It consists of the following counties, formerly west central Illinois: Adams, Brown, Calhoun, Cass, Fulton, Greene, Hancock, Henderson, Knox, McDonough, Mercer, Morgan, Pike, Schuyler, Scott, and Warren counties.

All contacts must be made after June 28, 1980, to be valid. From the letter we received from the club, the award evidently is issued at no charge since no remittance was mentioned. Forward your list of verified contacts and a 9" x 12" SASE to the attention of AG9Y, c/o LEARC, 1224 Maple Avenue, Macomb IL 61455.



JUNIATA VALLEY

In March, the Juniata Valley Amateur Radio Club (JVARC) will be celebrating its 25th year as a bona fide club. In honor of the event, they will be operating a special event station. The club station is K3DNA, located in Lewistown PA (Mifflin county). Having started operation in January, their heavy operation is scheduled for the month of

March. The station will operate on different bands, CW and phone, according to the operators' wishes. One contact with any club member will entitle the operator to receive the club certificate.

VK1 ACHIEVEMENT AWARD

The A.C.T. Division of the Wireless Institute of Australia is proud to announce the creation of its newest award, the VK1 Achievement Award. This award has the aim of increasing interest in the VK1 prefix and in promoting Canberra and Australia internationally.

As there are only 300 VK1 licensees, the award will not be an easy one to achieve, particularly on some bands and modes.

The VK1 Award is available to licensed amateurs throughout the world. To qualify, stations within Australia must work 20 stations in VK1 land on HF and on VHF. Stations outside Australia must work a minimum of 10 VK1 stations for the HF segment of the award.

To apply, submit your list of contacts, including the GMT time and date worked, the band and mode of operation, and any reports or ciphers exchanged.

To be valid, all contacts must be made on or after January 1, 1978. Endorsements may be given at the time application is made. Five IRCs or $2.00 in Australian currency covers the cost of the award and should be sent to the Award Manager, c/o WIA, PO Box 46, Canberra A.C.T. 2600, Australia.

By the way, the VK1 Award is also made available to shortwave listening stations on a heard basis. QSL confirmation is required.

SNOWFLAKE MADNESS

The Michigan Technological University Amateur Radio Club and the Copper Country Radio Amateur Association announce a radio celebration of our Winter Carnival festivities in the northernmost part of Michigan's Upper Peninsula.

Tech's Winter Carnival is probably the most spectacular winter festival in America, with fantastic snow sculptures, dogsled races, lots of skiing, and other festive events.

In association with the Copper Country Chamber of Commerce, they are issuing a certificate to all amateurs who make contact with any ham in the Copper Country between 0000Z January 25 and 0000Z February 1. Only one contact is required for the certificate.

Suggested frequencies are: 3.975, 7.105, 7.285, and 21.385. Listen for CQ WINTER CARNIVAL.

Send your QSL along with 2 (two) 20-cent stamps to: Kevin J. Nietzke WD8DQR, 2005D Woodmar Drive, Houghton MI 49931.

WORKED BROWARD COUNTY CITIES

The Broward Amateur Radio Club, Inc., sponsors the new WBCC award available to licensed amateurs who submit proof of two-way contact as follows:

A) Residents of Broward, Colliers, Dade, Glades, Hendry, Lee, Martin, Monroe, or Palm Beach counties must work all 29 of the following cities listed below.

B) All other amateurs must work 15 of the 29 cities within Broward county.

To be valid, all contacts must be verified by at least two fellow amateurs and application must show all logbook information as well as the QTH of the station worked.

To apply, mail your application with $1.00 US funds and two first-class stamps (DX stations; send 10 IRCs) to: BARC Award Manager, WD4RAF, 1921 NW 41st Street, Oakland Park FL 33309.

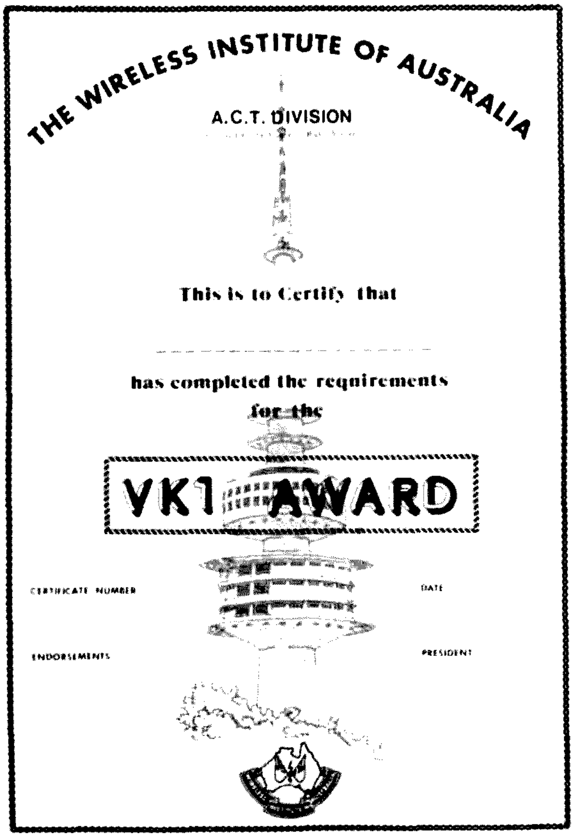
Qualifying city contacts include: Coconut Creek, Cooper City, Coral Springs, Dania, Davie, Deerfield Beach, Fort Lauderdale, Hacienda Village, Hallandale, Hillsboro Beach, Hollywood, Lauderdale-by-the-Sea, Lauderdale Lakes, Lauderhill, Lazy Lake, Lighthouse Point, Margate, Miramar, North Lauderdale, Oakland Park, Parkland, Pembroke Park, Pembroke Pines, Plantation, Pompano Beach, Sea Ranch Lakes, Sunrise, Tamarac, and Wilton Manors.

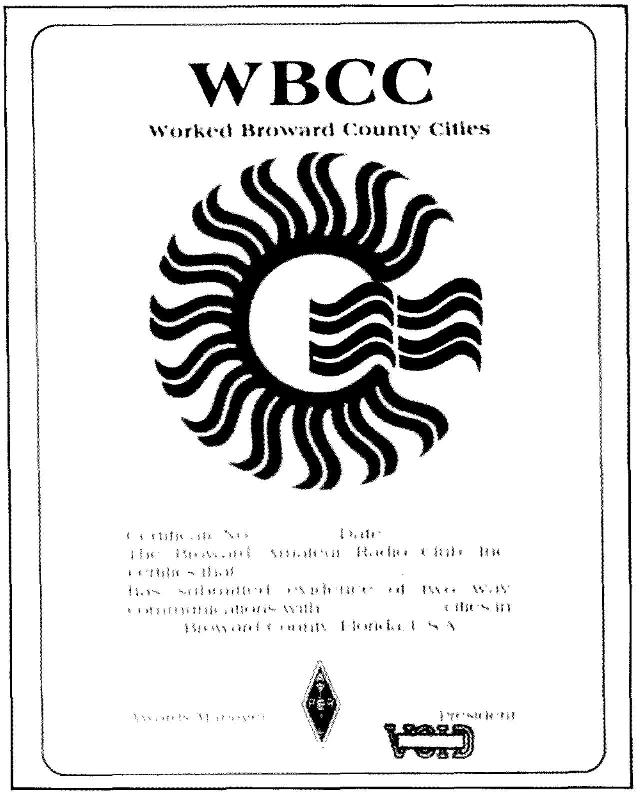
THE SOUTH EAST QUEENSLAND TELETYPE GROUP AWARD

This award is open to all transmitting and listening amateurs who gain award points in the following manner:

Australian amateurs must score 5 points and overseas amateurs must score 3 points.

(a) To qualify, a station must, where possible, copy the official station of the South East Queensland Teletype Group, VK4TTY, during a news broadcast and in the case of a transmitting amateur par-





ticipate in the callback (2 award points). A portion of the printout of the news broadcast together with the date, time, frequency, and broadcast number are to accompany the request for the award.

(b) Additionally, a transmitting amateur must work three member stations of the South East Queensland Teletype Group on RTTY (1 point each). Log extracts and/or printouts are to be included with the award application, and each member station may be counted only once towards the award.

(c) Listening amateurs should, in lieu of (b), forward log extracts and/or printouts of three contacts involving different member stations of the South East Queensland Teletype Group (1 point each).

Applicants for the award should forward the above information together with one dollar Australian or 5 IRCs to cover postage and printing costs to the Secretary, SEQTG, PO Box 274, Sunnybank, Queensland 4109, Australia.

WORKED ALL BERMUDA AWARD

The WAB Award is issued to amateurs throughout the world by the Radio Society of Bermuda. To qualify, applicants must submit proof of having worked a minimum of nine (9) parishes in Bermuda as listed below:

1. Sandys
2. Southampton
3. Warwick
4. Paget
5. Pembroke
6. Devonshire
7. Smith's
8. Hamilton
9. St. George's

The award is an antique map of Bermuda (20" x 23") suitably inscribed with the recipient's name and callsign and is signed by His Excellency, the Governor of Bermuda.

The award is not available to stations who worked Bermuda via mobile including maritime or aeronautical mobile. No band or mode endorsements are available. Only one mobile or portable from within Bermuda may be used in making claimed contacts on your application.

QSL cards are required as proof of contact and they must be sent to the awards manager with sufficient postage for their safe return. The Bermuda Award is issued free of charge! Submit your applications to: Award Manager, PO Box 275, Hamilton 5, Bermuda.

WORKED ALL DU AWARD

This award is available to all licensed amateurs who can show proof of having contacted at least one station from each of the call areas in the Republic of the Philippines (DU1 to DU9, except DU5).

Contacts may be made on any band or mode and special endorsements will be issued upon request for All-Phone, All-CW, Single-Band, or Five-Band accomplishments.

Contacts for the DU Award must be made on or after January 1, 1970. To apply, forward a list of contacts which have been verified by two officers of a radio organization. Your application must show all logbook information for each contact. Send the list and $4.00 US funds only (no IRCs please!) to: Edwin Zambrano DU1EFZ, PO Box AC-166, Quezon City 3001, Philippines.

All ASEAN Award
xx class

This award is given to 73 Magazine ***for establishing two way contacts with radio amateur stations in member countries of the ASEAN namely; Indonesia, Malaysia, Singapore, Thailand, and the Philippines.***

Awarded March 25, 1980 ***by the ORIENTAL DX CLUB, Quezon City, Philippines.***

Edwin Zambrano
President, ODXC

WORKED ALL ASEAN AWARD

The WAAA program requires the applicant to work other amateurs in the member countries of the Association of Southeast Asian Nations:

Work 5 Philippine contacts, 1 Malaysian contact, 2 Indonesian contacts, 1 in Thailand, and 1 station in Singapore.

Special endorsements will be given for All-Phone, All-CW, Single-Band, and Five-Band contacts.

Have your list of contacts verified by at least two radio club officials and be sure all contacts were made after January 1, 1970, to be valid. Forward appropriate logbook information in your application along with $4.00 US funds only (no IRCs) to the Award Manager: Edwin Zambrano DU1EFZ, PO Box AC-166, Quezon City 3001, Philippines.

KAHANER REPORT

Larry Kahaner WB2NEL
PO Box 39103
Washington DC 20016

By now you probably know that the FCC gave up in its attempt to rewrite the Amateur Radio Service rules. After spending thousands of dollars and consuming thousands of man-hours, the whole idea was thrown in the trash compactor.

We may never learn exactly what led to the shelving of the massive revamp nor will we ever realize any benefit from all that work. However, several FCC employees said privately what we all know intuitively about the project: It was just too big and too complicated to be completed.

You must admit the main premise was sound. Whenever a government agency wants to put its rules into plain English, we should all support it. In this case, it went a little too far. Opponents called the rewrite overly simplistic and said that many of the fine points of amateur radio were lost in the translation. They also claimed that the question and answer format—which worked so well for the rewritten CB rules—just didn't work for hams. Amateurs, they declared, were intelligent and took offense at the condescending stance of Q & A.

Moreover, the bulk of hams who responded to the petition

for rulemaking took umbrage at the very beginning of the rewrite proposal which dropped the famous reasons for amateurs' existence: promoting international goodwill, experimentation, and so on.

FCC officials told us that the rewrite contained many errors and mistakes—not just typos, but in substance as well. And although FCC proposals always contain errors, in this case it would have been just too much work to set things right. Normally, the commission works with opponents and proponents alike until the regulations are honed to where everyone can live with them. But for the ham rewrite, there was too much to do, too few staff to do it, and no funds available to keep the project alive.

On one hand, the FCC should be applauded for realizing that it would take resources beyond its means to complete the task and dropping it now before any more time and money was wasted. On the other hand, perhaps the commission should be scolded for even beginning a course of action that came under fire from hams at the onset. Even those in the commission expressed doubts as to whether it was necessary to rewrite the rules. It's certainly apparent that much of the impetus for change was political (see Kahaner Report, September, 1981). That should never be a reason for a government agency to do anything with taxpayers' money.

So, it seems that hams fought the measure and won. But the question arises—who lost?

OUR OWN CHANNEL 9

Paul Moratto KC5JK/6, from Universal City CA, mailed the FCC a petition for rulemaking requesting that it designate a particular 2m frequency to be used exclusively as an emergency and assistance channel. Paul also sent us the petition asking for our comment. Here goes.

It's a great idea, Paul, but it's not necessary. Hams don't need the FCC to set aside a special channel for emergency use. Hams can do it on their own.

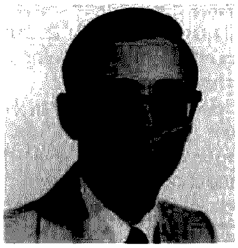
If hams can set up a national simplex channel (.52) and work out an entire repeater coordination scheme which only few hams don't adhere to, they can certainly decide for themselves if they want one frequency designated for emergency and assistance use only.

In his petition, Paul noted: "Various law enforcement officials have stated that the 2-meter amateur band is rarely monitored due to that fact that *no emergency frequency* has been officially designated exclusively for such communication." Frankly, Paul, I doubt that police departments would be willing to shell out bucks for a scanner that would pick up 2 meters or even buy crystals to place in scanners they may already own. Indeed, cops have enough to listen to without keeping an ear open on another frequency. If and when ham radio ranks reach that of CBers, maybe they'll listen—but right now it's not worth it.

Besides, even if they heard a distress call, they couldn't respond unless they were licensed hams. Many police are, but many aren't.

Any hams out there want to start work on a national emergency channel? Be my guest. Although I can't answer for the FCC, I'll bet they'll tell Paul exactly what I just told you: "If you want to do it, do it. You don't need us."

CONTESTS



Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

RSQB 7-MHZ CONTESTS

Phone Section
Starts: 1200 GMT February 6
Ends: 0900 GMT February 7
CW Section
Starts: 1200 GMT February 27
Ends: 0900 GMT February 28

Licensed radio amateurs and listeners throughout the world are invited to take part in this year's RSGB contests. Log and cover sheets may be obtained from RSGB Headquarters, 35 Doughty Street, London, England WC1N 2AE. Please include an SAE.

The general rules for RSGB HF contests, published in the January, 1982, issue of *Radio Communication*, will apply. Please note, however, that unmarked duplicate contacts will be penalized at 10 times the number of points claimed, and that logs containing in excess of 5 unmarked duplicate contacts will automatically be disqualified. Duplicate contacts should be included in your logs, marked as such, and without any claim for points.

Only RSGB members within the British Isles are eligible, while anyone else worldwide may enter. The only valid operating class is single operator.

EXCHANGE:

RS(T) plus serial number starting at 001.

FREQUENCIES:

Phone—7.04 to 7.1 MHz; CW—7.00 to 7.04 MHz.

SCORING:

Non-European stations with British Isles count 15 points per QSO. European stations with British Isles count 5 points per QSO. British Isles stations with European stations count 5 points per QSO, 15 points per non-European contact. British Isles stations may not work each other.

Multiplier for British Isles stations is the number of different countries worked—ARRL DXCC list applies. In addition, each VE, VK, W, ZL, and ZS call area counts as a country for this purpose.

Non-British Isles stations count one multiplier for each different British Isles prefix worked, maximum of 42. Please note that GB does not count!

Final score for all is QSO points times the total multiplier.

AWARDS:

The Thomas (G6QB) Memorial Trophy will be awarded to the leading British Isles entrant in the CW contest. Certificates will be sent to the entrants placed first, second, and third in the British Isles, European, and non-

Dec 11-12	ARRL 10-Meter Contest

European sections of each contest.

ENTRIES:

Log sheets should be headed: date, time (GMT), callsign of station worked, RS(T) and number sent, RS(T) and number received, if multiplier, and QSO points claimed. A summary sheet is required showing the countries or prefixes worked. Each log must be accompanied by the following declaration: "I declare that my station was operated in accordance with the rules of the contest and in accordance with the terms of my license." The declaration must be signed and dated. Closing date for receipt of logs is April 3rd for the phone section and April 24th for the CW section. Address entries to: RSGB HF Contests Committee, PO Box 73, Lichfield, Staffordshire WS13 6UJ England. In the case of any dispute, the ruling of the Council of the RSGB shall be final.

RECEIVING SECTION:

Rules are generally the same, as applicable. British Isles entrants should log only overseas stations in contact with British Isles stations and must record the report and serial number given by the overseas station and the time in GMT. European stations logged count 5 points; outside Europe, 15 points. No more than 20 QSOs made by any one British Isles station may be logged.

Overseas listeners should log British Isles stations and must record the reports and serial numbers given and the time in GMT. European listeners claim 5 points per QSO logged; others, 15. A bonus of 20 points may be claimed for each British Isles numerical prefix logged. GB prefixes do not count, and not more than 20 QSOs made by the same British station may be logged.

ARIZONA QSO PARTY

Starts: 2000 GMT February 6
Ends: 0800 GMT February 7

Sponsored by the Arizona Amateur Radio Club. Each station may be worked only once per band.

EXCHANGE:

RS(T) and state, province, country, or AZ county.

FREQUENCIES:

SSB—1815, 3895, 7230, 14280, 21365, 28560. CW—1805, 3560, 7060, 14060, 21060, 28060. Novice—3725, 7125, 21125, 28125.

SCORING:

Count 1 point per SSB QSO and 2 points for each CW or "exotic" mode QSO. AZ stations multiply QSO points by number of states, provinces, and countries. Others multiply QSO points by number of AZ counties. The AARC club station W7IO also counts as 1 multiplier for non-AZ stations. Anyone working all AZ counties and W7IO may double the multiplier.

AWARDS:

Certificates for the highest scoring station in each state, province, country, and AZ county.

ENTRIES:

Show each station worked, RST and exchange, plus time and frequency. Include a summary sheet of your scoring and other information. Include a large SASE for results. Mailing deadline is March 6th and should be addressed to: AARC, c/o Gary Kent KB7VE, 16647 N. 34th Avenue, Phoenix AZ 85023.

SOUTH CAROLINA QSO PARTY

Starts: 1800 GMT February 6
Ends: 2359 GMT February 7

The QSO party is again sponsored by the Colleton County Contestors. The same station may be worked on each band and mode, simplex only. SC mobile stations that change counties are considered new stations. Novice and Technician stations please sign /N or /T.

EXCHANGE:

RS(T) and state, province, country, or SC county.

SCORING:

Phone contacts are worth 2 QSO points, CW contacts are worth 3 points. The multiplier for SC stations is the number of states, provinces, and DX countries worked. Others multiply QSO points by the number of SC counties worked (46 maximum).

FREQUENCIES:

Phone—3895, 7230, 14280, 21365, 28560. CW—3560, 7060, 14060, 21060, 28060. Novice—3725, 7125, 21125, 28125.

AWARDS:

Certificates to top-scoring station in each SC county, state, province, and DX country. Novices and Technicians compete only with other Novices and Technicians.

ENTRIES:

Include a summary sheet with your entry showing scoring and other information. Indicate each new multiplier in your log as it is worked. Novice and Technician indicate class on your entry. Include a large SASE for results. Mailing deadline is March 5th; send to: Colleton County Contestors, c/o Elliott Farrell, Jr. WA4YUU, PO Box 994, Walterboro SC 29488.

QCWA QSO PARTY—CW

Starts: 0001 GMT February 13
Ends: 2400 GMT February 14

This is the 25th annual QCWA QSO party with separate weekends for CW and phone. Contacts with the same station on more than one band can be scored only once. Contacts made with "captive" stations, such as when operating in local nets, are not valid.

EXCHANGE:

QSO number, operator's name, and QCWA chapter identification (official number or name). Members not affiliated with a chapter should use "AL".

FREQUENCIES:

Any authorized amateur frequency is permissible. The following suggested frequencies have been selected to minimize interference to others: 3530-3560, 7030-7060, 14030-14060, 21040-21070, and 28040-29070. These are selected as a starting place. When pileups occur, don't be afraid to go either side of these frequencies.

SCORING:

Each contact made with another QCWA member will count as a single point. This year's contest has two multipliers. The first is the same as in years past: each chapter is a multiplier of one. The second is that DX sta-

QSL OF THE MONTH

Call us chauvinists, but the beautiful rendition of the New Hampshire countryside on this attractive card wins WB1GGQ his choice of any book in *73*'s Radio Bookshop.

Is your card a winner? To enter, place your card in an envelope along with your book selection and mail to *73 Magazine*, Pine Street, Peterborough NH 03458. Attention: QSL of the Month. To be eligible, your entry *must* be sent in an envelope and *must* be accompanied by your book selection.

tions are a multiplier of two. DX stations are defined as Europe, Africa, South America, Asia, and Oceania—the same as for WAC of ARRL. Contacts within your own country count only as a chapter multiplier. Final score is then the total QSO points times the sum of the number of chapters and DX stations worked.

AWARDS:

Plaques for the top phone and top CW scorers. Certificates will be given for the 2nd through 5th runners-up in both the phone and CW Parties. Standings and scores will be published in the *QCWA News*, issue of summer, 1982.

ENTRIES:

Logs should include the following information: time (GMT), call, QSO numbers, name, chapter number or name, state or country. It is the responsibility of each contestant to provide a legible log, no carbon copies, and to list all claimed contacts. The total contacts for each page will be recorded at the bottom of each page. The total contacts for the Party should be recorded at the top right of the first page of the log. Log sheets will not be returned. Make sure you have correct postage when you mail your logs. Send logs no later than March 31st to: Pine Tree Chapter 134, Glenn Baxter K1MAN, Long Pond Lodge, Belgrade Lakes ME 04918. Separate logs and scores must be submitted for the CW and phone parties.

Work as many QCWA members as possible and apply for the several special QCWA certificates which you have qualified for in the QCWA Parties: Worked 50 States, Worked 60 Chapters, Worked 100 Members, and Worked 500 Members.

WAS SSTV CONTEST

Starts: 0900 EST February 13
Ends: 2100 EST February 14

Sponsored by amateur television's *A5 Magazine*. Use all authorized and recognized SSTV operating frequencies within the HF bands. Attempt to work as many SSTV operators from other states as possible during the 36-hour contest period. The emphasis is on quality, not just quantity.

SCORING:

Count 25 points per contact with 10 bonus points awarded for live exchanges of "mugshots," color two-way contacts, or 256 or 128 (1/2-speed) mode transmissions. Add 100 points for each new state listed. Alaska and Hawaii contacts count a bonus factor of 500 points!

EXCHANGE:

Station calls and signal reports must be exchanged in video format by either camera, keyboard, or light-pen generators.

AWARDS:

First-place winnner receives a 3-year subscription (or renewal) to *A5 Magazine*, a framed Specialized Communication Certificate, and his photo published on the front cover of the magazine. Second- and third-place winners receive 1-year subscriptions and certificates. All contestants will receive gold certificates with submitted logs.

ENTRIES:

Submit actual or copies of contest log sheets by no later than March 1st to Contest Manager, *A5 Magazine*, PO Box H, Lowden IA 52255. Official results will be published in the May/June issue of *A5 Magazine*. Those winners attending the Dayton, Ohio, Hamvention will be awarded certificates at the regular ATV Forum meetings.

CQ WORLDWIDE 160-METER CONTEST—SSB

Starts: 2200 GMT February 26
Ends: 1600 GMT February 28

EXCHANGE:

RS plus a three-digit contact number starting with 001. US stations include state and Canadians include province.

SCORING:

US and Canadian stations count 2 points per QSO with other W/VE/VO stations; DX contacts are 10 points each.

DX stations count 2 points per QSO with stations in the same country and 5 points with stations in other countries. QSOs with W/VE/VO stations are 10 points each.

All stations count one multiplier point for each US state, VE province, and DX country. KH6 and KL7 are considered DX. Final score is total QSO points times the sum of multipliers.

AWARDS:

Certificates to the top scorers in each state, VE province, and DX country. Additional awards if the scores or returns warrant.

Two plaques are being awarded by the West Gulf ARC, both for single operators, one for the highest scoring US station and the other for Europe. The World Champion in the contest will receive the John Doremus WØAW Memorial Plaque from friends of WØAW. This plaque may be won only once by the same station in a three-year period.

PENALTIES:

Three additional contacts will be deleted from the score for each duplicate, false, or unverifiable contact removed from the log. A second multiplier will also be removed for each one lost by this action.

Violation of the rules and regulations pertaining to amateur radio in the country of the contestant, or the rules of the contest, or unsportmanship conduct, or taking credit for excessive duplicate contacts or multipliers will be deemed sufficient cause for disqualification. Disqualified stations or operators may be barred from competing in *CQ* contests for a period of up to three years.

ENTRIES:

Sample log and summary sheets may be obtained from *CQ* by sending a large SASE with sufficient postage to cover your request. It is not necessary to use the official form; you can use your own. Logs should have 40 contacts per page and show time in GMT, numbers sent and received, and separate columns for QSO points and multipliers. Indicate the multiplier only the first time it is worked.

Mailing deadline for SSB entries is March 31st. Logs can be sent directly to the 160 Contest Director, Don McClenon N4IN, 3075 Florida Avenue, Melbourne FL 32901 USA. Alternatively, they can be sent to *CQ*, 160-Meter Contest, 76 North Broadway, Hicksville NY 11801 USA.

NEWSLETTER CONTEST WINNER

Humor is a key part of this month's newsletter winner. *The National Hampoon*, published by the Cleveland-based South East Amateur Radio Club, is chock full of puns, good-natured put-downs, and inside jokes. Editor KA8KTR is not above poking fun at himself or the 33-year-old club. Besides being fun to read, *The National Hampoon* provides a deluge of information about what individual club members are doing. Don't let your club's members fall into the trap of not reading each newsletter. Try adding some life and humor; the readers will anxiously await the arrival of the next issue.

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 8

"This section shall not apply to receiving, divulging, publishing, or utilizing the contents of any radio communication which is transmitted by any station for the use of the general public; or which refers to ships, aircraft, vehicles, or persons in distress; or which is monitored pursuant to section 4(f)(6) and which is received, divulged, or used in any investigation or enforcement action by the Commission."

Explanation

This amendment conforms §605 to §4(f) to accommodate proposed language to permit use of volunteer monitors.

Here is another way that amateurs could help the Commission cut down on their costs. Not that they are spending a lot monitoring the ham bands these days anyway... and who needs 'em? But with the rules changed so that amateurs could set up a monitoring system, we would be able to clean up a lot of miseries which are now plaguing our bands.

We have tens of thousands of retired hams and several thousand more handicapped hams, all with loads of time on their hands and an eagerness to be of value. Well, here is a service that these hams could provide which would be priceless to us. I've talked with the FCC commissioners about this and they seem to be enthusiastic about the concept. You see, not only could hams be organized to monitor the ham bands, but they could also assist the FCC monitors in watching over some of the non-amateur bands, too.

If we once started getting into this monitoring idea, it would not be long before innovative hams would start coming up with automatic band scanners and receivers which would be connected to microcomputers and would program themselves to listen for unrecognized transmissions. With digital receivers and frequency counters, it is only one more step to a system which will keep track of what signals are okay on what frequencies and spot the anomalies quickly so they can be identified.

Not only would this be of great help for digging out emergency signals fast, but it would be even better protection against illicit transmissions involved with spying and drug traffic and so on. Coded transmissions? We have some mighty sharp ham cryptographers who would love to have challenges like that.

Why should the government spend wads of money doing something which we not only could do but probably could do better, and which we would enjoy doing?

Yes, a ham monitoring system would take some organization, but it wouldn't be difficult to handle. Much of the work could be done over the air, with unknown signals spotted and triangulated via a ham net. And with hams everywhere, even the UHF channels could be watched over in every part of the country. This would raise hell with crooks using CB or HTs on commercial channels to coordinate crimes. There would be no safe frequency or place in the country for them. Pity.

FRIENDLY CLUBS

Several letters from readers have made mention of a situation which I've noticed in some clubs I've visited...a lack of friendliness. Oh, it isn't intentional... but it is a drag. I suggest that club officers take a good critical look at the way their club is working and start doing something about it.

When someone new comes to a club meeting he (or she!) should be met by members and introduced around. Each person should have an identification badge so newcomers will know to whom they are talking. Members of the club should be aware that it is their responsibility to go out of their way to be friendly with any newcomers... to talk with them... show them around. Have the glad hand out.

When the newcomer arrives, try to find out about him... his call, if licensed... or if he is not yet licensed and might be interested in coming to the club license classes... what bands he works... and so on. Then get up at the meeting and introduce the newcomer and tell about his background so the others will know him. Make a big deal out of the newcomer and he will be back. You won't be able to keep him away with a stick.

In case you haven't noticed it, darned few hams are outgoing. The gregarious ham is unusual. Most hams are loners who may do just fine on the air, but are afraid to talk on a one-to-one basis. You should recognize this and gear your club meetings to overcome this situation. If you have a table where they can show their new and exciting QSL cards... that's a conversation breaker. Another table where they can show something they've built is another winner. Perhaps a spot to show off newly-purchased ham gear... stuff that is just recently on the market. Everyone is always interested in new rigs and gadgets. Anything you can work up in ways to get members showing and telling will break the ice and help everyone have a good time... and it is a good time at meetings which will bring 'em back alive next month.

This isn't the time to get into the details on how to run a ham club, but I will just touch on some of the basics. Remember that when you are running a ham club you are in show business. You want to keep for the board of directors as much of the dull business aspect of the club as you can, letting the meetings be times when you are entertaining the members.

What is entertaining? Well, demonstrations of unusual modes of communications are winners. You probably have someone in the area who is working with slow scan and can knock the socks off the members with color slow scan. Or perhaps some members are into computerized RTTY communications. Anything on 10 GHz? Any new antennas popped up which can be shown on a blackboard and explained? Slides of a Dxpedition are great fun.

How much do the members know of what is going on in the 450-MHz band? How about 220 MHz? Anyone working with SSB on 2m? How about aurora DXing, meteor-scatter DXing, moonbounce?

Manufacturers will go a long way to show their products when they have something new. Keep your eye on the new products section of *73* and see what you can generate. They want to show their products and they also want to get feedback from your members on possible new products. They need both the sales and the input.

DEREGULATION

The interest in deregulation by the Commission got started back in 1974, triggered by the *en banc* hearing at which a group of amateurs testified as to the need for deregulation. This turned out to be a matter of doing the right thing at the right time... as the Commission was just at that time getting interested in the concept. The hearing made clear the need for deregulation of amateur radio, and the Commission started with our service, intending to use it as an example of what could be done.

The hearing, by the way, was in response to the then-new regulations on repeaters, which were particularly onerous. Lacking any initiative from the ARRL, I got representatives together from repeater groups all around the country to testify before the Commissioners. If anyone is interested, I have a tape of this historical confrontation. The ARRL refused to participate, putting the effort down as naive and useless. The result was the biggest change in our rules ever brought about.

Of considerable significance is a recent paper (August, 1981) from the FCC. This is a working paper on deregulating the personal and amateur radio services. The paper is quite candid... surprising in its frankness. There are some interesting concepts... "many... agree that the goals of expanding technical skills and manpower and advancing the radio art have fallen on hard times in recent years." It goes on, "If there is criticism of amateurs for not being technically more advanced, it could be misdirected. Perhaps one should place some of the responsibility on the regulations, not the licensees. Substantially more regulatory flexibility than

the service now has would be desirable."

Frankly, that's an understatement.

The other day, on my way down to Florida to give a talk to a group of accountants who are using TRS-80 systems, I stopped by Tufts Electronics in Hudson, New Hampshire. Chuck recently moved from down near Boston to tax-free New Hampshire, thus saving nearby Massachusetts hams a bundle on their purchases. The new Yaesu FT-208R HT had just arrived, so I bought one.

As I punched up the channels on the synthesizer, programming the unit to scan several local repeaters and a simplex channel or two, I got to thinking about the whole two-meter US vs. Japan situation. Having been in the 2m ham field for over 40 years, I remember how things got started.

The first FM rigs were converted commercial systems, mostly by Motorola and G.E.—monsters, dumped on us when the commercial two-way specs were changed, rendering tens of thousands of taxi and police transceivers obsolete. Then came a rig from I.C.E. (in Texas) which never got to first base... mostly because it didn't work very well. The next try was from Galaxy (Missouri). Though unstable and much too large, it sold reasonably well. The engineering design was dismal. Ed Clegg, who had been building VHF equipment for us for years, came up with one of the better FM rigs of the time, but by then some of the Japanese equipment was starting to arrive.

Icom was designing very nice equipment, and it was selling well. Unfortunately, the company was taken to the cleaners by a crooked Arizona importer/distributor. Nothing daunted, Mr. Inoue, the president of the firm, came to the US and shopped around for a new importer. He also asked a lot of questions about what kind of new equipment was wanted... and listened carefully to the answers. The result was the IC-230, the first synthesized ham rig. Before that, the best-selling rigs were from Standard and featured ever more crystal sockets. I got to where I had to have hundreds of crystals on hand to cope with all of the repeaters going on the air... and the many different rigs.

Mr. Inoue said that he would some day be able to put a synthesizer into an HT for us. Well, we knew it would happen, but it seemed like a dream. You know, there was a small outfit out near Buffalo, New York, which came up with a synthesizer early in the game, but they never really followed up on it. It started out as a club project and then changed into a business. I think if they'd played their advertising right they could have developed into a large business by now with perhaps $50 million in sales.

Another firm which had a crack at it and dropped the ball was Vanguard, down on Long Island. Andre developed a synthesizer to plug into the older rigs, but didn't take it the next step.

It isn't really fair to put down US firms for losing the ball on FM equipment... or any other ham gear for that matter. You see, the Japanese went right on by us in the number of licensed hams, so their firms had a great advantage. Not only did they have more hams, but their hams were much more enthusiastic and active than we were. Amateur radio really took hold in Japan when they got rid of the Morse code requirement. Clubs sprang up in high schools all over the country, and today they have double to triple the number of active hams that we have. Further, their spirit is almost unbelievable.

Have you even thought of going on a DXpedition? Well, the Japanese have organized DXpeditions where they have had about 400 active hams going along and getting on the air! When you read the Japanese club magazine you find that it is packed for dozens of pages a month with pictures of club activities and outings. We don't appear to have a single club in the US which even comes close to the enthusiasm which has spread through Japan... at least I'm not familiar with any. I've asked several times for pictures of any outstanding club activities for publication in *73*... nothing yet.

One of the facts of business is that the more of the product you make, the cheaper it is to manufacture. When you double the production of a piece of equipment, the cost of making it goes down 15-25%. So this bunch of eager buyers in Japan has done two things to the ham equipment market. First, their enthusiasm has encouraged the Japanese firms to keep up a continuing development of new equipment. The volume of sales has forced American firms out of the market because the Japanese equipment has been both better and cheaper in most instances.

Where the shoe really begins to hurt is that we are now seeing the results of the over 500,000 Japanese hams and their enthusiasm. These chaps have now gone from high school through college, on into industry, and are wiping out the American consumer electronics industry. Their rate of graduation of engineers, technicians, and scientists has zoomed past ours.

In this respect, amateur radio has let America down. If you stop and think about it, most technical career people get started in their teens. By stopping the growth of amateur radio in 1963, with little since then, we have managed to kill off virtually a whole generation of technical people. Unless a person gets interested in electronics in high school, there is little reason for him to go into electronics as a career. So now we have a bunch of philosophy and liberal arts majors wandering around looking for work... while our electronics industry is getting wiped out by Japan.

There really isn't much we can do about the situation right now. We will be outgunned in technicians for some time to come. If we are going to get back into the driver's seat, we are going to have to figure out some way to get a whole generation of teenagers interested in technical careers. That's quite a challenge.

In the meanwhile, as I go further and further into the instruction book for the 208, I wonder what next in HTs. With the LCD display of the frequency, the 208 should have a substantially longer battery life than the 207. I like the scanning system... just what I've wanted for years, wherein it scans, stops on a busy channel for a few seconds, and then continues scanning. You can set it up for a priority channel... for instance, I generally monitor 147.540 for simplex calls. They've even made the battery compartment so that you can open it without a coin.

I picked up a mailing piece at Tufts which was rather clever... and sad. The headline on it was, "Where have all the amateur radio stores gone?" Then there are drawings of eleven graves with headstones for the eleven Greater Boston ham stores which have gone out of the ham business (or just plain out of business) in recent months.

With the recent even further drop in new licensees... down around 35%... ham stores all around the country are folding. The ones that seem to be failing the most are those which had little slogans such as, never undersold... call for low, low prices... 20% off... and so on. You know, unless we do something about all this, amateur radio will soon be little more than a retirement playground for elderly hams.

I admit to getting a bit frustrated when I visit some ham clubs and find that many of the members... old-timers, of course... are prepared to resist any efforts to bring in new hams as much as they can. They don't want the QRM... and they don't much enjoy talking to young hams... and don't want them trying to join their club. They would like to raise the code speed to 50 wpm and have everyone coming in pass the Extra class license exam... and then get restricted to the CW bands for a few years. They like *QST*, not *73*. These chaps are turning amateur radio from a friendly fraternity into an old farternity.

Apropos of the mention of the 1963 debacle, I looked back over my editorials and found that I had indeed predicted at the time that one of the results of the proposed rules change would be the demise of a great many dealers... and manufacturers. About 75% of the ham dealers

WARNING

Due to numerous complaints received from readers who have dealt with Electronic Specialties, Inc., of Miami, Florida, we have discontinued their advertisements and urge all readers to use caution when dealing with this firm.

went out of the ham business as a result . . . and most of the manufacturers. It's interesting to see the old ads for Hammarlund, Hallicrafters, National, Johnston, Squires-Sanders, Central Electronics, Lakeshore, Multi-Elmac, United Transformer, Stancor, Bud, Gonset, Polytronics, and so on. It sure wiped 'em out.

The 208 is a great rig . . . but it is not a breakthrough into anything really new. If we're going to get amateur radio pepped up, we have to get into the 80s and digital communications techniques. We really have nothing new to be excited about. FM is a bore for most of us . . . and heck, DX has been around for a lifetime. What have we that is really new and fun? We need something to get our juices flowing.

What have you got?

HAM WATCH REPAIR

Eventually, those Casio C-80 and C-90 watches run out of battery and need to get a battery refill. The replacement of the batteries isn't a really big deal . . . you can probably do it. Or, of course, you can fire it back to Casio for their $10 repair charge. Many jewelers are afraid of digital watches and claim they can't fix them. Tsk.

You can run into a problem with the Casio watches in that they often do not start when you replace the batteries. You have to short out the battery cover and a nearby metallic dot marked "AC" with a wire, tweezers, or even a paper clip to get the watch to start again. Jewelers have gotten instructions on this, but often just don't want to be bothered . . . or didn't read the instructions.

The C-80 and C-90 Casio watches, which I've written about before, are the ones which did the most to put both Texas Instruments and Commodore out of the watch business. Casio came out with a $50 watch which knocked the socks off everything else on the market. More and more of us around the magazine are wearing the C-90, beeping away every hour in unison.

My thanks to WB9OJD for the battery information on the watch.

GETTING RICH

Firms which are publicly held have a problem that privately owned firms don't have to worry about: making ever more money to keep the stock prices high.

This came to mind when I got a letter the other day . . . and not the first one . . . saying that the reason I want ham growth is so that I can make more money from *73 Magazine*. Let's take a good look at that cop-out.

First point. If I *were* interested in money, spending time on trying to get amateur radio growing would be one of the last ways I would invest my time. The real money today is in microcomputers, and the maximum return for hours spent is obviously in that field. Every time I start a new computer magazine, I generate a couple of million dollars more cash flow for us and bring employment to a bunch more people. I also help the microcomputer field to grow by virtue of the communications I bring about.

No, from a business point of view, I could care less whether amateur radio grows or not. If I were to fold up *73 Magazine*, we'd make more money using the people and facilities for the much, much more profitable computer publications. But I'd miss a lot of fun . . . and amateur radio would lose a lot of articles and enthusiasm.

Point Two. Even if we got into a great growth pattern and *73 Magazine* started to make a huge profit, the money would go toward my real goals, not to me. My goals are to provide education through my publications and through any other media available. If I had a million to spare right now, I would quickly put it into the development of Hawthorne-Green Institute, a college to teach electronics, communications, and computing.

I seriously doubt if many readers spend much less on themselves than I do. I do have to buy clothes so I look well, even if I begrudge the expense. That's part of being in business. My entire life revolves around the business. I grab breakfast at my desk, have a business lunch almost every day . . . or else I eat an apple and cheese at my desk. Dinners are often with advertisers, at ham clubs, computer shows, or on trips to visit manufacturers. I don't think my wife and I get together to eat dinner at home ten days a year. She, too, is wrapped up in our business, and we share a two-room apartment in the old house that is our headquarters building.

I'm serious about trying to get American technology back into the lead and I think I have the key to this. If you were in my shoes, wouldn't you feel that was a worthy goal? Further, I think it is a goal I can achieve.

Probably the "richest" time of my life was back in the mid-50s when I was the editor of *CQ* and also the president of a small hi-fi manufacturing firm. I made a big $15,000 at that time, which is a whole lot more than I'm making now in today's dollarettes. I was able to support a home, family, a seaplane, an Arabian horse, a small yacht, and two Porsches. One of the things which I learned was that toys like those own you, not the other way around. The horse had to be exercised every day . . . and trained. The Porsches needed constant service, most of which had to be self-provided. The damned yacht had to be scraped and painted every year or so, the engine worked on, and so on. The plane? You have no idea of misery until you own your own plane. It cost more per year to own and run than any two of the other toys. It was fun and I'm glad I did it, but I'm all over wanting yachts and planes.

Money has value only for what it can do towards my goals. If I can generate more, I can do more . . . and there is far more satisfaction in that than having a pocketful of hundred-dollar bills . . . or a bankful.

I have this dream of being able to help get amateur radio into more countries . . . as a way of helping those countries to grow. Countries have a desperate need for electronics and communications experts . . . technicians, engineers, and scientists. The best way, by far, for getting these needed people is via infection of teenagers with the virus of electronics . . . and that means amateur radio. It works!

If the United States is going to stay on top over the next generation or two, we need to invest in technical people. I'm working on that via my push to get amateur radio and computer clubs into every high school in the country. I'm also working on it via my Hawthorne-Green Institute concept . . . a college which is geared to the 1980s and 90s . . . one which will feature high-speed concentrated education in both technical matters and business. My aim is to provide the education which will bring us tens of thousands of entrepreneurs, all with electronics and computer backgrounds. Let's see *any* country get ahead of us then!

So, when someone puts me down as looking to make money, agree with them . . . and point out that so far I have a good record of investing that money for the benefit of amateur radio and computing . . . and, I hope you'll agree . . . for our country.

My ideas on how a college should be are spreading. I'm getting calls and visits from educators who are interested in the plan and who see it as a way to guide their schools into solvency in the next few years. With many private colleges failing, some radical change is needed. My talks on the subject in Brazil and South Africa brought great interest, with invites to come back and get together with government officials to further pursue the idea.

No, if I was into a personal fortune, one of the first things I would do would be to stop writing editorials, which I'm sure would immediately increase our circulation by about 50%. The next would be to stop my crusades, such as the very costly one twenty years ago to sell sideband to the readers—who hated it and felt that AM was the *only* way to go. Or the effort in 1969 to get amateurs interested in a little-known mode: NFM and repeaters. While I published hundreds upon hundreds of articles on repeaters and NFM, organized FM symposiums, put out a repeater bulletin, and dozens of books . . . the readers revolted, with about 20,000 dropping the magazine in disgust. Oh, most of 'em came back, sending me notes saying that, golly, I'd been right, sorry about that. But it was rough going for several years.

Not having a house or "family life" to take up my time, and not having a yacht, plane, horses, and dogs, I have the time to read so that I can keep up on computer technology . . . time to keep dozens of business projects going . . to personally use computers, video cameras . . . to go skiing occasionally, to travel . . . and even get on the air more than you might think. I have the time to write my editorials and even articles for other maga-

zines. I can get to Florida to give a talk on computers to an accounting group (expenses paid), to participate in a workshop on how to start special interest magazines (at the Folio show in New York). . . to get to South Africa and address data processing professionals on the impact of microcomputers. . .and so on. I do have to give up some things which are important to most people in order to do what I enjoy. . . pursuing my goal of education for as many people as possible.

It doesn't take money to do many of the things I do—just time management. I was able to set the 10.5-GHz record for states worked with borrowed equipment because I was willing to go up a damned mountain at all hours of the day and night for skeds. . .freezing my galuccis off.

Of course, if I get a lot of static about getting rich, I can always find some sucker to buy me out and go for a twenty-year sail around the world, charging $50 a contact to the Honor Roll hams, and live like a king. An enterprising ham can make $50,000 a year or more that way, as we have seen in the past.

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randallstown MD 21133

One of the fastest growing phases of RTTY these days, at least as evidenced by the questions I receive from readers of this column, is "computerized," or at least video, RTTY. More and more, the amateur is getting away from the old grease-monger of mechanical teleprinter and turning to one of the new microcomputer systems.

One of those systems hams appear to be turning to is the new Radio Shack TRS-80C(R), the so-called "Color Computer." Based on the powerful Motorola 6809 central processing unit, the TRS-80C appeals to the ham on many levels. Until recently, however, little was available in the way of RTTY software for this computer.

Now, Clay Abrams K6AEP, an author whose works are well-known to the readers of *73*, is offering some rather nice software for the TRS-80C at reasonable prices. Appealing to both the RTTY and SSTV enthusiast, Clay has put together some rather nice packages.

For the slow-scan television (SSTV) operator, Clay has three programs of varying degrees of capability. SSTV 7.2 converts the TRS-80C to an SSTV keyboard for sending frames of five lines each consisting of six characters. The next step up is SSTV 7.3, which expands the previous system to include an SSTV keyboard, color keyboard, video mixing, and joystick graphics. His ultimate system is SSTV 7.4, which allows gray-level picture transmission and reception, color-picture reception, tape-save ability, and many other features. The cost? SSTV 7.2 is only $20, and SSTV 7.3 and 7.4 are $30 each.

Not interested in SSTV, huh? Well, Clay has a few good RTTY programs, too! His bottom-line RTTY program, RTTY 7.01, allows RTTY transmission and reception in Murray and ASCII at all common rates. Three transmit buffers, an RY buffer, and a CW identifier are also provided. All this for $20. Clay's top-line program, RTTYCW, provides RTTY transceive, CW transceive, random code groups, split-screen display, multiple buffers, and tape saving. Requiring an external demodulator and CW interface, the program sells for the lofty sum of $30.

Interested? Drop Clay a line at Clay Abrams Software, 1758 Comstock Lane, San Jose CA 95124. Be sure to mention that you read about it in RTTY Loop, OK?

Interest in older machines is still around. Chuck Euola K8YPU, of Redford Township, Michigan, is using an Altair 680b. This M6800-based computer was introduced shortly after the Altair 8800, the "original" 8080 computer. Chuck is interested in receiving RTTY with his 680b, and wonders if some of the programs published to run with other 6800 systems will work. Other than changing the I/O address, the biggest problem you may have is with the slow speed of the 680b, as the clock runs at 500 kHz, roughly one half to one quarter of most other 6800 systems. However, you might try halving the constant in a delay loop, as calculated for a 1-MHz system, and then fine tuning as necessary. The program published in this column back in July, 1978, should work reasonably well.

Not everybody likes a computer, though. I have a letter here from Richard E. Christina, in Pahrump NV, who writes, "I need a transmitter strictly for RTTY. . .I would like about 200 Watts, 100% duty cycle, tubes, vfo. . .I do not desire to use a computer at this time."

Well, Richard, first of all, let's get our apples and oranges straight. The computer, if you use one, replaces the mechanical teleprinter, not the transmitter and receiver. No matter what method you use to display the RTTY signal, from an ancient Model 12 to a Whiz-Bang 6880 Micro-Term, you still need a transmitter, receiver (or transceiver), and antenna to get on the air.

Now, to the point of your question. A look through the back issues of *73* or any other amateur radio magazine or handbook will turn up many circuit descriptions for CW transmitters. Basically, that's all a RTTY transmitter is: a CW, i.e., continuous wave, transmitter in which the frequency determining element is modified by the digital RRY information. Adding that modification to the vfo, for example, involves a simple diode-capacitor combination, called a "shift pot," that we have covered in this column several times in the past few years.

As for the teleprinter itself, finding information on this machine or that can also take some doing. I have another letter here from K. D. Hardin KC5II, out in Albuquerque NM, who recently purchased a Teletype® Model 3320 and is looking for data on hooking it up. The 3320 is the "I/O" version of the Model 33, and is a very useful machine. This machine is designed to work in a 20-mA loop, and connection is via either a nine-position terminal strip or a twenty-pin plug, located on the back of the call control unit. This is the right rear corner of the machine, as you face it. Fig. 1 is a diagram of the nine-pin strip, terminal strip 151411, at the rear of the machine.

Unfortunately, not all Model 33s are alike, and minor differences in the call control unit can lead to major difficulties in hooking the machine up. Manuals are available from several sources; see the ads in this magazine for current availability.

I have a note here from Jeffrey A. Maass K8ND, who relates that RTTY DXers will have an opportunity to add Anguilla (VP2E) to their DX totals between February 23 and March 3, 1982. A group of contesters will travel to Anguilla to participate in the ARRL CW and SSB DX contests between February 15 and March 10,1982, and will be taking along a complete RTTY station. Amateurs using the calls VP2EV (QSL to K8ND), VP2EJ (QSL to WA8CZS), and VP2ED (QSL to

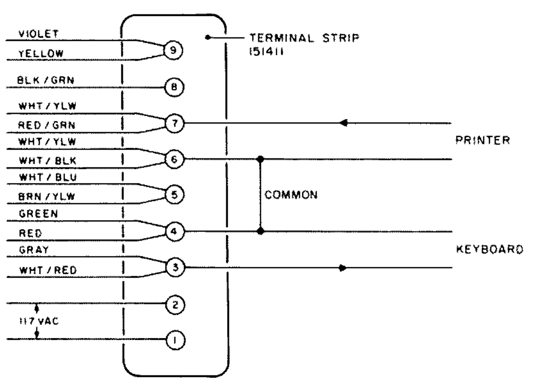

Fig. 1. Model 33 teletype hookup.

WB8VPA) will be operating in the time slot detailed above. Good luck!

By the way, the number of you interested in RTTY DXing does seem to be growing. Not only for two-way communications, but for looking for those rare press and commercial stations, too! Lt. Mike Anderson, with the U.S. Navy in Europe, is one of those folks. So I am happy to let you in on a little tip. A few months back, I mentioned Tom Harrington's book, *World Press Services Frequencies*, in this column. Available from the *73* Radio Bookshop at $5.95, this book contains listings of hundreds of commercial and governmental RTTY stations. One of the services promised by Tom was to keep buyers updated of recent "finds" and changes to the listing. Well, I have received his latest listing, and it is quite a gold mine for the individual interested in RTTY monitoring.

Well, this month brought Groundhog Day! Did the groundhog poke his head out of Baudot, see his shadow, and ASCII for six more weeks of winter? Who can say? (Murray can!) Find out here, in RTTY Loop!

NEW PRODUCTS

TEN-TEC 2-KW ANTENNA TUNER

Another first for Ten-Tec is a new 2-kW antenna tuner/swr bridge/power meter. The new tuner uses a reversible "L" configuration with a silver-plated roller inductor, high-voltage variable capacitor, and selectable fixed capacitors for greater versatility in impedance matching. The design automatically provides a low Q minimum loss path when properly adjusted. Power ratings are 2 kW PEP and 1 kW CW. Frequency range is 1.8-30 MHz. Model 229 matches conventional 50-Ohm unbalanced outputs of transceivers or linear amplifiers to a variety of balanced or unbalanced load impedances. Antennas such as dipoles, inverted "V"s, long random wires, windoms, beams, rhombics, mobile whips, Zepps, Hertz, and similar types can be matched. A built-in balun converts one antenna to a balanced configuration if desired.

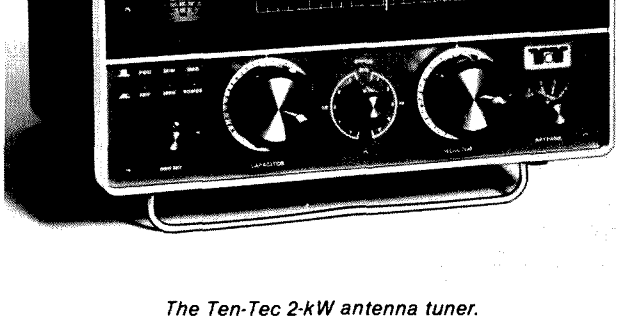
The built-in swr bridge and dual-range power meter indicates swr from 1:1 to 5:1 and power from 10 to 2000 Watts.

Front-panel controls are variable capacitor with spinner knob, roller inductor with spinner knob, 11-position bypass/hi-lo capacitor select switch, 4-position antenna selector switch, swr sensitivity, forward/reverse switch, 2000/200-Watt power range switch, and swr/power meter switch.

Rear panel includes coax input connector, four coax antenna connectors, three thumbscrew-type connectors for single wire and balanced line, ground connector, and 12-V dc input for dial lighting power.

Styling matches the Ten-Tec Omni transceiver and Hercules linear amplifier with black and bronze front panel with blackout lighting, satin-finish wraparound aluminum bezel, black textured vinyl-clad aluminum clamshell top, and bottom with fold-down stainless steel bail. Size: 6½" H × 12¾" W × 13½" D. Wt.: 9 lbs.

For full information, write *Ten-Tec, Highway 411 East, Sevierville TN 37862.*



The Ten-Tec 2-kW antenna tuner.

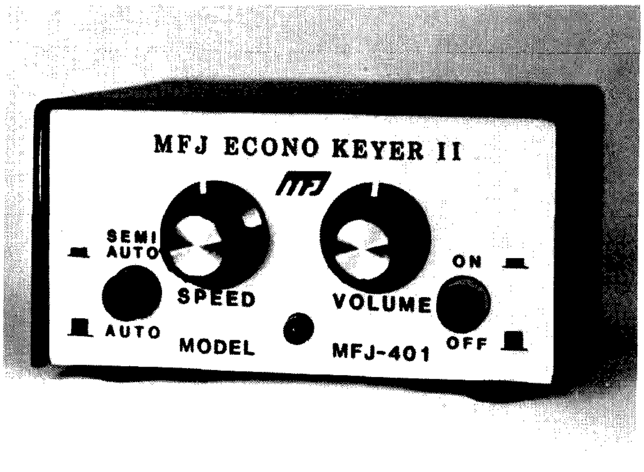
MFJ-401 AND MFJ-405 ECONO KEYER II

The MFJ-401 and MFJ-405 Econo Keyer II from MFJ Enterprises is a new full-feature economy keyer using the Curtis 8044 IC for reliability. The MFJ-401/405 *Econo Keyer II* has a much easier to use design and layout than the old Econo Keyer line. All controls are located on the front panel where they are easy to find and use.

The MFJ-401/405 Econo Keyer II has front-panel controls for both speed and volume. The on/off switch and auto/semi-auto switch is on the front panel. This switch lets you use the Econo Keyer II like a bug or it can be used to make tuning more convenient. A red LED indicates when the MFJ-401/405 Econo Keyer II is on. It may be used with an internal 9-volt battery or any source of 5-9 V dc. Circuitry is provided for both grid block and direct keying. This features lets the keyer work well with tube-type and solid-state rigs.

The MFJ-405 Econo Keyer II has a built-in clear lucite paddle and a jack on the back for an external iambic paddle. The MFJ-401 does not have a built-in paddle, but all other features are the same.

For more information, contact *MFJ Enterprises, Inc., PO Box 494, Mississippi State MS 39762.* Reader Service number 478.

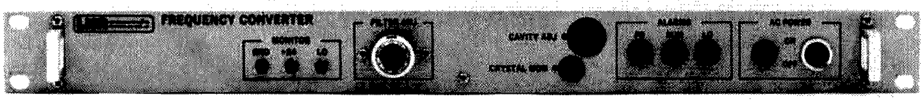


The MFJ-401 Econo Keyer II.

LNR DOWNCONVERTER FOR SATELLITE COMMUNICATIONS

The new Model DC4-E1 is a high-performance, low-profile rf to i-f converter especially designed for small terminal satellite Earth stations. Available in single thread and redundant configurations, this unit offers low phase noise and good frequency stability for digital and voice carriers, such as QPSK and FM-SCPC. The DC4-E1 is compact, measuring only 1-3/4" in height, and is designed for 19" rack mounting. Interfaces are coax connectors, so that the signal may be carried on low-cost coaxial cable. FET LNA power on the rf input connector is available as an option.

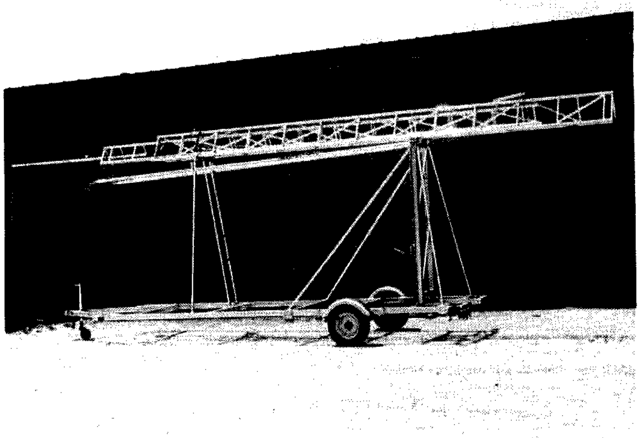
Low translation phase noise is ensured by an internal crystal-controlled phase-locked oscillator. Additionally, designed optimization ensures minimal intermodulation distortion. Each converter module is self-contained, including power supply. The unit is designed for unattended operation and has a remotable summary alarm and front-panel monitors for key operating parameters. LNR is a



The LNR frequency converter.

leading manufacturer of telecommunications equipment for satellite Earth stations.

For more information, please contact *LNR Communications, Inc., Marketing Department, 180 Marcus Blvd., Hauppauge NY 11787.* Reader Service number 480.



The Aluma Tower trailer.

NEW TOWER TRAILER

For those special situations that require communications tower mobility, Aluma Tower Co. introduces an all-steel trailer for transporting and erecting any Aluma Tower Co. aluminum or steel tower. Ideal for Field Day, civil defense, remote signal testing and many other situations, the tower/trailer combination is easily towed. Once in place, the tower is tilted up and cranked into position. The trailer acts as a secure base.

For more information, contact *Aluma Tower Co., 1639 Old Dixie Highway, Box 2806, Vero Beach FL 32960.* Reader Service number 482.

The HAL portable RTTY/CW terminal.

PORTABLE RTTY/CW TERMINAL

HAL Communications Corp. is pleased to announce the new CWR685A Telereader portable RTTY/CW terminal. Featuring compact size and 12-V dc operation, the CWR685A is just the thing for the traveling RTTY amateur who wants to "take it with him." A green phosphor 5" display is built into the small 12-3/4" × 11" × 5" main cabinet, as is a RTTY modem for 3 shifts, both "high" and "low" tones. The keyboard is separate and connects with a 3-foot cord to the main unit. Advanced features such as programmable HERE IS messages, type-ahead transmit buffer, and automatic transmit-receive control are included with the Telereader. The CWR685A can easily be slipped into a suitcase for a ham outing. In the home shack, the Telereader consumes little space and can be connected to an external monitor and parallel ASCII printer for even more versatility.

For more information, contact *HAL Communications Corp., Box 365, Urbana IL 61801.* Reader Service number 479.

SUPERCW

Frontier Enterprises has introduced SUPERCW, a computer-aided instruction program for the TRS-80 Model I or III microcomputer. Sound and graphics are combined to teach the user International Morse Code. By progressively increasing the copy speed, SUPERCW brings the user to 20 words per minute in as little as 72 hours of practice.

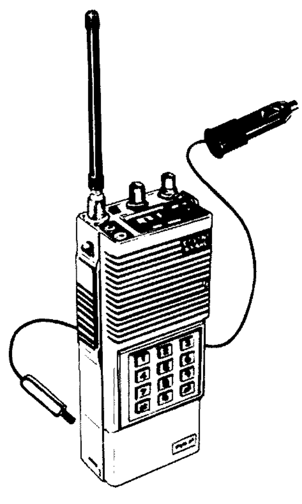
The disk-based SUPERCW package requires a 32K, 1-disk system. Features include random or plain text practice, sample testing, and provision for multiple users. For more information, contact *Frontier Enterprises, 3511 Gallows Road, Falls Church VA 22047.* Reader Service number 483.

MOBILE HT CHARGER

Mobile amateurs can operate and recharge their hand-held radios anytime with the new HT Power-Charger™ from Valor Enterprises. They simply insert the charger into the lighter socket and attach the mating plug to the radio. It will charge hand-held radios in less than an hour. The HT Power-Charger is not just a dropping resistor and diode, but a pair of transistors in a variable current regulator that is self-adjusting depending on the batteries' state of charge.

Mobile amateurs will appreciate the convenient package—all circuitry is enclosed in the plug with no box dangling on the cord. The HT Power-Charger features a built-in LED to indicate lighter socket function, with a five-foot connecting cable and plug to mate with the radio. There are six models designed to fit most popular amateur hand-held radios.

For more information, contact *Valor Enterprises, Inc., 185 W. Hamilton Street, West Milton OH 45383.* Reader Service number 481.



Valor Enterprises' mobile HT charger.

DEALER DIRECTORY

Phoenix AZ

The Southwest's most progressive communications company stocking Kenwood, Icom, Yaesu, MFJ, B&W, Astron, Larsen, Cushcraft, Hy-Gain, Bearcat, and more. Would like to serve you! **Power Communications Corp., 1640 West Camelback Rd., Phoenix AZ 85015, 241-Watt.**

Culver City CA

Jun's Electronics, 3919 Sepulveda Blvd., Culver City CA 90230, 390-8003. Trades 463-1886 San Diego. Call us for a low quote.

Fontana CA

Complete lines ICOM, DenTron, Ten-Tec, Mirage, Cubic, Lunar, over 4000 electronic products for hobbyist, technician, experimenter. Also CB radio, landmobile. **Fontana Electronics, 8628 Sierra Ave., Fontana CA 92335, 822-7710.**

San Diego CA

We buy and sell Surplus Army Navy Electronics, also Terminated Material. What do you want to sell? Write for catalogue. **Electronictown, Inc., 440-7th Avenue, PO Box 2048, San Diego CA 92112, 232-9379.**

San Jose CA
SAN FRANCISCO BAY AREA

Homebrewers' haven; tons of new and used Ham/Computer gear and components. Serving Hams since 1958. We specialize in ICOM, KLM, Mirage, Comptronix. We ship worldwide. **Tele-Com Electronics, 15460 Union Avenue, San Jose CA 95124, 377-4479.**

San Jose CA

Bay area's newest Amateur Radio store. New & used Amateur Radio sales & service. We feature Kenwood, ICOM, Azden, Yaesu, Ten-Tec, Santec & many more. **Shaver Radio, Inc., 1378 So. Bascom Ave., San Jose CA 95128, 998-1103.**

Miami FL

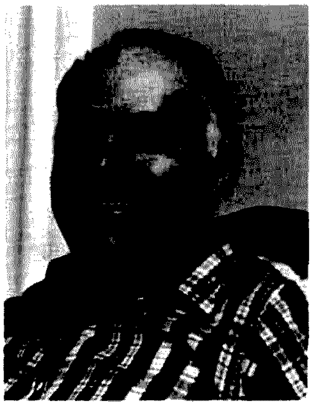
W2NSD/1
NEVER SAY DIE

editorial by Wayne Green



MORSE AND THE DEMISED PLAIN LANGUAGE RULES

The FCC would probably have been able to get amateurs to buy the proffered plain language rewrite of the ham regulations but for one major miscalculation. Sure, there were some aspects of the rewrite which were in need of repairs, but the one disastrous flaw was so enormous in the eyes of amateurs that it sank the whole project. This was the deletion of 97.1, the Basis and Purpose of amateur radio.

All amateurs, whether walking around with an HT on the hip monitoring the local repeater or adding to the mess on 20 meters with fruitless calls in the pileups, are proud of the fundamental reasons for the existence of our hobby...or service, as the government likes to call it. When the FCC tampered with those magic words, they brought us out of our corner fighting.

Well, let's take a look at the words...and the concepts involved. Let's think about them in terms of our own personal contribution to amateur radio and see how we measure up. Let's also mull over the place of Morse code in this realm.

97.1(a) bids us to provide a noncommercial communications service, particularly with respect to emergencies. Fine. Some of us do that on occasion. Others make a career out of it. Well, we don't need a half-million active message handlers either during or between emergencies. We do need enough traffic-handling training so that whatever amateurs happen to be selected for an emergency situation by chance know what to do efficiently.

There is a tendency to think of traffic handling in terms of the CW nets which pass around endless streams of make-work messages, racking up traffic-handling scores for listing in *QST*. If we are going to be more honest about this, we have to admit grudgingly that when the chips are down, the emergency communications for most situations are handled on phone via two meters and repeaters... something few amateurs have had any real emergency experience with. One of the results of this is a pathetically slow traffic flow, with high percentages of the time wasted in callsign exchanges, the endless repeating of words spelled out letter by letter, and the jamming of transmissions by operators unfamiliar with emergency traffic handling.

If you stop to think about it, we are years beyond the time when we should have established a nationwide automated traffic net on high-speed ASCII which would route and pass along messages without any operator being needed. The resistance, right from the beginning, of the traffic organizations to the use of RTTY has kept this part of our "service" about 30 years behind technology. A group of us developed and were using automated message-handling techniques in the late 1940s, only to find a fierce resistance from the national relay organization to any changes from CW.

For emergency purposes, where two meters is the optimum band for local communications, we need hand and mobile phone rigs, not Morse code. With all due respect, there are times when it is advantageous to have a working system which even a CBer can step in and use if needed. Trying to stick to code for such communications is featherbedding.

If we are ever going to set up any serious emergency traffic-handling system in this country...or the world (why think small?)...it is going to have to be up-to-date. This means that we are going to have to think in terms of digital electronics and microcomputers, with automatic message pickup and relaying and with error-correcting codes which will ensure 100% copy at all times.

Indeed, if we start working on the elements of such a system now, I believe that within five years amateur radio can have an emergency communications system of which we can be proud. Such a system, if it is to work when really needed, must be in everyday use. Only in this way can we encourage the investment in equipment and technology which is required ...an investment by amateurs, not the government.

You know, if the worst should happen, our country could well be up the creek if we don't have a comprehensive system. I'm talking about automatic polling of stations in a net by the net control, with all messages typed in on a pocket-sized computer. I'm talking about relaying via repeaters, via satellites (ham and commercial), and via low-band links over any desired distances.

One of the last things we need in an emergency is to have to depend on the handful of hams who are good sharp Morse code operators. You know as well as I that at least 90% of the hams today are not capable of copying code at a reasonable speed under emergency conditions. Who are we trying to fool?

So much for 97.1(a)...though I will be writing more about our responsibility to catch up with technology for traffic handling and emergency nets. Let's look at 97.1(b) now...which has to do with the amateur contributing to the advancement of the state of the radio art. Well, we've a good history of that, if you look back far enough. In recent times we have little of which to be proud. Admittedly a good part of the responsibility for this lies with the FCC's restrictive regulations and inflexibility. But that isn't the whole story by any means.

Let me ask this...where does Morse code fit in any picture of the advancement of the radio art? Other than harking back to the beginnings of radio communications...before radiotelephone was invented...code plays little part in modern communications. Advancing technology has to do these days with digital techniques, with satellites, with microwaves, with high-speed communications, and many other possible new modes of communications. Revering our roots is one thing,

CALL FOR ARTICLES

Are you a RTTY, SSTV, or fast-scan TV enthusiast? Share your knowledge and enthusiasm with the rest of us by writing an article about your favorite mode. We are planning several special issues for later this year, so get cracking. Send your submissions to: Editor, *73 Magazine*, Pine Street, Peterborough NH 03458.

$$ HOME-BREW CONTEST $$

You can win a cash prize and receive fame and fortune by being a published author, all for telling us about your latest home-brew project. See the rules on page 6 of the February, 1982, issue of *73* for the rest of the story.

but making a fetish of it is something else.

If we are going to live up to 97.1(b), it is about time that we shelved the code concept and encouraged amateurs to start building, experimenting, and pioneering new ideas. It is time we got behind the magazines pushing this concept. It is time we got these ideas into our clubs and discussed them.

I would love to print technical breakthrough articles as I did in past years. I still remember the Bill Ashby article on the Flying Nose Lock . . . the Costas articles on double sideband, years ahead of his time only because amateurs failed to take the bait and run with it . . . the parametric amplifier by Sam Harris, an invention which changed the long-range radar picture worldwide.

97.1(c) is a "rule" which is directed at the Commission, not at amateurs. Pity, for this is one of the most broken rules in our regulations. This one asks the FCC to encourage and improve the amateur service through rules which provide for the advancing of skills in both communications and the technical phases of the art. We've never had it so bad. If we had had any real national organization, it would have taken the FCC to court and sued in the name of the United States for several billion dollars . . . which is what has been lost due to the restrictive way the Commission has handled the amateur service . . . and totally ignored this rule.

Indeed, our country has lost many billions just as a result of the inept handling of the "incentive licensing" proposals of 1963. How much business has our country lost to Japan in television, radio, and other electronics equipment in the last few years? We are about one million engineers and technicians behind, today, as a result of that proposal—as I've beefed before.

Let's move on to 97.1(d) in our search for some ray of hope for a need for code. This one has to do with our providing a reservoir of trained operators, techni-

Photo A. Field Porta-Peater hookup with FT-227 and Tempo VHF-1. This Porta-Peater is housed in a minibox on a 19" rack panel (original prototype).

Emergency situations always seem to happen where there is limited repeater coverage available or limited HT range, or when no one's HT has a crystal frequency which matches anyone else's (sound familiar?). The Porta-Peater™ solves these problems and provides capability and versatility beyond any commercially-available repeater package—and for a lot less money.

The system is an audio-driven command and control module which takes any two rigs and converts them into a QRP, frequency-agile, VOX-driven repeater with CW IDer, hang, and cycle timers. All this with absolutely NO modifications to any of the radios. All connections are made via the available audio input and output jacks on the radios. You can run any mode, any band, cross band, etc. Do whatever your heart desires! You are limited only by your imagination and the FCC for Porta-Peater applications.

A complete Porta-Peater should run you less than $100 for all new parts including an enclosure (but no printed circuit board).

Photo A shows a Porta-Peater field repeater in action. Notice the simple installation. This one is set up on two meters.

Birth of Porta-Peater

The idea for Porta-Peater came from AC2A's desire to be able to erect an instant repeater at hamfests on a frequency fitting most of the HTs in use that day. Since one could never be sure who would be along on the day of a hamfest, there was no way of knowing whose rigs would be available to build into a temporary repeater. This meant no modifications could be made to anybody's unit. Also, we were too cheap to want to invest $600 in a fixed-frequency repeater for what basically was just playing around.

Photo B shows the first Porta-Peater. It was a simple control system with IDer capability but limited timer ability. It was set up at a local Philadelphia hamfest using a Tempo VHF One-Plus, a Yaesu FT-227R, and two separate Larsen 5/8-wavelength antennas about fifty feet apart (one on the ground, the other about 10 feet up). Both rigs were set to low-power output. Fantastic! Everybody liked it and used it. We switched frequencies, splits. You could do whatever you wanted, with limitations depending on what rigs you used, not the repeater control.

Passersby suggested using split band/mode, etc., and its application to emergency usage. This thing was really *more than* just a toy. It had the makings of being the basis for an instant emergency repeater system, with super possibilities. With the Porta-Peater, you could put a repeater on the air as fast as you could hook up two audio cables and two antennas.

Porta-Peater I was a hand-wired, non-reproducible model with diode matrix IDer. Definitely not the stuff articles are made of. It was ugly, but it did work and work well. Porta-Peater II had a nice PCB layout with a new PROM CW IDer. It looked good, worked lousy. Six months (part-time, with spurts of midnight-oil genius) were spent creating Porta-Peater III which looks good, works well, and is capable of being reproduced by other hams. Photos C and D show a boxed unit, and Photo E shows a rack-mount version.

Theory of Operation

The basic concept behind the Porta-Peater was the creation of a repeater by taking any two readily-available amateur radios. One rig acts strictly as a receiver and the other as a transmitter. Fig. 1 is a schematic representation. One rig (any band/mode) receives an incoming signal; it is taken off the external speaker jack and fed into the Porta-Peater. Here it is amplified, and the audio is used to trigger the other rig's transmitter (any band/mode) line via the Porta-Peater VOX. Incoming audio also starts the time-out timer. A separate internal timer controls the CW IDer cycle. Porta-Peater is an interface link between the audio output jack of one rig and the microphone jack of the other rig.

If you use two 2-meter rigs, a duplexer is not necessary since separate TX and RX antennas work quite well with about 40 or so feet between them at QRP levels. The quality of the particular rigs in use (front end specs) determines individual antenna-spacing requirements. Also, since the emergency usage of the Porta-Peater is based on the fact that you don't know in advance what bands on which you may be setting up a repeater (6, 2, 1-1/4, 3/4, etc.), a carload of duplexers in one's back seat generally is not appreciated by the family. Also, it ain't cheap!

The Porta-Peater would be extremely effective in hooking up a VHF link into a low-band rig command center via a repeater, with easy crossband communications. Since the system is VOX driven, you could create multiple-rig and repeater systems in any configuration needed. Just keep a supply of audio jumper cables handy.

Circuit Description

The Porta-Peater circuit is composed of six basic functions: a local mike amp, VOX amplifier, VOX trigger, reset timer, ID timer, and a selectable four-message PROM CW IDer. All circuit symbols are on Figs. 2 and 3. Audio from a receiver source is fed into an input transformer (T1), which provides a voltage transformation of 5-to-1 to drive the LM 3900 amp (section U1A), and the audio input of the transmitter. The LM3900 is a quad Norton current-mode amplifier. U1A and U1B form the VOX system. The VOX also can be triggered by closing the local PTT contact, which removes U1A pin 3 current bias and turns the VOX on. R2 and C1 form the hang-timer components for VOX hold-in.

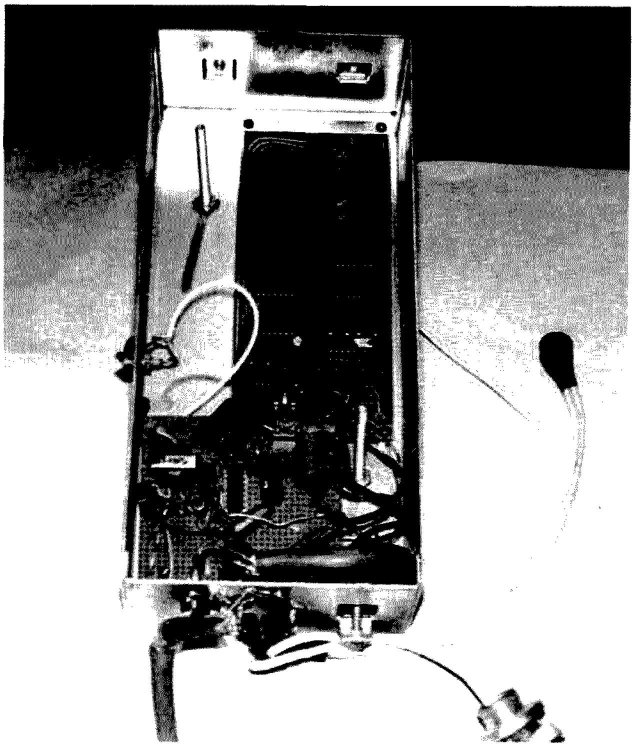

Photo B. Inside view of first unit from Photo A. CW IDer takes up most of box. Control system is in front.

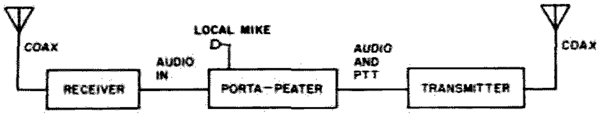

Fig. 1. System layout shows how simply a portable system can be constructed.

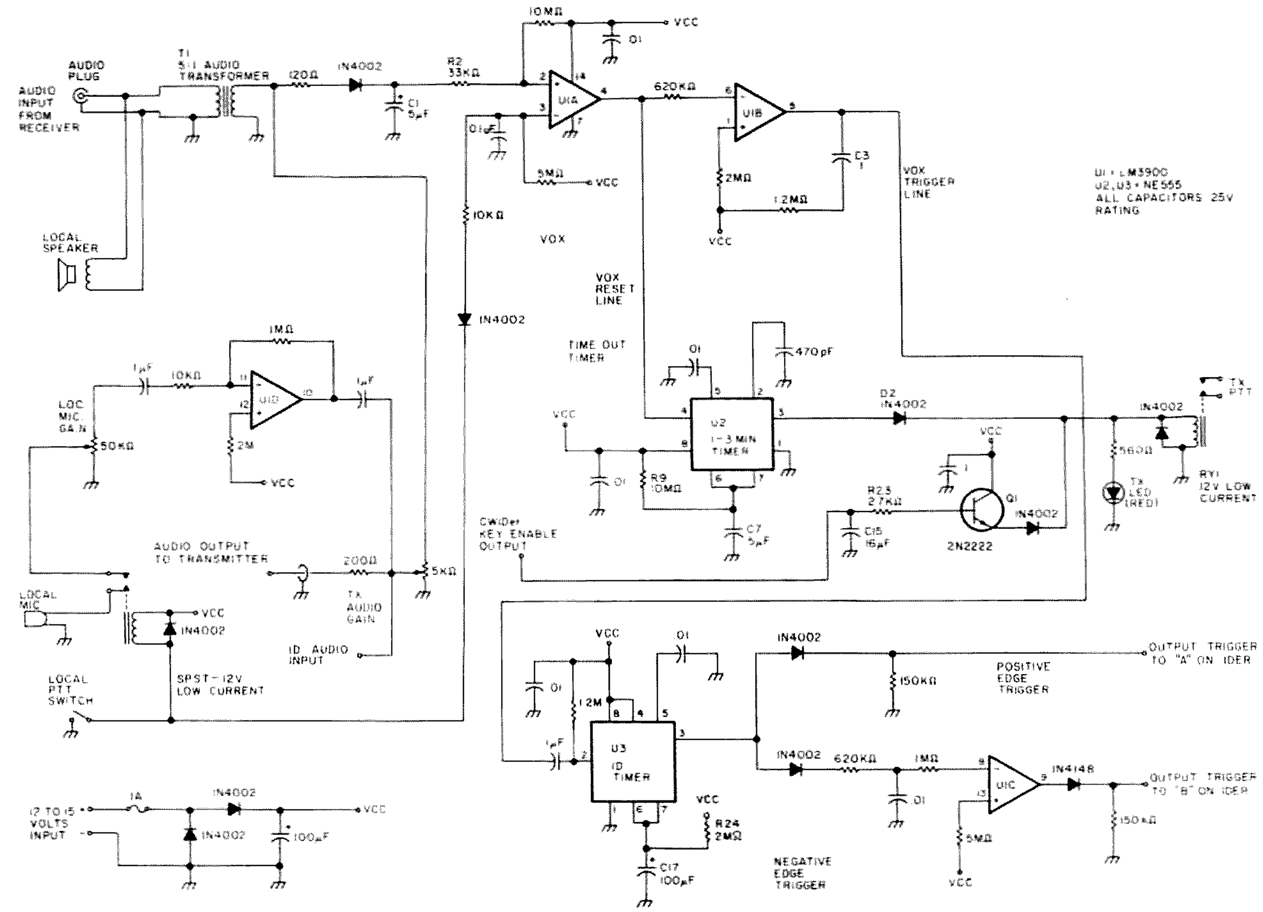

Fig. 2. Schematic of command and control logic for the Porta-Peater.

U1A output is normally low, which defeats the 555 timer, U2. The presence of an audio signal at U1A pin 2 shifts pin 4 to Vcc and enables the timer. U1B inverts the audio signal and provides a negative pulse through C3 and triggers U2 on, which is the 1-minute (adjustable via R9 and C7) time-out timer, and drives PTT relay RY1 on. Time-out timer U2 resets every time the VOX reset line goes low. D2 serves to isolate U2 from spikes due to RY1 operation.

Q1 is a relay driver driven by the CW ID source. The emitter follower is held reasonably high between ID pulses by R23 and C15. The 5-minute ID timer (adjustable via R24 and C17) is keyed by the VOX but is not reset by the VOX. When the 5-minute timer runs out, if

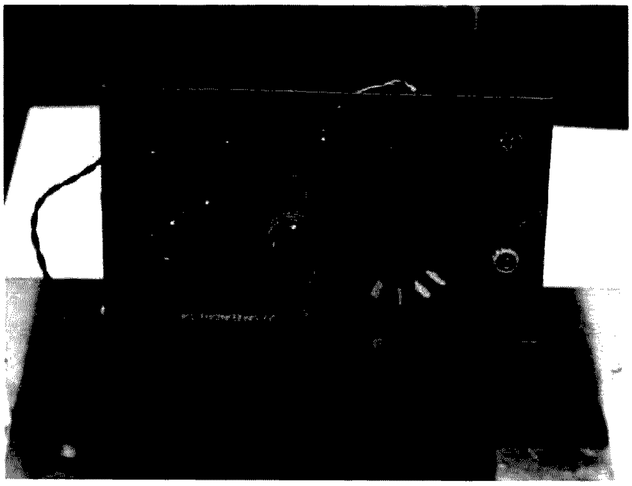

Photo C. Front view of the third version unit with four selectable IDs.

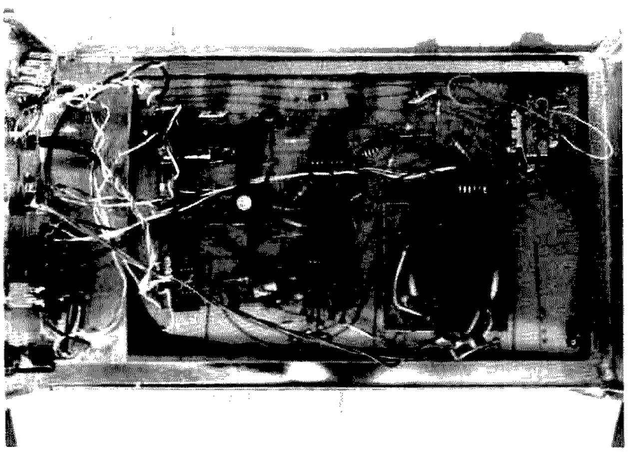

Photo D. Inside view of the same unit shown in Photo C.

the Porta-Peater is not in use, U1C inverts the falling pin 3 pulse and provides a positive trigger output to turn on the CW IDer, which in turn drives Q1 on and turns on the transmitter for the final ID as required by the FCC.

The CW IDer is based on an 82S126 PROM, which is a 4-by-256 device. In the PROM, 1 bit is a dit and space, 3 bits a dash and letter space, and 7 bits a word space. The message is played back from memory by being sequentially addressed by the 4020 binary counter driven by one half of the 4011 in an oscillator mode. The particular 256-bit message grouping is selected by switching pins 12, 11, 10, or 9 of the 82S126. The output is combined with the clock signal in the remaining NAND of 4011 and available as a tone at the 10k pot. The output is adjusted to provide drive as needed.

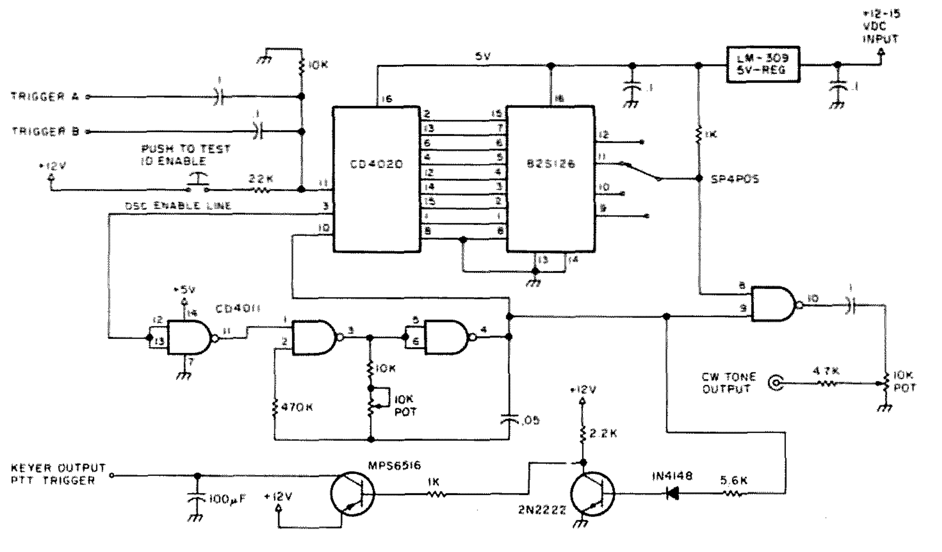

Fig. 3. Schematic of CW IDer. Any IDer can be used with the basic system shown in Fig. 2.

Burning the messages into the PROM is not particularly easy unless you are equipped to do it properly. If you don't have a PROM programmer, it is best to buy a chip and have the supplier burn the memory. Any IDer will work with the Porta-Peater (i.e., diode matrix, or other PROM/ROM types) as long as an audio output signal and an external trigger input line are available. The original model used a VHF Engineering kit. Alternatively, you can build the system without any IDer at all and use voice ID.

The circuit as designed uses an isolated single-pole relay for switching. Depending on your radio, you may have to use an SPDT relay for electronics-switched radios to move 12 volts from the RX to TX enable lines. For relay-switched rigs, simply use the SPST to complete the relay circuit in your radio.

Construction

The latest version of the Porta-Peater is mounted on two printed circuit boards, a mother and a daughter board. The mother board is shown in Photo F. Most of our units used a hand-wired panel instead of a daughter board. The mother board contains all of the command, control, and ID functions. All signal I/O, ground, and power buses are brought out to a standard 0.156-inch, 22-pin edge card connector. The daughter board interfaces to the mother board via the connector, or you can handwire the two boards together.

The daughter board has the TX LED, audio input jack, PTT output jack, local mike jack, ID-message-select switch, and ID-test switch mounted on it. This approach makes for a design that can be put in various enclosures easily without rewiring. Photo F shows how jumper wires were used instead of a daughter board.

The selection of enclosure is a matter of personal choice. The only requirement is that it be reasonably rf tight. The last thing you need is rf floating around inside an audio-frequency-control system.

Cable Assembly

Two interface cables are required to use the system. One is a shielded audio line and the other is a four-conductor microphone push-to-talk line. Since normally you will use the Porta-Peater physically close to the two rigs forming the repeater pair, a short convenient length is all that is needed. Two-foot lengths are a good starting point.

Most newer transceivers use subminiature jacks for external speakers. The jack

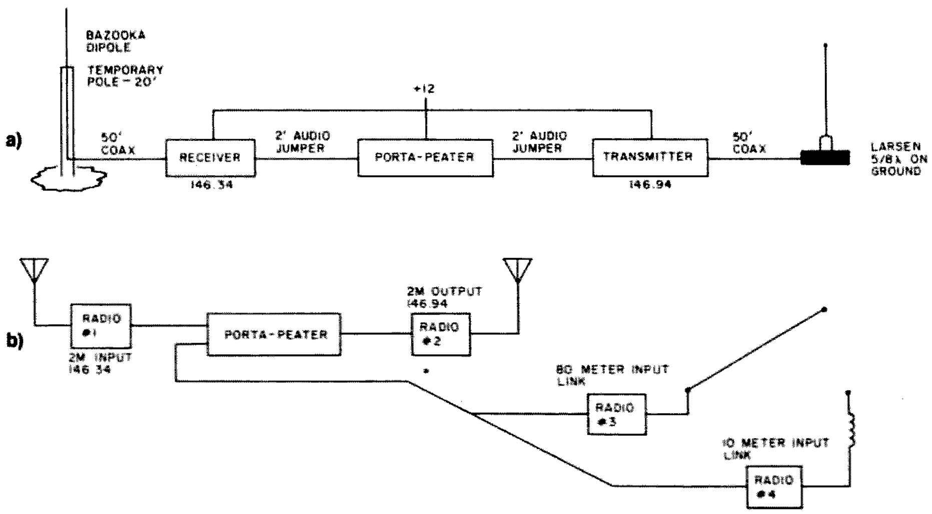

Fig. 5. Layout (a) shows a typical 2m hookup, and (b) a 3-band input command center. All inputs show up on 146.94 out. Mode has no effect on the system (i.e., CW, SSB, FM).

on the audio input of the Porta-Peater is also subminiature. Therefore, make up or buy a shielded jumper with subminiature connectors at both ends. In order to cover more possibilities, you might want to purchase several connector converters to change the subminiatures to PL-55 or whatever you have. Remember, the cable must be shielded.

The Porta-Peater uses a standard 4-pin, screw-on microphone plug. Again, most new rigs use this type, also. It is important that you make up this cable with the proper pin assignments. If you know in advance with which rigs you most likely will be using the Porta-Peater, you can make up a couple of dedicated jumpers. Alternatively, a small minibox can be made with a terminal block inside and the proper jumper assignments made for the rig to be used. Fig. 6 shows a possible design. This approach permits fast and easy field changes. Again, use only shielded cable.

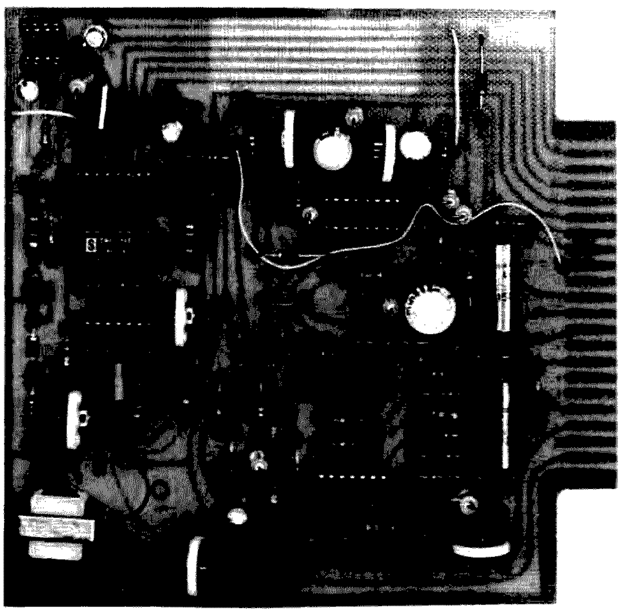

Photo F. Populated printed circuit board with externally mounted IDer on right side. Final version was all on one board.

Circuit Assembly

Figs. 2 and 3 show the entire circuit for Porta-Peater III. PCB construction is recommended but not required. (A commercially-manufactured PCB is available for purchase; write WA2BHB or AC2A for information.) Any type of perfboard assembly is fine. Layout is not critical except for isolating the inputs and outputs of the high-gain LM3900. Parts substitutions can be made except for the low-leakage tantalum capacitors. These must be used where specified because otherwise the circuit performance will be degraded or it will not work at all.

Alignment and Adjustment

The adjustments of the audio gains on the Porta-Peater are set to the particular rigs it is connected to. Simply hook up two rigs as per the schematic in Figs. 1, 2, and 3. Apply power and adjust for best audio. Select your ID message, push to test, and you are finished. If things don't seem all peaches and cream, perform troubleshooting procedures.

Troubleshooting

If your unit does not function, use the fail/cure list in Fig. 4 and you should be able to home in on the problem in a few minutes. (This list assumes that you have previously looked for broken connections and bad solder joints and taken corrective action.) Before taking apart your unit, be sure you have checked and tried the full range of adjustments on all the pots for gain, output, and oscillation on the Porta-Peater.

Field Hookup

In a field installation, all that is needed is two rigs and a 12-volt source to set up a Porta-Peater repeater. Remember, you can configure any setup you wish by proper interconnection of the audio output and microphone PTT lines to the rigs in use. The Porta-Peater gives you the capability to set up a reasonably sophisticated communications network based simply on whatever random collection of amateur rigs happens to be available in any emergency situation. Fig. 5 shows some configuration possibilities.

For a typical 2-meter QRP repeater setup, follow these instructions:

1) Select the rig to act as a receiver.

2) Set the desired input frequency on this unit.

3) Run a jumper from the external-speaker jack of the receiver rig to the audio-input jack of the Porta-Peater.

4) Connect the PTT-microphone-output jack of the Porta-Peater to the microphone-input jack of the rig selected as the transmitter. Make sure all ground audio and switching lines are wired correctly; otherwise the system will not work or could damage the

units. Set up the transmitter frequency.

5) Apply +12 volts to all units.

6) Set the receiver squelch to the desired trigger level.

7) Adjust the receiver volume control (when receiving a signal) to a level which doesn't overdrive the Porta-Peater and distort the transmitter signal (a quick on-the-air check is best; monitor with an HT).

8) Turn the volume on the transmitter rig to low or off (volume, not power).

9) Locate antennas for minimum interference and overload. (See Antenna Setup Hints.)

10) Operate and enjoy!

Antenna Setup Hints

If you want frequency agility and you are not using a duplexer, all of your isolation comes from antenna separation. Our standard setup uses two 50-foot lengths of RG-8 coax and a pair of 10-foot poles. One pole is aluminum, the other is bamboo. The two poles are lashed together, with the bamboo on top. A vertical dipole is made from the RG-8 by turning down the braid 19 inches leaving the insulated center conductor as is. This forms a bazooka dipole for one antenna; the Larsen 5/8 wavelength is used for the other. A 1/4 wavelength can be used, but in either case, ground-level mounting is employed.

In our field trials, it did not seem to matter which antenna was used for receiving or transmitting. You probably will want to try the different combinations for yourself in case there is some incremental improvement for a particular location. Under any circumstances, the two antennas should be separated as far as possible or until desensitization ceases. I often bring up the Porta-Peater before laying out the antennas, then, while the rig is madly squealing, walk the ground-level antenna away until the squealing stops.

In severe space-limitation situations, we sometimes put an attenuator in the receiver transmission line and eliminate desensitization by lessening receiver sensitivity. It is very easy to get radio coverage of a hamfest (i.e., several acres) when a 10- to 20-dB pad is ahead of the receiver.

Operating Notes

One of the things discovered in using the Porta-Peater with various 2m rigs was how really poor many amateur and commercial transceivers are in terms of their rf tightness. Several instances occurred where we thought the Porta-Peater was not performing right and was causing problems but found out that it was a manufactured rig which was at fault. Microphones with unshielded cables, no 12-volt lead rf bypassing, and plastic cabinets or face plates all contributed to problems. In a high-density rf environment (like the Dayton Hamvention), a rig which is not truly rf tight will give a lousy performance.

Therefore, if the Porta-Peater exhibits problems which could be contributed to rf leakage, check the rigs you are using first. A tight enclosure, with shielded and bypassed leads, will make a world of difference.

Pocket Porta-Peater?

The development and construction of this unit was really a challenge for us. Generally, it was fun (although WA2BHB seems to have less hair now than at the beginning of this project!). However, since the Porta-Peater was designed, Icom has, of course, come out with its new IC-2A synthesized HT. So, if we had a miniaturized Porta-Peater and two IC-2As, we literally could have a pocket-sized repeater that was no less frequency agile!

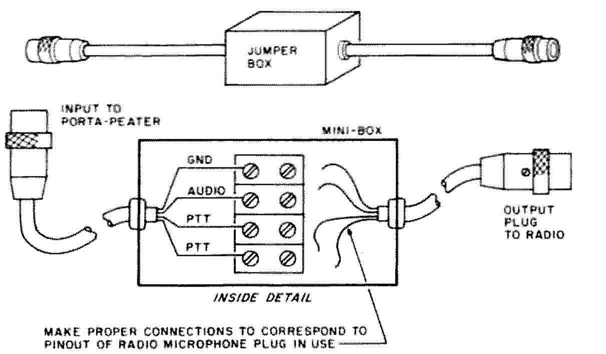

Fig. 6. A jumper box will solve the problem of a fistful of audio cables. Use shielded box and cables only.

Well, the Pocket Porta-Peater is in development. It uses a lower current drain IDer, advanced IC VOX system, is smaller in size, but it does cost more (unfortunately, some smaller parts cost more than their bigger brethren). However, if you don't need to carry a repeater in your pocket, the present version represents the best bet.

Follow-Up

I will gladly answer any questions on the Porta-Peater, but you must include an SASE if you expect a response. Please remember, I'm a ham, not an electronics engineer, so the quality of answers must be gauged accordingly. 73s, and I hope you have as much fun with your Porta-Peater as we have had with ours. ■

Amateur Television's Stripper

—a home-brew star

(Ed. Note: For further information about this article, readers should consult the "Corrections" section of this issue.)

Of the many different ways in which radio amateurs participate in our wonderful hobby, amateur television is probably one of the least understood by the general ham population and virtually unheard of by the general public. I am not referring to slow-scan TV, but to old-fashioned, regular fast-scan television.

Since I was actively involved in TV broadcasting about twenty years ago, in the days of black and white, I knew of the limitations involved. We used to pump out 16 kW of visual rf and about 10 kW aural and were happy to be informed that some viewers 40 miles away could still actually see us, which was not always the case. You can see that I was always very skeptical of the concept of amateur television. What was the point of proving that we could squirt a live picture a few blocks away? Big deal, right?

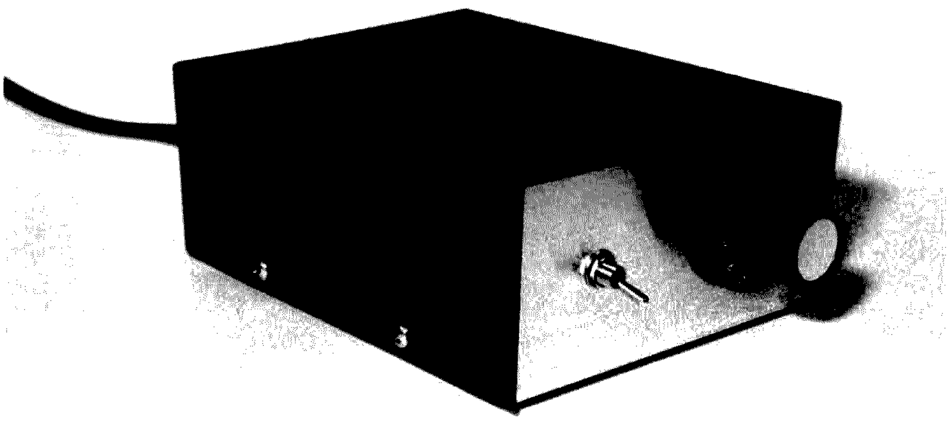

Photo A. The completed ATV converter.

Now I am here to tell you that I, and anyone thinking along the same lines, could not be farther from the truth. About five years ago, one of our local club members found out that I was trying to build my own TV camera and talked me into experimenting with some simple ATV equipment. After puttering around for a few weeks and optimizing a 6-element yagi, commercial TV converter, and a ½-Watt, 6J6-type free-running modulated oscillator, we actually managed to work over a path of thirteen miles. We were so enthusiastic that we wrote articles to several club bulletin editors to mark this great local breakthrough. There was no turning back now. I proceeded to push ATV from then on by demonstrating at ham

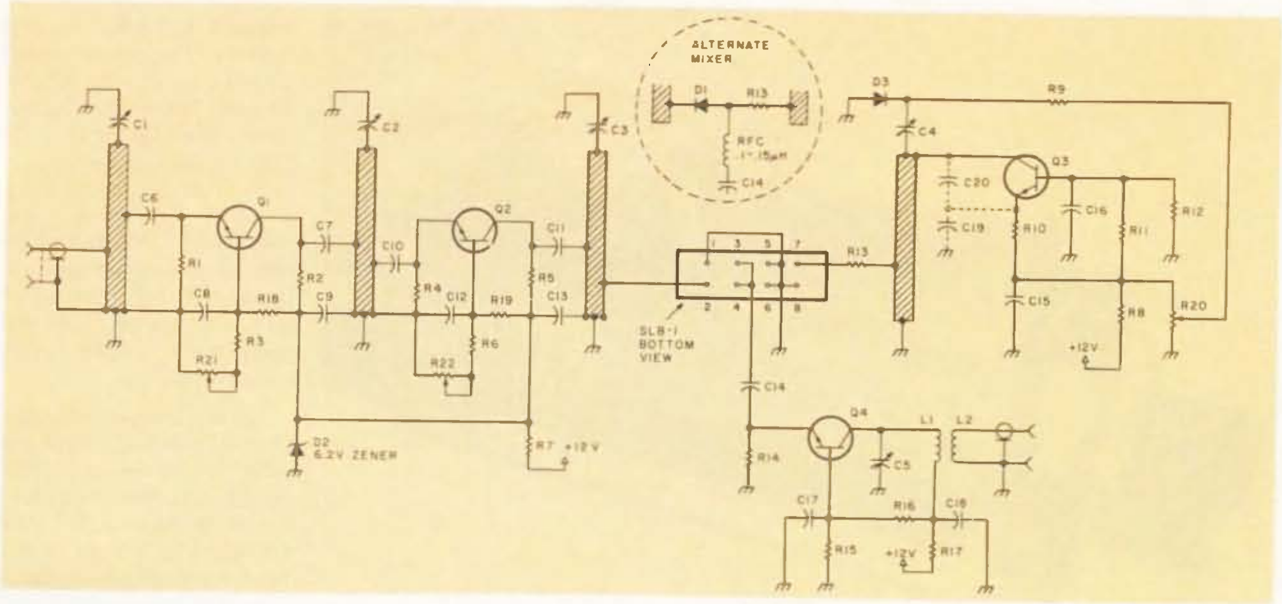

Fig. 1. ATV converter schematic.

clubs, hamfests, shopping malls, etc., and lecturing others on the pros and cons of ATV.

I have learned a great deal since that early beginning and, so, would like to pass on some helpful information to other hams who might want to follow in my footsteps.

First of all, ATV is not for everybody. I have seen many people come and go over the years. If you are not really that much interested in the workings of radio, from a scientific point of view, then forget it. Even if you buy all your equipment ready-made and get involved with your local ATV gang, you would soon lose interest because all they ever talk about and show you are ATV parts, circuits, theory, etc., until it comes out of your ears.

There are times when no one will be on, and that's usually when you want to demonstrate to your friends that you own channel 13½ and can do the same as your local station, only better. Other times, you may want to tune up your new preamp and find no one on; it can be frustrating. But there are times when another ATVer calls you on the land-line (or on 2 meters) and tells you that the band (70 cm) is wide open because the UHF TV stations are coming in like gangbusters. You will then drop whatever you are doing and get on the air right away, only to find out that all hell has broken loose on ATV—everybody and his brother seem to be coming in on a night like that.

You find yourself looking at a lot of co-channel interference, sometimes three stations at once. You turn your beam like crazy trying to separate them, while everybody is asking you via 2 meters to switch your transmitter on as well. You go bananas trying to videotape and play back, make pictures with your Polaroid, and keep track with your log sheets while simultaneously panning cameras, showing logos, etc. These openings occur more frequently than one might expect, depending a lot on your geographical location.

Around the Great Lakes region, we have a lot of thermal inversions. During the warmer weather from early spring to late fall, I can work W3POS in Erie PA at least a few times a week, and we are 85 miles apart.

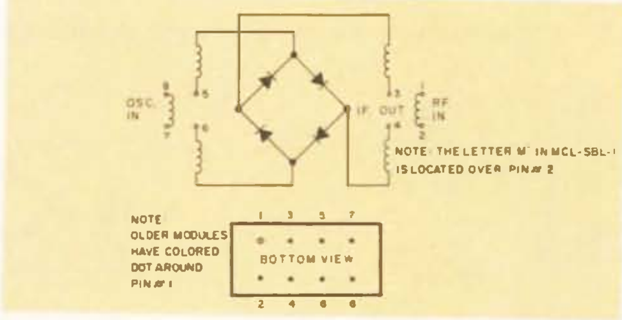

Fig. 2. Double-balanced mixer hookup details.

Last year, I worked W9ZIH in Chicago IL, which is 420 miles away from me. I also have seen K9KLM and N9AB who are up to 440 miles away from me. (See December, 1979, *73 Magazine* Letters, p. 226, or November, 1979, *A5 Magazine* for more details.)

With my present setup, I can work stations within a 50-mile radius quite comfortably. I put out 50 Watts of rf on 439.25 MHz, with sound on the video carrier, into a compact skeleton-slot antenna. (See March, 1969, *CQ Magazine* for more details.) I usually can see a 10-Watt station quite well, providing he uses a good antenna system and is not located at the bottom of a pit.

In an attempt to see how low we could go, VE3QF in

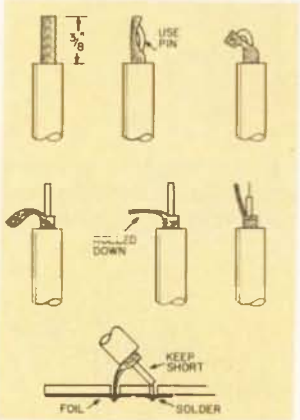

Fig. 3. RG-174 coax preparation and installation.

Toronto, Ontario, reduced his power to 50 mW into a set of four 27-element yagis and his picture frame would still lock in at my TV set. The picture quality was P½ (P5 being absolutely snow free) and we were 50

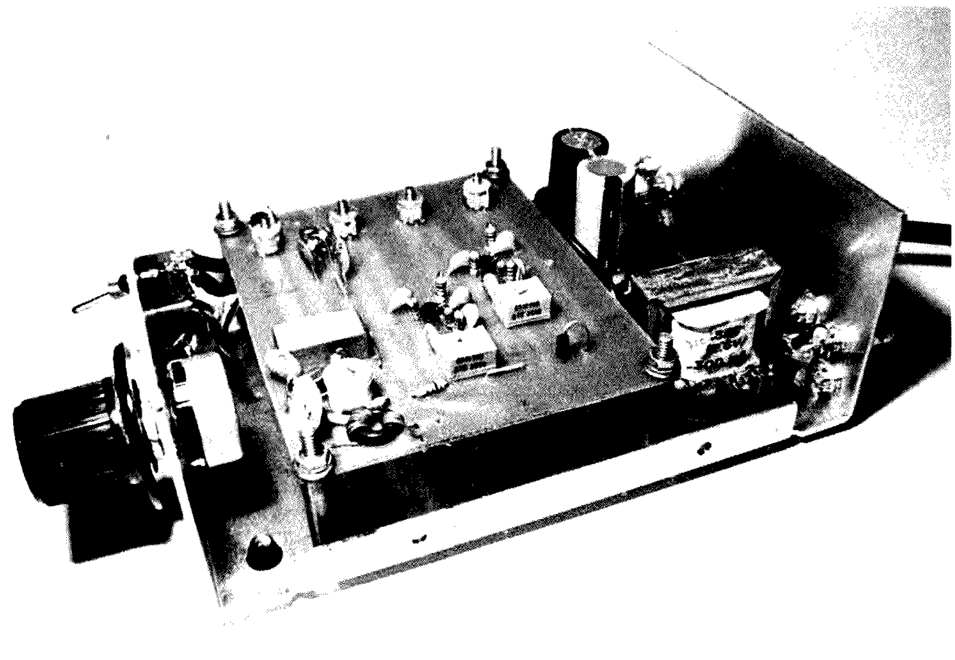

Photo B. Inside view of the converter showing PCB mounted on standoffs.

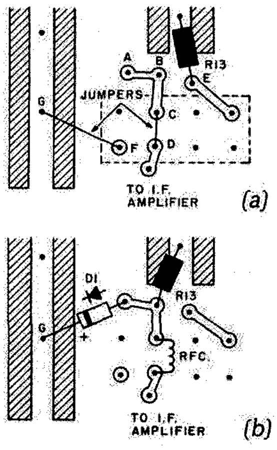

Fig. 4. Mixer installation details. (a) Double-balanced mixer. (b) UHF diode mixer.

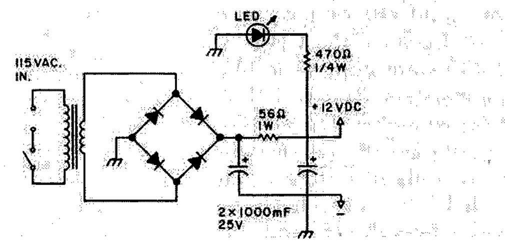

Fig. 6. 12-volt power supply.

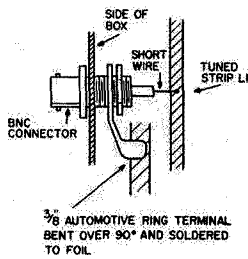

Fig. 5. BNC connector mounting.

miles apart. So, you see, with the converters, preamps, and antennas we use nowadays, ATV is really worthwhile. After all, a picture is worth *more* than a thousand words.

You, too, can do it, for it doesn't have to cost you an arm and a leg. If you are a newcomer to this TV game, make sure that there is local interest; find at least one other ATV fanatic. You will need at least one other person that you can count on for testing, adjusting, and fiddling with your video and audio equipment—it takes two to tango. Just two stations can keep busy for days, pruning and tuning. And when you drop that sharply-tuned converter, everything is out of whack again and you are set for another night of fiddling. When you've got a whole group on, you can take turns hamming it up making "Pink Rose Tea" commercials, putting on wigs or crazy caps with badges, and showing all your empty 807s.

As with any other mode of communication, the first thing to do is to be able to receive well enough. No point in playing around with old-fashioned UHF television converters, unless you are prepared to hang two or three preamps in cascade between it and the antenna. You can waste a lot of time this way and finally give up in disgust. If you can get ahold of a varactor UH tuner from a late-model TV set, you might be better off, although you still need additional amplification. Some of them will tune right down to 439.25 MHz and lower.

Unfortunately, the output frequency will only correspond with your TV set's video i-f frequency, which means you have to modify. Besides that, you do not take advantage of your TV UHF tuner's gain and selectivity. You also could build an ATV converter from various kits that are advertised in some ham publications, but my experience tells me that you will still need more amplification and selectivity.

Among the best preamps that I have built over the years were the ones that used tuned lines. The problem with them is that they are a bit tricky to make. You've got to be a combination of plumber and sheet-metal worker and you'll still end up with an amateuristic-looking contraption.

A couple of years ago (during a quiet ATV night), an idea came to me. Why couldn't I use stripline techniques instead of gas pipes and sheet copper? After all, they use it on rf power amplifiers for VHF and UHF. I decided to take one of my pet construction articles (see 1971 ARRL *Radio Amateur's Handbook*, page 417), of a 432-MHz preamp, and convert the tuned-line dimensions to stripline. I ended up with a printed circuit board that was a two-dimensional copy of the original three-dimensional preamp.

After I completed the new preamp, it took me a while to get things stabilized, but I got it working—surprisingly well, I might say. As a matter of fact, the results were so impressive that I supplied a number of ATVers in the area with similar preamps. I've made a few more since then, each time changing the dimensions a little bit; the objective was to make it smaller and simpler. Eventually it evolved into a complete converter.

The converter (Fig. 1) which will be described in

Reader Service for facing page ✓5→

this article is actually the seventh in the series, each one being an improved version of the former one. This one consists of two stages of rf amplification, one varactor-tuned oscillator, and one i-f amplifier. Also incorporated is a double-balanced mixer (more about this later!)

If you are not in the market for a complete converter, you might be interested in just copying the rf sections. Or, you might like to use the i-f (channel) amplifier separately between your own converter and boob tube for another 6 dB of gain. You also could use the oscillator as a self-contained unit to be used as an independent UHF signal source.

I will now describe each section individually so that you can take out whatever section you might be interested in. Later on in this article we will put it all together and make a complete, tunable, high-gain ATV converter.

The Rf Section

As I said earlier in this article, you can find the theory on this two-stage preamp in the 1971 and older *Handbooks*. Although we now use stripline, it seems to work basically the same way. In some earlier attempts, I used feedthrough capacitors and even used separators between stages, as well as carefully-selected bias resistors. Even though I had the thing working, I didn't want to press my luck at that stage and try anything more radically different than what I had already done with the tuned-line (tubing)-to-stripline conversion. In more advanced models, we got rid of the feedthroughs (too expensive) and separators and even tried a whole range of replacement transistors. We finally settled on what we've got now, it seems to be the best, cheapest, and easiest way to go.

The rf amplifiers could be used as a one- or two-stage preamp. Both PCB layouts are provided so that you can take your pick. The one-stage job was carefully evaluated by Ralph W2RPO, using professional equipment. The test results indicated a 15.3-dB gain at 440 MHz, with a bandwidth of roughly 20 MHz between 3-dB points. Noise figure was not measured but is assumed to be close to the 1.7-dB mark, as the manufacturer of the MRF901 states. Even with the best modern TV UHF converters, a one-stage preamp like this one should make quite an improvement, at least another P unit, as we ATVers call it—maybe even two P units.

The two-stage preamp

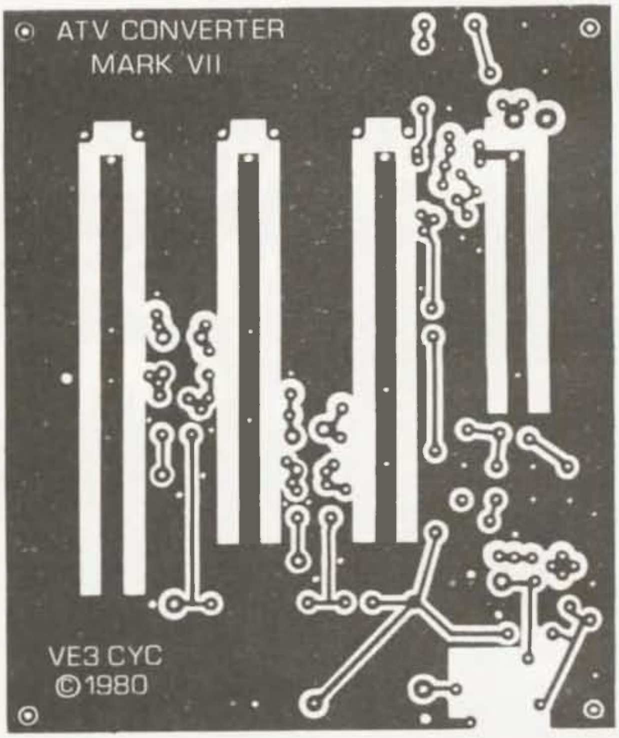

Fig. 7. ATV converter PCB layout.

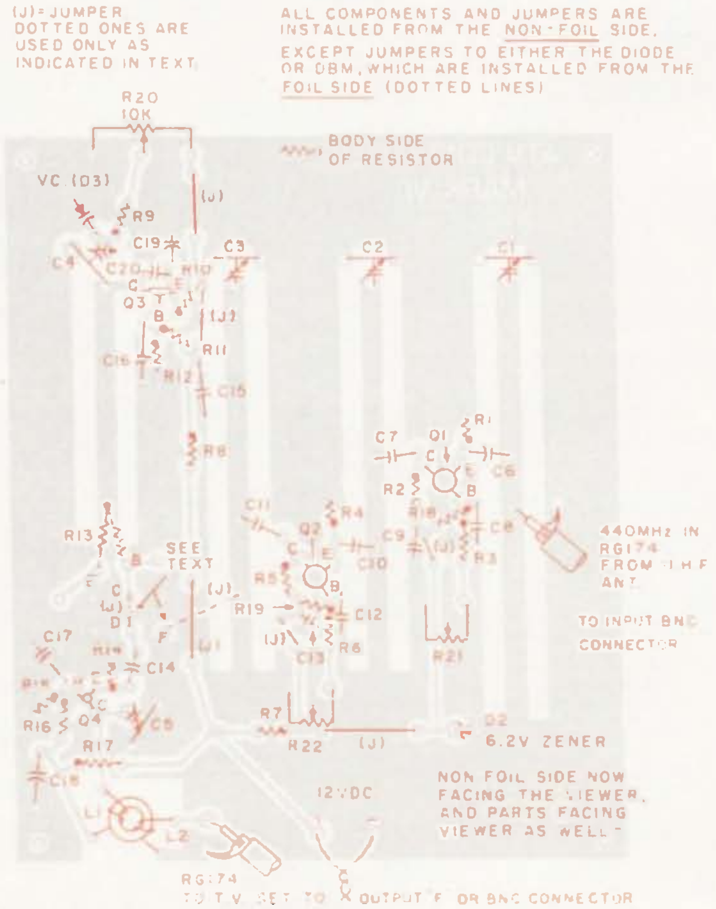

Fig. 8. ATV converter component location.

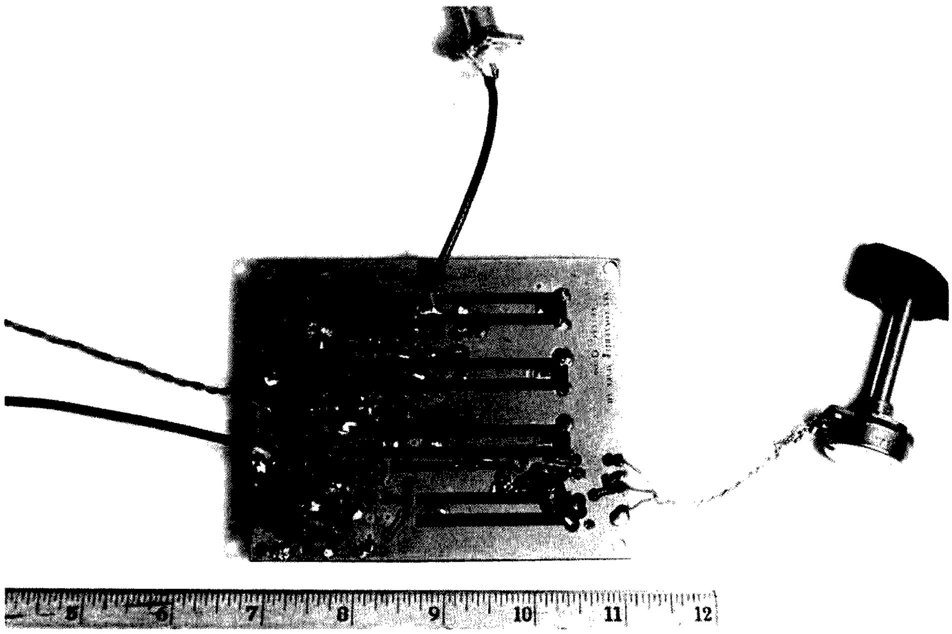

Photo C. *Foil side view of converter with input, output, power, and frequency control connections.*

will give about 40 to 50% more gain over the one-stage preamp. Therefore, you will have to decide whether it is worth the effort—it will make a day vs. night difference on those old tube-type converters like they used to have years ago—I can vouch for that.

I have dropped the 12 V down to about 6.2 V, which improves stability and keeps the noise figure down. You might try a higher voltage for more gain if you wish by changing the zener and dropping resistor values, but it will be trickier to tune up, especially when you live in intermod alley.

The Oscillator

It is not easy to make an oscillator work well with direct output in the 70-cm band. I had tried several schemes until I found this one. It originally had been developed by Tom O'Hara W6ORG, and it's used extensively in Tom's own products (PC Electronics). I have received Tom's permission to use his oscillator in this article.

Besides the change to stripline, I also changed a few values of parts, mainly to be more adaptable to other transistors (he uses the MPSH81) but also to keep the whole thing from radiating too much and getting into my scanner, etc. The two silver-mica capacitors, C19 and C20, are not always necessary with some transistors; the Sylvania ECG106 does a good job without them. These capacitors will lower the tuned frequency, and as a rule, the higher the value, the easier the oscillator starts and the less it drifts (try to keep the ratio about 1:3). If you've ever worked with regenerative UHF receivers, you might recognize the principles of this oscillator.

To preset the oscillator, it is best to set the 10k frequency control at mid range, clip a lead from a frequency counter to the output end of the 47-Ohm resistor (R13) and ground, and tune trimmer C4 to read 372 MHz for a 439.25-MHz video frequency in your area, providing your TV channel input would be channel 4. If you choose channel 3, your oscillator should be set at 378 MHz, and for channel 5 it should be 362 MHz, etc.

The carrier frequencies of channels 2, 3, 4, 5, and 6 are 55.25, 61.25, 67.25, 77.25, and 83.25 MHz, respectively. The sum of your chosen channel frequency and the oscillator frequency should be 439.25 MHz in this case, and correspondingly different for other ATV frequencies. If you don't have a frequency counter, you could use your TV set tuned to channel 59 or 60 and look for the second harmonic. The 1k resistor (R8) might have to be lowered if the oscillator fails to start.

I have tried several types of low-power PNP silicon UHF transistors, and most of them oscillate readily in this circuit. However, some have a tendency to drift more than others. The drift is not objectionable though, as it has to drift at least a few MHz to affect the video, which is seldom the case.

The I-f Amplifier

The main reason for the amplifier was to overcome the conversion losses in the double-balanced or the diode mixers, which is about 6 to 7 dB. The T37-2 toroid seems to be a better match than a T37-10 or T37-12 which I also have tried. The tuning is smoother and the tendency to oscillate has disappeared. The wire size is not critical; I have used #24 to #30 wire with equal results.

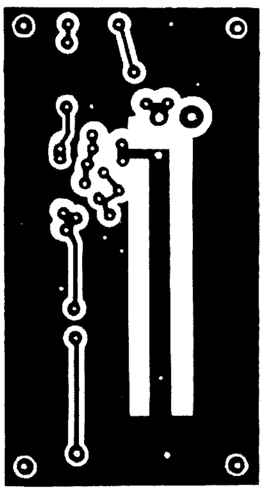

Fig. 9. UHF oscillator board PCB layout.

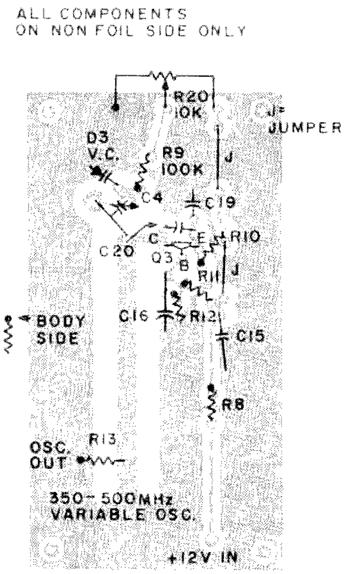

Fig. 10. UHF oscillator board component location.

Reader Service for facing page ✓451→

This amplifier can be tuned up by hooking it to your TV set's unbalanced input (75-Ohm). On some older sets, you might have to go past the balun directly to the VHF tuner input. Apply power, clip a piece of wire to C14, and tune for the best picture on the channel of your choice or the next one, if the channel is blank. That completes the tuning.

The Mixer

When I started writing this article, the only mixer worth considering, in my opinion, was a double-balanced mixer (see *The Radio Amateur's Handbook* for details). The one I selected was the MCL-SBL-1 (see Fig. 2) for no other reason than availability. There is no question about it. They do a fine job in this circuit. But in small quantities they are rather expensive.

So, just for you cheapskates out there like myself, I included a makeshift mixer, which consists of two parts: a home-wound rf choke and a small-signal diode. How cheap can you get?

Despite its simplicity, this cheap mixer works very well. The conversion losses seem at least equal to if not less than the double-balanced mixer, but it is slightly more prone to intermod (at least when you live within a mile of FM and TV stations as I do). Nevertheless, it is a good substitute until you can get a double-balanced mixer—or you could use it permanently.

Construction and Tune-Up

The printed circuit boards are made of single-sided G10, 1 oz. copper-clad laminate. After you have obtained your board, either through your own efforts or otherwise, it is best to make sure that all parts have the proper hole sizes (i.e., #62—resistors and capacitors; #60—MRF901 transistors; #56—trimmer capacitors; 1/16"—coax braiding, etc.).

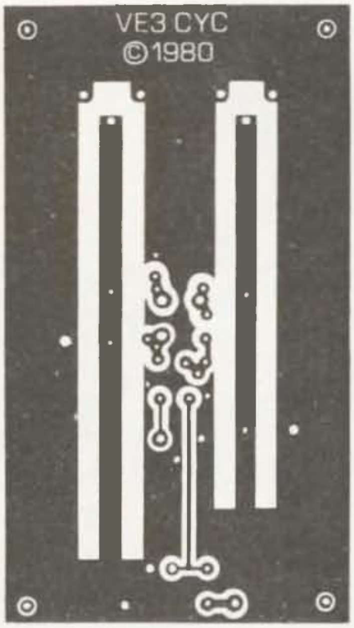

Fig. 11. One-stage preamp board PCB layout.

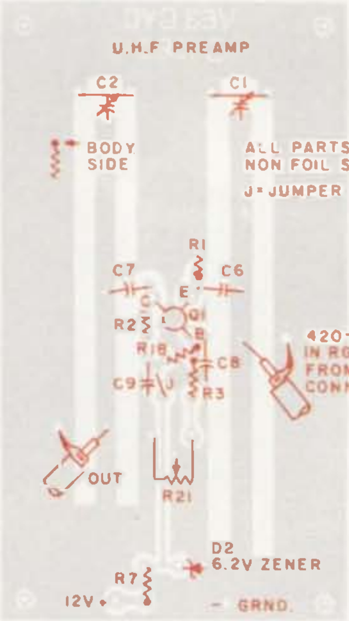

Fig. 12. One-stage preamp board component location.

Place all trimmer capacitors and trimmer resistors in their respective positions. Some of these parts might not line up right away; you might have to bend the pins to fit them. These parts must be flush with the board before soldering.

Next, I would suggest that you install all the jumper wires. (Refer to the component location figures for positioning of all parts and jumpers.) Install all capacitors, chipping off excess material around the leads as may be required to place them flush with the board. Then install the resistors, leaving the 12-V side of R7 and R8 detached. Make sure that these are flush as well, as shown in the photos. Always install them with their bodies

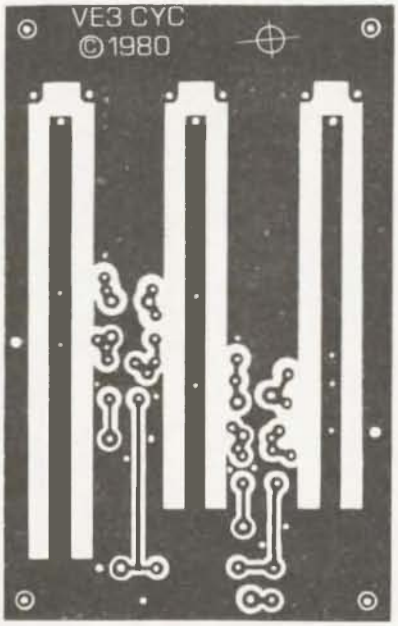

Fig. 13. Two-stage preamp board PCB layout.

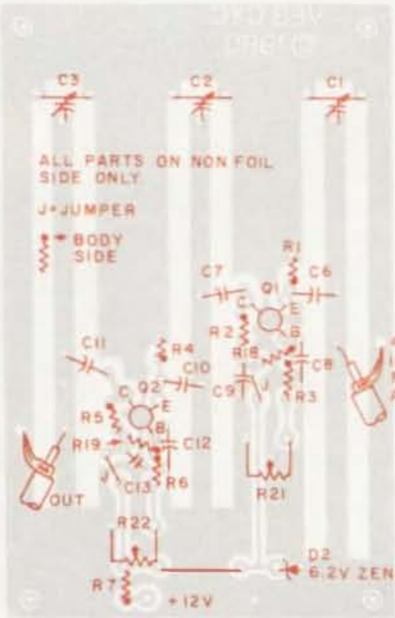

Fig. 14. Two-stage preamp board component location.

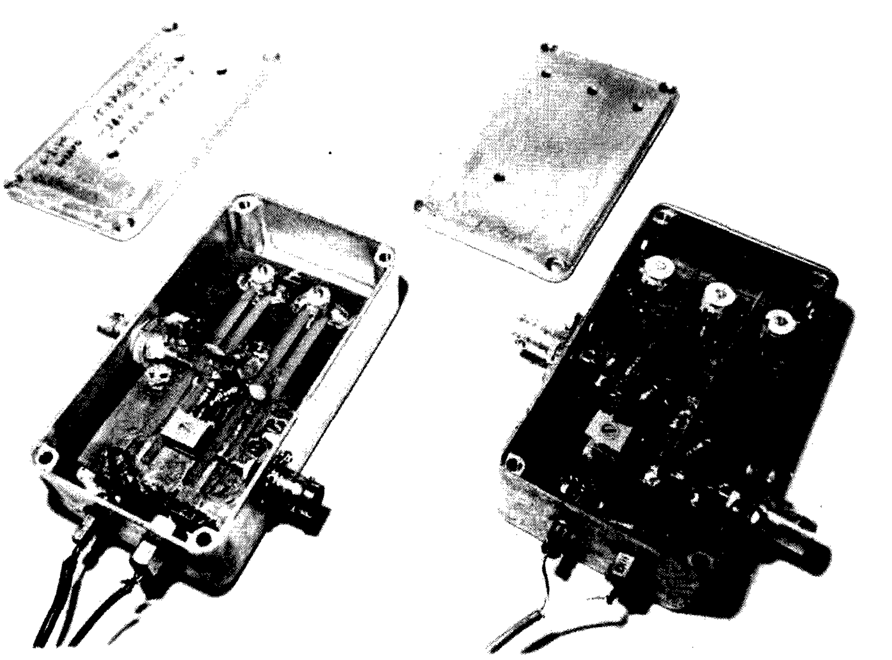

Photo D. Completed preamps in metal enclosures.

toward the rf side and leads toward the ground side.

Now install the transistors and diodes. Observe proper pin connections on the transistors and polarity on the diodes. Use a small soldering iron on this job and don't apply too much heat, as the copper foil may come loose. Never use a soldering gun on this kind of work—it might kill your transistors.

Install the remaining parts (toroid coil, rf choke, double-balanced mixer), then the power leads, three wires to the tuning potentiometer, R20, and the input and output cables from the board to the connectors. Make sure that the inner leads of each RG-174 cable to the board are as short as physically possible. A neat way would be to fish the inner lead with a pointed object through the side of the braided shield. About 3/8" from the end, roll the braided material to a smaller size between your finger tips, and solder in the ground hole as indicated in Fig. 3.

Normally, I would have included a couple of 1N914s back-to-back across the input for protection, but I skipped the idea, since it would just give you a false sense of security. Besides losing a little gain, I found it to be very ineffective when it comes to rf overload protection.

I have blown away a small fortune on replacement transistors in the process, despite the presence of the diodes. They even blew without any battery power hooked up every time I switched my 100-W linear on.

After throwing away my home-brew antenna relay (made from a conventional relay) and replacing it with a proper coaxial relay, my problems were solved. At this frequency, you only need a few pFs of stray capacitance between the relay parts to pass enough energy to knock that front-end transistor from here to the moon and further while the diodes just sit there laughin' at you. It doesn't seem to bother them.

Depending on whether you go for the double-balanced mixer (DBM) or the diode mixer, you will have to make some minor changes accordingly. Referring to Fig. 4(a), if you use the DBM, you will have to join C and D, hook R13 to E, and join G to F with a jumper wire as shown. Referring to Fig. 4(b), when using the diode mixer, join G and A with the mixer diode, D1, keeping the positive (banded) side on G, and hook R13 to B—that's all. *Make sure* to install the DBM from the component side of the board, and solder all 8 pins to the appropriate traces and ground connections. Note: To prevent C14 from accidentally shorting against the DBM, it might help to keep some clearance between the mixer module and the circuit board (about 1/16" will do).

I have used several types of diodes (silicon and germanium) and most of them seem to work quite well. A 1N82 UHF diode I tried seems to be a good choice. Hot-carrier diodes were disappointing in this circuit. You might try different ones yourself as most small-signal diodes work well in the GHz range.

In regard to the independent preamp boards (one or two stage), they should be installed in a metal box of some kind. I have used die-cast aluminum boxes for this purpose. The boards should be mounted away from the walls of the box as near to the center as possible by using spacers. If the box is small enough, you could possibly solder it right onto the BNC connectors as I did (see Fig. 5 and Photo D). Use a 0.001-μF feedthrough capacitor to feed 12 V in.

Preamp or Converter Alignment Procedure

While I explained the alignment of the oscillator and i-f amplifier earlier in this article, I will now proceed with explaining how to align the preamps and also the complete converter assembly:

1) Connect output to TV set, tune in your favorite i-f channel, and clip a length of wire to C14. Apply 12 V (Fig. 6, for example) to supply line and tune C5 for maximum on TV set.

2) Set R21, R22, C1, C2, and C3 to mid-range.

3) Tune TV to a low UHF channel that has a program on. Connect UHF TV antenna input to C10, R4, or Q2's input by spot-soldering a wire onto one of these spots. Connect a UHF antenna to antenna input on preamp or converter board. Hook a 12-V supply to R7 and ground.

4) Peak up C1, C2, and slowly turn R21 counterclockwise until a point of maximum gain is reached. If R21 is turned too far, the stage will break into oscillation; it should be kept just below this point.

5) Disconnect wire as installed in step 3, hook UHF TV's antenna to output of 2nd rf amplifier (connecting point to either D1 or SBL1, whichever is applicable), and peak up in the following order: C3, C1, C2, R22, and R21.

Reader Service for facing page ✓15→

6) Repeat step 5 a few times until everything tunes smoothly. Be careful to keep R21 and R22 below the oscillating points. By now, you should notice quite an increase in gain on the UHF channel.

7) Tune oscillator as described under "The Oscillator" by applying 12 V to R8.

8) Solder R7 and R8 to 12-V line.

9) Peak up complete converter once more, step-by-step, to a distant ATV signal source.

10) After you close up your box or whatever metal housing you decide to use, you will have to touch up the adjustment a little to allow for detuning caused by the metal shield. If your box is the kind with slots in it, you could reach some trimmers with a narrow tuning tool, and after turning the shield half a turn, do the same with the remaining trimmers. In other cases you might accomplish this feat by using a temporary cover made from a tin can with some holes punched in it.

By now you should be able to pick up ATV stations 40 to 50 miles away, and hand out P4 picture reports, while others wonder how you do it; they only get a P2 picture or nothing at all. If you've got money to burn, you might want to use a $20 transistor in the front end with a 0.9-dB noise figure, but I wonder if you'll notice much difference.

Some Afterthoughts

If you run out of range on the 5k trimpots (R21 and R22), you could extend them by using higher values for R3 and R6. This might be necessary with some oddball transistors but if you stick with the types I mentioned, you should have no problems. If R3 and R6 prove to be too high, you can lower their values, but don't go below 220 Ohms. You won't have enough isolation between the trimpots and the rf-carrying parts of the transistor bases.

If you are interested in a wider range of coverage such as 427-444 MHz, it would be better to stagger-tune the stages a bit—439 MHz on the first rf stage and 434 MHz on the second stage for instance; this also will improve stability.

If you pick up signals that shouldn't be there while your box is closed, you might have to resort to a bandpass filter; there are some good designs in the *Handbook*, etc. I am working on one now that uses stripline techniques similar to the ones in this article. If successful, you might see it some day.

In regard to the varactor diode tuning arrangement, some suitable diodes can be found in surplus varactor TV tuners. Varactor diodes do not change capacitance in a linear response to a varying voltage, so don't expect your tuning arc to be linear with the oscillator frequency. The arrangement used here seems adequate, but you could alter the value of the tuning potentiometer, R20, and add series resistance to make the dial more linear. This, of course, will change with the kind of diode used. For instance, when R20 is 3k instead of 10k and you put a 6.8k resistor in series with the pot's ground leg and ground, your dial will cover about 6 MHz over its total arc (see Fig. 3).

You could make up a second board just for the oscillator to be used as signal sources. By carefully tuning, I managed to go as high as 500 MHz and as low as 350 MHz. When tuned to 439.25 MHz, it acts as a fairly stable low-power signal source ideal for tuning up UHF preamps.

My future plans include the development of a similar setup as described in this article, but for higher frequencies such as 900 and 1296 MHz. I am also presently working on a UHF TV exciter, intermediate amplifier, and linear amplifier, all solid state and stripline, of course!

I must thank the many Canadian and American ATVers who switched on their TV transmitters endlessly for long periods of time (which is hard on the tubes and transistors with small heat sinks and no blowers) just for me to tune up and try a newly-made preamp. And for their encouragement for me to write this article. Special thanks in this regard go to: VE3EJV, VE3CJP, VE3EYR, W3POS, W2RPO, and W2PBU.■

Parts List for Converter and Preamp Boards:

C1-4—.6-to-5.5-pF film trimmers (Phillips 010EA 5E) note #1
C5—22-pF film trimmer (Phillips 010EA 20E)
C6-14—0.001-μF ceramic disc capacitors, 1/4" lead spacing
C15-18—0.01-μF ceramic disc capacitors, 5/16" lead spacing
C19—5-pF silver mica (NPO) 3/16" lead spacing or axial leads, see note #2
C20—1.5-pF silver mica (NPO) 3/16" lead spacing or axial leads, see note #2
R1-8—1.k-Ohm, 1/4 W
R9—100k, 1/4 W
R10—470 Ohm, 1/4 W
R11—27k, 1/4 W
R12—10k, 1/4 W
R13—47 Ohm, 1/4 W
R14—330 Ohm, 1/4 W
R15,16—2.2k, 1/4 W
R17—100 Ohm 1/4 W
R18,19—4.7k, 1/4 W
R20—10k volume control (linear) Radio Shack #271-1715 or equivalent
R21,22—5k trimpots, Jim Pak #850P5K (Radio Shack #271-335, 10k, as a possible substitute only; requires one additional hole in board)
D1**—1N82 or equivalent high-speed, low-power UHF diode, or better
D2—6.2-V 1 W zener diode (1N4735), Radio Shack #276-561
D3—Varicap diode ±15 pF at 4 V (MV2205, MV2105, CGE-95, or equivalent
Q1,2—MRF901 transistors or equivalent NPN silicon UHF types
Q3—MPSH81, ECG106 or equivalent PNP silicon UHF types
Q4—2N2222
Rfc—approximately 0.1 to 0.15 μH (Cambion #2960-21-03-00) or wind your own: 10 turns #28 close-wound on 1/8" form or 1/2 W 100k resistor
Mixer*—Double-balanced mixer MCL-SBL-1 (made by Mini Circuits Lab, 2625 E. 14th. St., Brooklyn NY 11235; see '78 *Handbook*, page 306 for equivalents)
L1—5 turns of small gauge hook-up wire or #24 enamel wire on Amidon toroid T37-2
L2—3 turns same as L1
Miscellaneous parts: RG-174 coax cable, two BNC connectors, SPST mini toggle switch, LED, knob, hardware to mount board, and cabinet
*Only needed when not using diode mixer
**Only needed when not using double-balanced mixer (SBL-1)
Note #1: Transcap #24PX005 from Mouser Electronics could be used instead although you have to re-drill some holes. Similarly, Transcap #24PX020 could be substituted for C5.
Note #2: Plastic-film-type capacitors or even ceramics (NPO types) could be used as substitutes for the more costly silver mica types. Lower values such as 1 pF and 3 pF have also been used successfully.
All circuit boards, parts, built-up boards, and complete units are available from Spectrum Electronics. For price list and ordering information, write to PO Box 4166 Station D, Hamilton, Ontario, Canada L8V 4L5.

Polishing Kenwood's R-1000

—a gem in the rough

This is not intended to be a product-report type of article. There are a few improvements that can be made to the R-1000 with a little effort and some are mentioned in the advertising literature. I will say that I think the R-1000 is an outstanding receiver that has excellent stability, sensitivity, and ease of operation. Following are some comments on the suggested changes.

The R-1000 comes supplied with three i-f filters: 12 kHz, 6 kHz, and 2.7 kHz. The advertising literature mentions that the filters can be switched to use the 6 kHz for AM WIDE and the 2.7-kHz filter for AM NARROW. This is not difficult, as the filters are diode-switched and there are no critical circuits involved. Actually, all filters can be used, as will be shown.

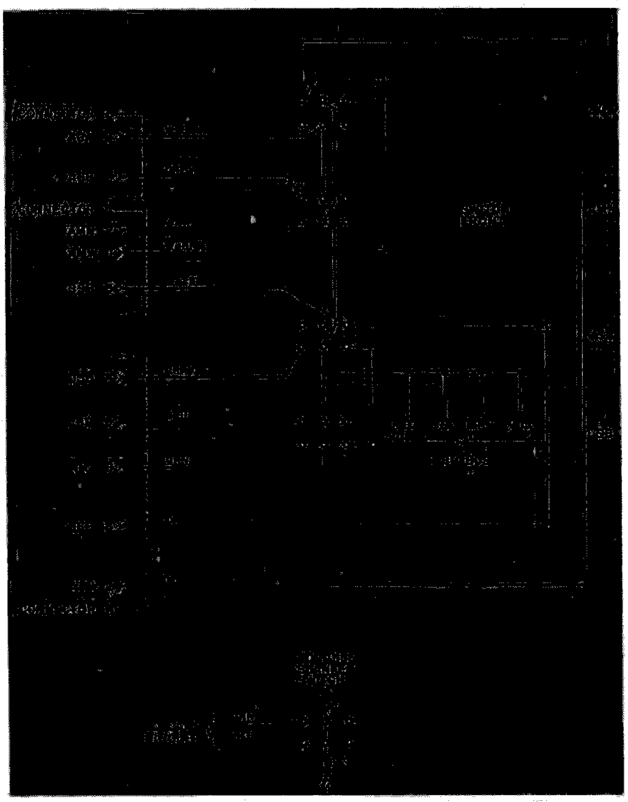

Fig. 1. Original mode switching for the R-1000. Switch at bottom is BRIGHT/DIM display control.

Kenwood goofed on the agc time-constant switching. In fact, both the schematic supplied with the receiver as well as the one in the service manual fail to show the agc switching as it is actually wired. The problem is that the fast agc is used in the SSB mode and the slow agc is used in the AM mode, just the reverse of the way it should be. Further thinking resulted in wanting the agc switched separately from the mode. It is sometimes desirable to switch to fast agc when using an SSB receiver for RTTY.

When using the R-1000 below 2 MHz, I encountered a lot of broadcast signals where they didn't belong. This is due to the fact that a single bandpass filter is used ahead of the rf amplifier for the 200-kHz-to-1-MHz range, and a second one is used for the 1-to-2-MHz range. This allows both harmonics as well as intermod products to be present. Also, while the 1000-Ohm input is probably better for the random-type wire antenna most likely to be used when tuning this range, it is probably still quite far from what the antenna impedance really is. Now for what to do about these items:

Fig. 1 shows the actual wiring of the switches as traced in my receiver. In the AM mode, 9 volts is switched to the appropriate i-f filter switching diode to activate the appropriate filter. In the SSB mode, the 2.7-kHz filter is turned on via SSB gate diodes, D51,52. The AM detector is selected by the normally-closed contacts on the SSB switches. When either AM switch is depressed, AGA and AGB are connected together, resulting in the longer time constant.

Fig. 2 shows some additional circuitry found in the service manual that did not appear in the schematic supplied with the receiver. In the AMW mode, Q47 is turned on, which grounds the negative end of C158. This extends the low-frequency response for hi-fi quality. (It is possible that the earlier R-1000s did not have this circuit, explaining why it was not in the man-

ual. If this is the case, the pin numbers shown for connector 4 may not be as shown in my drawings, but the wire colors are probably the same.)

Some comment on the display is due at this point. I feel that the bright display is too bright. Also, the display and lamps are bound to last longer if operated in the dim mode, especially if you leave the time displayed when not using the receiver. Thus, I decided to use the BRIGHT-DIM switch to switch the agc time constant.

Removing the lamp wires from the switch and taping them up leaves the display in the dim mode. (By the way, you will have to remove the front panel to make the wiring changes. This is done by removing both the top and bottom sections of the receiver case. Then remove the knobs. The bandswitch and tone knobs have hex screws; the others pull off. Remove the two screws holding the analog frequency dial knob. Then the panel screws can be removed. The mode switch is held on the front panel with two screws.)

Fig. 3 shows the change in the switch wiring I made in my R-1000. Rewiring the switches as shown not only allows use of the 2.7-kHz filter on AM, but also allows use of all three filters in both modes. This is possible due to the mechanical construction of the 4-section mode switch. It is possible to release all the buttons by pressing one in only as far as necessary to release one that is latched. It is also possible to have more than one depressed at a time. With all switches released, the receiver is in AM with the 2.7-kHz filter selected. (The 2.7-kHz filter is now switched directly with 9 volts instead of via the SSB gate diodes.) AMW and AMN are the same as before. When either USB or LSB is depressed, both AM switches are released, resulting in the 2.7-kHz filter being selected. If you desire wider bandwidth in SSB, press either LSB or USB and at the same time press AMN for 6 kHz or AMW for 12 kHz. Pressing another button will release both latched switches.

The AGA and AGB leads are wired to the normally-open contacts of the dimmer switch. Now, fast agc occurs with the switch released and slow when the switch is depressed. The strap across the common terminals is left alone. The red and black wires that go to the center switch terminals are removed and soldered together so the red lead going to the noise blanker switch is still grounded.

It occurred to me that with the 12-kHz filter in the receiver, an FM detector could be added for those who want to listen to the FM activity on the high end of 10 meters. A simple 565 PLL circuit can be added to provide this; however, it would be necessary to add a switch somewhere and also dig into the main circuit board itself to switch the audio.

For those wanting a little better selectivity for RTTY, it is possible to obtain a 1.5-kHz filter from Murata. It will be necessary to remove the main receiver board to change filters (probably best to change the 12-kHz one).

Low-frequency performance of the R-1000 can be improved with an outboard tuner. The tuner can be used with a whip, wire, or coaxially-fed antenna. It will perform impedance transformation from 50 Ohms to 1000 Ohms. A whip or short wire (most any ham antenna used as a single wire looks short at these frequencies) looks like a capacitive load. This type of antenna is best connected right to the "high" end of the tuned circuit. Fig. 4 shows a suggested tuner.

While my tuner includes several coils for three frequency ranges, I only show one here. You may wish to use ferrite rods or slug-tuned coils, but the link-winding turns should remain about the same. If your antenna has a high capacity to ground, the high frequency end will not extend as far as you may wish. This may be cured by adding about 100 to 200 pF in series with the wire antenna input on the higher frequency range. Some values are shown in Table 1.

Going down in frequency, the sensitivity rapidly drops off below 200 kHz. (The specs say 200 kHz is the bottom end of the useful range.) Above this frequency the sensitivity runs

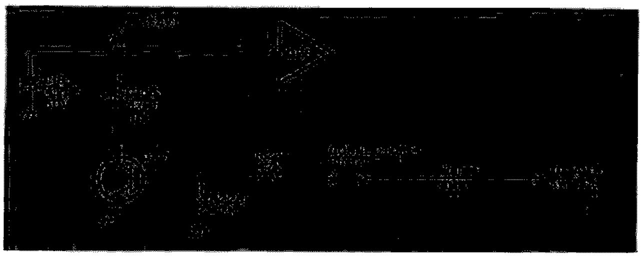

Fig. 2. Additional circuit on Q28 shown in service manual. This extends low-frequency response on AM wide.

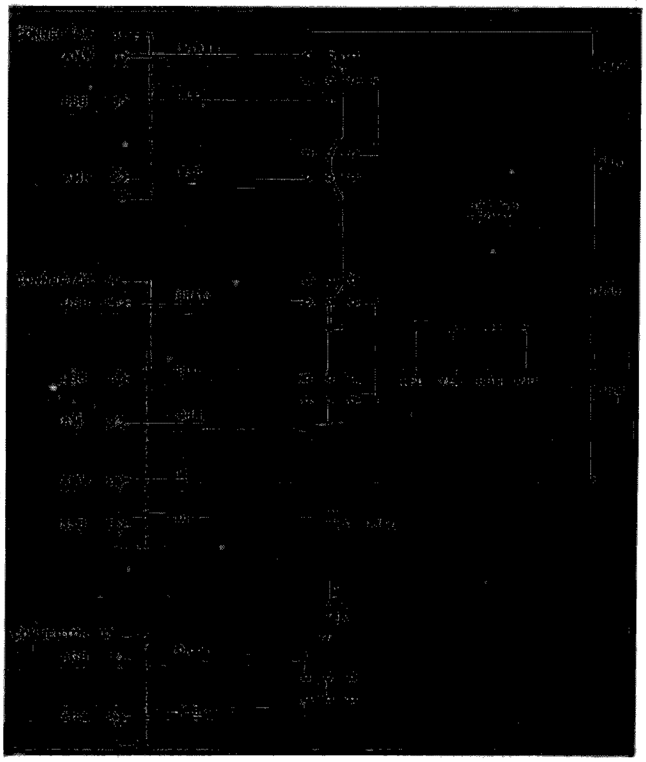

Fig. 3. Modified mode switching to provide fast and slow agc.

Frequency Range	L1	L2 (turns)	Tap (turns)
1-2 MHz	40 µH	20	5
0.5-1 MHz	150 µH	20	5
200-500 kHz	1 mH	30	6
80-200 kHz	6 mH	40	8

about 1.2 μV. At 150 kHz, sensitivity is down 16 dB, and at 100 kHz it is down 37 dB.

Being a low-frequency addict, I wondered if the low-frequency range could be extended. I felt that the filter consisting of L1, L2, L3, C7, and C8 was the limiting area. Connecting the signal generator to the junction of L4 and C9 confirmed this. It looked worthwhile to bypass the filter components, and this can be done without removing the circuit board if you are careful.

Cut the anode lead of D1 close to the board. Then cut the lead of C8 that connects to L3. Cut this lead close to the body of the capacitor. Strap the anode of D1 to this wire that went to the capacitor. Now the sensitivity is 2 μV at 150 kHz and 3 μV at 100 kHz. At 50 kHz, the sensitivity is 20 μV, where it originally was 18000 μV! This modification does not seem to increase the broadcast interference noticeably. In either case, an external tuner is needed if you are near any broadcast stations.

Kenwood sells a kit for operating the R-1000 on 12 volts dc. Why this is not included in the receiver is anybody's guess, but this feature can be easily added. There is no reason that a connector is needed on the power supply board. A pair of wires for the +12 and ground connections can just be soldered directly to the board. The power supply board is easily removed by unsoldering the wires from the power transformer. There is a blank plate on the rear panel of the receiver where the dc power connector is intended to go. A connector of your choice can be installed here. I recommend fusing the dc input with a 1-Amp, slow-blow fuse.

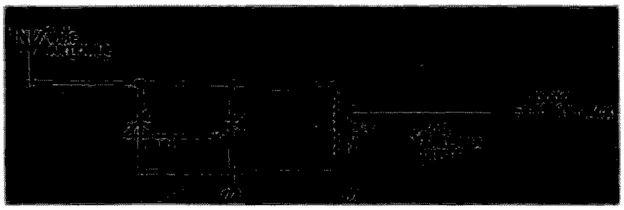

Fig. 4. Antenna tuner for the R-1000 (2 MHz and lower). C1 is a dual broadcast variable, about 730 pF.

The receiver cannot be powered by nicad batteries for very long as the current is typically around 700 mA. It draws 25 mA with the receiver off. Having the display on DIM reduces the drain by about 20 mA. Looking at the voltage readings on the drawing reveals that the audio output stage draws about 140 mA. It is evident that this stage (Q28) is inefficient because the heat sink runs quite warm.

I don't believe that there is a better device that is pin-for-pin compatible, but it still may be worth investigating replacing Q28 with something else. Also, if extended battery operation is anticipated, it might be smart to switch the displays with a momentary pushbutton switch. I estimate the displays draw 60 to 100 mA.

I did a quick check on the audio-frequency response (in the SSB mode) to see how bad it might be for RTTY. It is desirable, of course, to have a flat response at the mark and space frequencies. I originally thought that the bfo frequencies could be changed to favor RTTY operation so I did adjust the trimmers to move the bfo frequencies further from 455 kHz. They wound up at a maximum of 1700 Hz above and below 455 kHz. With the bfo readjusted like this, the response, relative to 2125 Hz, is −0.5 dB at 2295 Hz, −1 dB at 1550 Hz, and −1.5 dB at 2975 Hz. I consider this pretty good. The high-frequency response is better at the speaker output than at the record output, which was a surprise.

I hope I have not painted a dim picture of the R-1000. I think a lot of thought was put into the design. An engineer who designs equipment for the military told me that the basic rf design (synthesizer and upconverter front end with a high-frequency i-f) is the way most of the new precision communication receivers are designed. It is a fine choice for hams and SWLs alike. ■

Author's Note

Between the time I originally submitted this article and when I received the proof copy, more experiments were done on the R-1000 receiver. There have been a lot of complaints about the agc time constant being too long. I agree and therefore changed mine so the time constant compares with that of the 820 transceiver. To decrease the "fast" agc time constant, remove capacitor C217. To decrease the "slow" agc time constant, either replace C138 with a 1.5-uF capacitor or install a 2-uF capacitor in series with the AGA or AGB lead at the switch. Note that the present C138 is polarized, so if you use a polarized capacitor, connect it correctly.

To improve the high frequency response in the SSB mode for better RTTY characteristics, change C159 from .047 uF to .015 uF. This will not noticeably change anything by ear, but will produce mark and space tones of equal amplitude.

R-1000 receivers with serial numbers 009001 or higher have a jumper plug which will permit use of the 2.7- or 6-kHz filters in the AM mode. If you want to be able to use any of the three filters in either SSB or AM mode, my previous switch wiring modifications still apply.

Thanks to Ken WB9FRV for suggestions and help with the additional changes.

Peaking and Tweaking Surplus CB Boards

—the untold story

The closing of Hy-Gain's electronic assembly operations in early 1978 created a stock of readily-available surplus parts for the amateur who was willing to convert a CB printed-circuit-board assembly to 10-meter operation. These were PLL-type boards which require only two or three crystals for frequency generation. Several articles have appeared during the ensuing time describing the methods to use in converting to 10 meters. The most common method is simple crystal replacement, although some authors have opted for vco retuning.

The purpose of this article is to supplement this information with details which will describe the various boards used, and to provide correct alignment procedures.

There were five different models of board assemblies using PLL circuitry which may have made their way into the surplus market. Four of these were manufactured in Japan and have these identifying part numbers: PTBMO27AOX, PTBMO36AOX, PTBMO38COX, and PTBMO51AOX etched into the foil of the board. The fifth, manufactured by Hy-Gain itself, has the number 750096 etched in the foil and the Hy-Gain name silk-screened on the component side. This board, while very similar to the circuit used in the Japanese boards, was destined for use in the manual-switched radios and the remote-controlled model 2716 microprocessor radio; it contains mostly US transistors and ICs.

The Japanese-manufactured boards were used in model series 680, 2680, and 2700, along with some of the base stations. Table 1 gives component types, symbolism, and oscillator frequencies for boards which were used in these series.

For those who have converted factory-assembled transceivers, there may be an X or an A following the model number on the serial plate. These were identifications used to indicate various levels of FCC type acceptance, and don't have any bearing on amateur work. There may be various component differences which were required to meet tightened FCC emission requirements, but for the most part they have no effect upon the ultimate function of the unit.

Table 2 gives the same information for the remaining models of the 2700 series, and Table 3 covers the 750096 Hy-Gain-designed board.

Alignment instructions for each series will be listed separately due to changes in component identification and function. There is, however, little variation from one board to another. As in all alignment procedures, there is interaction between successive sections, so go back and forth for maximum performance. The most critical alignment in the transmitter section concerns the three final coils. Follow directions carefully, and a power output holding within ± 0.5 W can be obtained over the 40-channel spread permitted by the PLL.

There can be significant differences, from one board to another, in maximum power output—which is a function of the final amplifier transistor. Ranges will be between 3.5 W and 7.0 W. Component designations are silk-screened on the component side of the board.

Since several methods of conversion have been used, the alignment instructions are written for the original frequencies. If you have converted the board already, the relationship between the original frequencies and the converted frequencies will be obvious.
Note: Most of the components in the vco circuit have been covered with hot-melt wax to prevent movement. This should not be disturbed as component placement is critical to maintaining performance of the circuit.

Transmitter Alignment PTBMO27AOX

This board uses a three-crystal scheme. Q105 is a 9.51-MHz oscillator, Q109 is the 5.9453-MHz offset oscillator, and Q117 is a 6.4005-MHz reference oscillator.
Step 1—Oscillator Frequency Check

Q105 collector should show 9.5 MHz. Change values of C118 (nominal 47 pF) and C119 (nominal 10 pF) to correct frequency. Q109 collector should show 5.9435 MHz. Change value of C130 (82 pF) to correct frequency. Q117 should indicate 6.4005 MHz, and

C178 (39 pF) can be changed if necessary.

Step 2—Vco Alignment

Place the channel-selector switch in position 1. Using a high-impedance VOM connected between TP8 (R114) and ground, adjust T101 for 1.5 volts. Change channel switch to position 40 and the voltage should read 4.0 volts.

Step 3—Pre-Adjustment

Using a wattmeter or swr meter showing relative power output and a dummy load, turn L110 clockwise until it reaches bottom (don't over do it!). Turn L106 clockwise until power output is about 2 Watts.

Step 4—Rf Alignment

Set the channel-selector switch to position 1. Tune (in order) L103, L104, T102, and T103 for maximum rf power output. Turn L106 further clockwise if necessary to keep power at about 2 W. Change the channel-selector switch to position 40—power output should be within 0.25 W of position 1. Repeat the above procedure until this condition is met. This tuning sequence is shaping the bandpass of the rf circuit, which is capable of almost flat response across the channels if properly tuned.

Step 5—Final Circuit Adjustment

This is the most critical step in obtaining maximum power output and in maintaining the flat power response across the channels. With the channel switch in position 1, adjust L109 for maximum output, and then L110 for maximum. Repeat the adjustments. Switch to position 40 and verify that power output remains within 0.5 W. If not, L109 often has two positions for resonance, and normally the lower position is correct. Find the second position and repeat the adjustments of both coils. If this has no effect, turn L110 clockwise one-half turn and repeak the final circuit by readjustment of L109. Repeat as necessary.

Lastly, adjust L106 for maximum output. Repeak L109, and then L110 slightly, as required. Check channel 40 for power output within the 0.5-W specification.

Step 6—Modulation Adjustment

Using a scope or other modulation indicator connected to the antenna terminal (dummy load still attached), adjust RV102 for correct modulation. If a calibrated, modulated signal generator is available, put 20 mV at about 1 kHz into the mike input and adjust for slightly under 100% modulation.

Step 7—Rf/S-Meter Adjustment

The board was fabricated for use with an rf/S-meter. A suitable meter can be connected between point 6B and ground. Adjust RV104 (20k pot) to calibrate meter to the power output indicated on the wattmeter.

Receiver Alignment

This board has circuitry for anl functions which can be made operational by connecting point 39 on the PCB to ground. Do this prior to receiver alignment.

Step 1—Vco Alignment

The vco circuitry is common to both transmit and receive functions of the transceiver, and was covered in the oscillator-frequency check in the transmitter-alignment section.

IC101	01A	01A

Table 1. Components and functions for the 27AOX, 36AOX, and 38COX.

Step 2—Circuit Alignment

Use the rf/S-meter previously installed, an audio VOM connected to the speaker terminals, or a scope to monitor alignment. Set a frequency generator, or a very attenuated transmitter, to a mid-frequency (27.205 MHz if still unconverted) and very low output to avoid agc action. Adjust, in order, L115, T104, T105, L112, T106, T107, T108, and T109 for maximum output. The frequency generator should have low-level modulation if using audio output as the indicator. Since adjustments interact, repeat several times to obtain maximum sensitivity. If using a calibrated generator, check sensitivity at each band edge. Sensitivity should be less than 1 uV.

Step 3—Squelch Circuit Adjustment

Turn to maximum the external pot being used for squelch control and adjust RV101 so that an S9 signal just breaks the squelch. If you are using a calibrated generator, input a 50-uV signal at the antenna terminal and adjust for squelch break.

Step 4—S-Meter Adjustment

Using the same signal level as step 3, adjust meter-calibration pot RV103 for S9 indication.

This completes the alignment for the PTBMO-27AOX board.

Transmitter Alignment
PTBMO36AOX and PTBMO38COX

Step 1—Oscillator-Frequency Check

These boards use a three-crystal frequency scheme. Q105 is an 11.8066-MHz oscillator, and C118 (39 pF) and C119 (12 pF) may be changed to adjust frequency. Offset oscillator Q109 operates at 10.695 MHz, and C127 (56 pF) is used for frequency adjustment. Q117 is the 10.24-MHz reference oscillator, and C178 (56 pF) is used to adjust frequency.

Step 2—Vco Adjustment

Connect a VOM to TP8 (R114) and adjust T101 for 1.5 V with the channel-selector switch in position 1. Switch to position 40, and the voltage should be 4.5 V.

Step 3—Pre-Adjustment

Using a wattmeter or swr meter showing relative power output and a dummy load, turn L110 clockwise until it reaches bottom. Turn L106 clockwise until power output is about 2 W.

Step 4—Rf Alignment

Set the channel-selector switch to position 1. Tune (in order T111, L103, L104, T102, and T103, for maximum output. Turn L106 further clockwise if necessary to keep power at about 2 Watts. Change the channel switch to position 40—the power output should be within 0.25 W of position 1. Repeat the above procedure until this condition is met. This process is shaping the bandpass of the rf circuit, and it is capable of almost flat response across the channels.

Step 5—Final Circuit Adjustment

Use the same procedure as in Step 5 for the 27AOX board.

Step 6—Modulation Adjustment

Use the same procedure as in Step 6 for the 27AOX board.

Step 7—Rf/S-Meter Adjustment

Use the same connection and adjustment procedures as on the 27AOX board.

Receiver Alignment

The boards were designed with an anl function which can be made operational by connecting point 29 on the PCB to ground; this should be done prior to receiver alignment.

Step 1—Vco Alignment

The vco circuit is common to both transmit and receive functions of the transceiver, and was covered in the oscillator-frequency check in the transmitter-alignment section.

Step 2—Circuit Alignment

Use the rf/S-meter, an audio VOM connected to the speaker terminals, or a scope to monitor alignment. Set a frequency generator, or a very attenuated transceiver, to a mid-frequency and very low output to avoid agc action. Adjust, in order, T104, T105, L112, T106, T108, and T109 for maximum output. The frequency generator should have low-level modulation if using audio output as the indicator. Since adjustments interact, repeat several times to obtain maximum sensitivity, decreasing the generator output if necessary. If a generator is used, check the sensitivity at both band ends, which should be less than 1 uV.

Step 3—Squelch Adjustment

Use the same procedure as with the 27AOX board.

Step 4—S-Meter Adjustment

Using the same signal level as in step 3, adjust meter-calibration pot RV103 for S9 indication.

This completes alignment of the 36AOX and 38AOX boards.

Transmitter Alignment
PTBMO51AOX

Step 1—Oscillator-Frequency Check

This board uses a two-crystal frequency scheme in conjunction with the particular PLL circuitry used in the design. Q1 is a 10.2-MHz reference oscillator for the PLL and injects a signal into the second receiver mixer, Q10. This signal is fed into PLL IC1 where it is divided by 1024. A 10.695-MHz signal is generated and mixed with the above in IC3.

Q1 should show a frequency of 10.24 MHz. Adjust TC1 (adjacent to X1) for correct frequency. The mixer oscillator (10.24 MHz) as measured at pin 1 of IC3 can be adjusted by changing the value of C25 (4 pF).

Step 2—Vco Adjustment

Connect a VOM to TP8 and adjust L1 to obtain 1.5 V with the channel switch in position 1. Switch to position 40, and the voltage should be 3.6 V.

Step 3—Pre-Adjustment

Using a wattmeter or swr meter showing relative power and a dummy load, turn L12 clockwise until it reaches bottom. Turn L7 clockwise until power output is about 2 W.

Step 4—Rf Alignment

Set the channel-selector switch to position 1. Tune (in order) T1, L2, T2, L5, T3, and T4 for maximum power output. Turn L7 further clockwise if necessary to keep power at or about 2 W. Change the switch to position 40, and power output should remain constant within about 0.25 W. Repeat the above procedures until this condition is met. This procedure is shaping the bandpass of the rf circuit, and it is capable of almost flat response across the band.

Step 5—Final Circuit Adjustment

This is the most critical adjustment to obtain maximum power output and maintain the flat power response across the band. With the selector switch in position 20, adjust L11 for maximum power output and then L12 for a higher maximum. Repeat the adjustments. Switch successively to channel 1 and 40 to verify that power output remains within 0.5 W of that obtained in position 20. If it does not, return to position 20, turn L12 a quarter turn clockwise, readjust L11 for maximum output and recheck position 1 and 40. Last, adjust L7 for maximum output. Repeak L11

and L12 slightly for maximum output. Recheck channels 1 and 40.

Step 6—Modulation Adjustment

Using a scope connected to the antenna terminal (dummy load still attached) or other modulation indicator, adjust RV2 for just under 100% modulation. If a calibrated, modulated signal generator is available, put 20 mV at about 1 kHz into the mic input and adjust for the correct modulation level.

Step 7—Rf/S-Meter

The board was fabricated for use with an rf/S-meter. A suitable meter can be connected between point 68 and ground. Adjust RV2 (near L12) to calibrate the meter to the power level indicated on the wattmeter.

Receiver Alignment

This board has circuitry for an anl and noise-blanker function. The anl can be made operational by connecting points 31 and 41 on the PCB. When these points are not connected, the noise-blanker circuit is operational. A switch can be installed for easy function selection, and the anl should be engaged prior to alignment.

Step 1—Circuit Alignment

Use the rf/S-meter, an audio VOM connected to the speaker terminals, or a scope to monitor alignment. Set a frequency generator or a *very* attenuated transmitter to a mid-frequency and very low output to avoid agc action. Adjust, in order, T5, T6, L14, T7, T8, and T10 for maximum output. The frequency generator should have low-level modulation if using audio output as the indicator. Since adjustments interact, repeat several times to obtain maximum sensitivity and, if using a calibrated generator, check the sensitivity at each band edge. Sensitivity should be less than 1 uV.

Table 2. Components and functions for the 51AOX.

Step 2—Squelch Circuit Adjustment

Turn the external pot being used for squelch control to maximum and adjust RV1 (adjacent to T8) so that an S9 signal just breaks the squelch. If a calibrated generator is being used, input a 50-uV signal at the antenna terminal and adjust for squelch break.

Step 3—S-Meter Adjustment

Using the same signal level as Step 2, adjust meter-calibration pot RV3 (adjacent to T10) for S9 indication.

This completes alignment of the 51AOX board.

This board was made to use an LED channel display. A special channel-selector switch with an extra section of contacts protruding from the top side was mounted to the board. Another PCB assembly (PTSWO23AOX) was connected to the top of the switch and contained the LED drivers. The LEDs were mounted on board assembly PTLDO15AOX and interconnected to the driver board with flat ribbon cable. Each board connected to the identical lettered holes on the other board. Driver board PTSWO23AOX hole 1 is connected to main PCB ground and hole 2 to terminal 9 on the main PCB.

Hy-Gain produced two radios that had all of the functional controls in the microphone, the main chassis assemblies of which could be mounted in the trunk or under the car seat. This not only facilitated ease of operation but, by removing the microphone, prevented theft.

Model 2679

The transceiver used conventional PLL circuitry contained on the 36AOX board which was connected to an auxiliary control board mounted above it on the metal chassis. The control board has 750070 etched on the foil side, and 878928 silk-screened on the component side. The rear of the chassis contains a large 16-contact connector which was used to interconnect with the microphone through a specially-made cord.

The microphone was black with two seven-segment red LEDs used for channel indicators and red (transmit) and green (receive) diodes located one on either side of a silver-handled toggle switch. There are commercially-available service manuals which will illustrate the interconnection of the two PCBs and the microphone.

Since the transceiver uses the same main PCB for transmit and receiver functions, the radio can be converted in the same manner as a switch-selected channel unit. One word of caution—the mike cord was prone to failure. Buy two.

Model 2716

This radio was known as the Hy-Gain 16 and was a

state-of-the-art advancement over the remote-controlled 2679. It was completely designed by Hy-Gain and was the first remote-microprocessor-controlled radio manufactured. The main PCB used could be operated with a conventional 40-channel switch or interconnected with a logic-control board to accept serial data from the microprocessor located in the microphone.

The transceiver featured 40-channel operation, two frequency memories, an emergency switch to override all functions and go to channel 9, PA function, a switchable noise blanker, and a clock.

The heart of the system was a National Semiconductor microprocessor which was bonded to the microphone PCB. National Semi manufactured this board. It has been advertised for sale for use of the clock only. Identification on the lower left corner of the foil side is MA6008-c. The trimmer cap, IC, and crystal and associated components on the foil side are the clock. Look at the crystal frequency carefully if you have one of the boards—it's a TV crystal adjusted by the cap to give nearly correct time. Much less expensive than using a special crystal running at exactly 3600 kHz.

All functions were activated by depressing the appropriate keys, with the channels slewing up or down, and the squelch and volume controlled by 16-step control circuits.

In addition to the microphone board, the interface board (750097 on foil side and 879499 on component side) and the main PCB (750096 on foil side and 879709 on component side) were interconnected to form the functional unit.

Since the main PCB can be made operational with a conventional channel-selector switch as used on other models, the following alignment procedure is provided. Should you be able to locate all of the components necessary to construct a complete unit, consult commercially-available service manuals for connections.

Transmitter Alignment
879709

This board uses a three-crystal frequency scheme. Q105 is an 11.8066-MHz oscillator which is tripled to function with the vco. Offset oscillator Q109 runs at 10.695 MHz, and PLL reference oscillator Q117 is at 10.24 MHz.

Step 1—Vco Adjustment

Connect a high-impedance VOM to TP8 (R114) and adjust T101 for 1.5 V indicated when set to channel one. Collector of Q108 should give a frequency reading of 37.66 MHz at this time.

Step 2—Pre-adjustment

Using a wattmeter or swr meter showing relative power output and a dummy load, turn L110 maximum clockwise and L106 clockwise until power output is approximately 2 Watts.

Step 3—Rf Alignment

Place in operation on channel 1 and adjust T111, L103, L104, T102, and T103, in order, for maximum power output. Reduce output by turning L106 clockwise if necessary to remain at no more than 2 W. Repeat several times if necessary to obtain maximum power output. Switch to position 40 and verify that power output is within 0.25 W of the position 1 reading.

Step 4—Final Circuit Alignment

Follow the instructions in Step 5 for board 27AOX.

Step 5—Modulation Adjustment

Using a scope or other modulation indicator connected to the antenna terminal, adjust RV102 for correct modulation. If a calibrated, modulated signal generator is available, connect to point 22 on the main PCB and set for 20 mV at about 1 kHz, and adjust for just under 100% modulation.

Step 6—Rf/S-Meter

An rf/S-meter can be used with this board by connecting between point 6B and ground on the main PCB. Adjust RV104 to calibrate the meter to the power indicated on the wattmeter.

This completes the transmitter alignment.

Receiver Alignment

Step 1—Vco Alignment

The vco circuitry is common to both transmitter and receiver and was covered in the oscillator-frequency check during transmitter alignment.

Step 2—Circuit Alignment

Connect an audio VOM to the speaker terminals or a high-impedance VOM to point 6B (or use the rf/S-meter installed previously) and ground. Using a frequency generator or a very attenuated transmitter set for a mid-channel, adjust, in order, T104, T105, L112, T106, T107, T108, and T109 for maximum audio output.

Component and Designation	Function

		IC101 MM48141	PLL
		IC102 TA7205P	Audio amp

Table 3. Components and functions for the 750096.

Repeat the adjustments as necessary.

Step 3—Squelch Adjustment

The squelch-adjustment circuitry was located on the control interface board. To make the squelch circuit functional, connect the wiper pin of a 10k pot to PCB point 7 and a 20k resistor in series between one of the pot IR pins and point 11 on the PCB. Last, connect a 10k pot (which will be the squelch control) between point Z and ground.

Turn the 10k pot completely clockwise and adjust the 20k pot (squelch calibrate) so that an S9 signal just breaks squelch. If a calibrated signal generator is available, input 50 uV at the antenna terminal and adjust for squelch break.

This completes alignment of the receiver portion of the board.

Should any of the boards fail to align properly, start troubleshooting from the front end of the receiver or transmitter sections to locate the trouble. Since these boards were in various stages of manufacture when operations ceased, they should be inspected carefully for damaged components or solder bridges.

In some models, the detector is a 1N4148 diode (usually found after the 2nd i-f amp Q119) and it is subject to infant mortality due to solder heat during assembly. If it is replaced, leave it standing up in the air on long leads and heat sink between the board and diode body.

That is the list of boards which many hams have converted. They are very well designed items, and if in proper condition and alignment should give very good service for a number of years. ■

OSCAR Pathfinder

— a colorful way to track the satellites

After purchasing my shiny New Apple II Plus last year, I went searching through my stacks of old *73 Magazines* for some good programs to run on it. To my amazement, there was an annoying lack of articles on this machine. (Hey, Apple owners what gives?) There were a lot of programs for other machines, but I didn't feel like going through the hassle of translating them. Besides, I wanted to use the graphics capability of the Apple, and the programs I found were not suitable for graphics. So I decided that a good way to get familiar with the machine and to offer something to other Apple hams would be to write my own program. Since I have always had a lingering interest in the OSCAR satellites, an OSCAR satellite tracking program became my objective.

The features I wanted my program to have were:

1) A graphics routine to display in real time the position of the satellite being tracked on a scale map of the US along with a simultaneous display of azimuth and elevation figures for an antenna array.

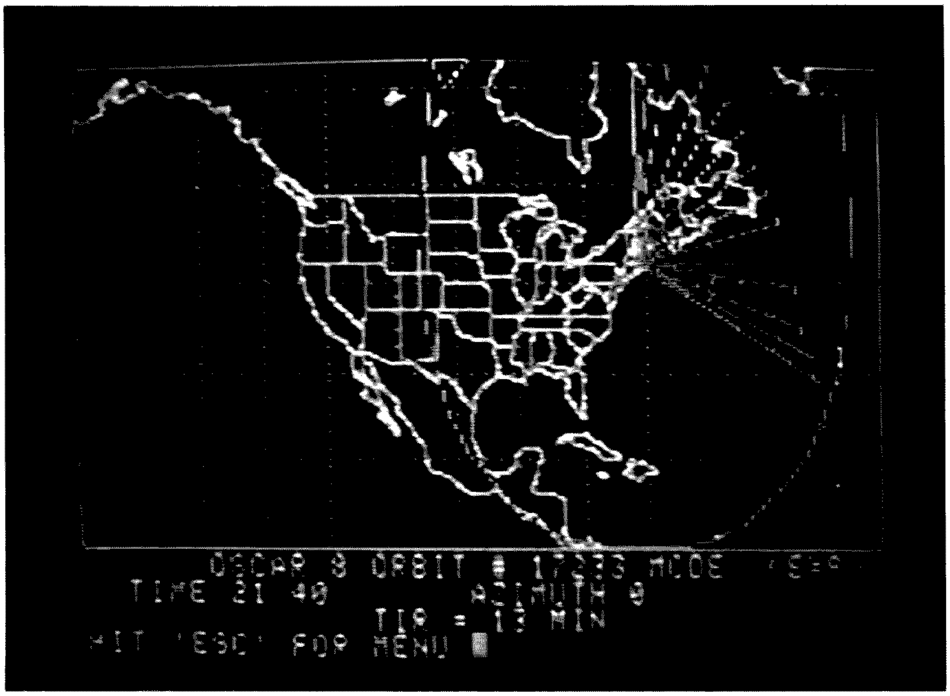
2) A routine to display a list of the azimuth and elevation figures for the orbit.

3) The equatorial crossing data for each of the orbits on the day selected.

4) A routine to display a list of the latitude and longitude of the satellite for each minute of the orbit.

Besides computing orbital data for OSCAR satellites, I wanted the capability to compute orbital data for any circular orbit satellite. Building on the basic ideas and research of the authors I have mentioned in the references, I came up with OSCAR Pathfinder.

Although the basics of the program came straightforwardly, there were two major obstacles I had to overcome before it would operate in the Apple. The first and most difficult to solve stemmed from the way the Apple memory is organized (see Fig. 1). As you can see, Hi-Res screen buffer 1 is located from 8192 to 16383. Hi-Res screen buffer 2 is located piggyback to that from 16384 to 24525. Basic programs start loading into memory at location 2048, filling up memory from there the way water fills a glass. LOMEM floats up through memory with the loading program like a cork floats up with the water. When the program is fully loaded, LOMEM is at the end of the program. Now, if the program is longer than 6K bytes, the end of the program extends up into and possibly beyond the screen buffers.



In the case of OSCAR Pathfinder, which is approximately 13K-bytes long, 7K of the program overlaps Hi-Res screen buffer 1. When the command HGR is encountered in the program, the buffer is cleared and *POOF!*—the last 7K of OSCAR Pathfinder goes off to the bit bucket.

Since the Hi-Res screens cannot be moved to another location in memory (at least as far as I know), the program must therefore be made to occupy another non-conflicting portion of

memory. With 48K of memory available, there is lots of room to use between the end of Hi-Res screen buffer 1 and DOS.

Ahah, but to get the program up there — that was the problem! Since LOMEM and HIMEM affect only the limits of variable and array space, it wouldn't help to move them around. After a lot of PEEKing, POKEing, hair pulling, and studying of the Apple manuals, I discovered the fact that the Apple uses software pointers to indicate the beginning and ending of BASIC programs in memory, along with other various pointers, all located in page Zero. Locations 103 and 104 ($67,$68) make up the pointer to the program's beginning address.

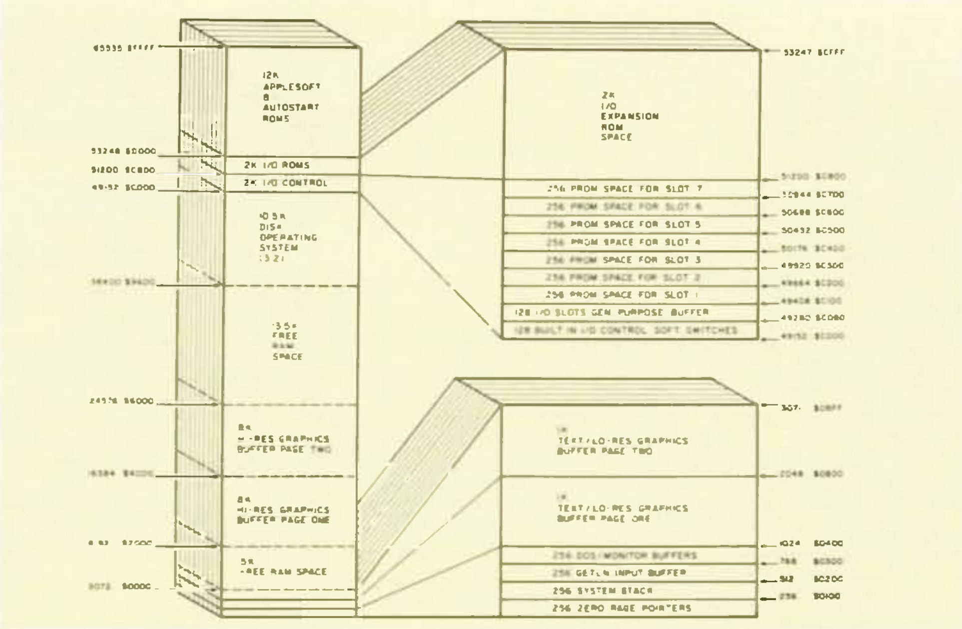


Fig. 1. 48K Apple II Plus memory organization.

After a little experimenting, I discovered that by changing the contents of this pointer I could control the location at which the BASIC programs start loading. *Success!* Now by typing the command "POKE 104,64:POKE 103,0:POKE 16384,0", I set the address of the beginning of a BASIC program to 16384, immediately following Hi-Res screen buffer 1. Since Hi-Res screen 2 is not used at all in OSCAR Pathfinder, I didn't have to worry about it causing any problems. OSCAR Pathfinder could then be loaded into memory and would reside from 16384 on up, with plenty of room left available for variables and arrays between the end of the program (LOMEM) and DOS (HIMEM).

This memory shuffling is accomplished by the small program, OSCAR STARTER, which appears in Listing 1. OSCAR STARTER will then cause the main program (Listing 2) to load from the disk and run.

The second major problem encountered was how to get an accurate scale map into the screen buffer for the program to plot on. I had two options that I knew of. One was to obtain one of those fancy sophisticated graphics digitizer tablets—which costs lots of bucks. The other was to do it by software—which costs lots of hours. Since I had lots more hours to burn than bucks, I chose the latter method. I decided that by using *lots* of HPLOT instructions, I could draw the necessary map.

The map I chose to put into memory was a Mercator projection because the latitude and longitude lines were straight, easing the math requirements to plot coordinates. In order to obtain the X, Y coordinates for the HPLOT commands, I traced the map on some graph paper which had a sufficient number of vertical and horizontal lines to provide reasonable resolution for the map. Then by numbering the vertical lines from 0 to 279 and the horizontal lines from 0 to 159, I was able to come up with the X,Y coordinates of all the major features of the map. (Believe me, that's a lot of dots!)

The resulting program is given in Listing 3. Since its length extends into Hi-Res screen buffer 1, either the same relocation method used to run OSCAR Pathfinder may be used or one could split the program in half and draw the map in two steps. Running the program results in a map of the US, Mexico, and Canada with latitude and longitude lines for every 10 degrees. To save this map for later use by OSCAR Pathfinder, first enter and run the program in Listing 3. Then use the BSAVE command to save the map on disk as a binary file. Use the file name "MAP 1." OSCAR Pathfinder will load the map as needed.

Operation

As you might already have deduced, OSCAR Pathfinder was originated on a 48K Apple II Plus machine with a single disk drive. When run, OSCAR Pathfinder first sets up variables, arrays, and formulas. Then it asks you for the data necessary for computation. The program computes the data for the orbit you select and then offers a choice of display modes.

The first information to be entered is the position of the station in longitude and latitude, in the range of −180 to 180 degrees and −90 to 90 degrees, with east longitude and south latitude entered as negative numbers. The data is checked to be sure it is in the proper range. Next, OSCAR Pathfinder asks the user for the date of the orbit to be computed. This is entered in six digits, two each for day, month, and year. The program checks the entry for proper range. Then the day of the week for the date entered is requested, to be used later in determining the mode of operation for the satellite.

OSCAR Pathfinder then requests the name of the satellite and, if it is not an OSCAR satellite, it then requests the orbital parameters for that satellite. The program asks for the northbound equatorial

crossing (EQX) data for the reference orbit for the date selected earlier. This data is entered as (1) orbit number, (2) EQX time of day in the format HHMMSS, and (3) the EQX longitude with the west longitude being positive.

The program then computes the equatorial crossing data for each of the orbits for that date. The desired orbit number is selected from the list presented by entering the reference number associated with it. The program then begins its major number-crunching routines, generating latitudes, longitudes, bearings, and ranges for subsatellite points (SSP) in one minute intervals for the orbit, and computing elevation to the satellite for each minute the satellite is within range (above the horizon).

The computing time for SSP data is approximately 1.4 seconds for each minute of the orbit. For example, if the orbit is 100 minutes long, it would take about 2

minutes and 20 seconds to compute all the satellite data. (Try doing it in that time on your calculator!)

Display Menu

Finally, with all data computed, the program goes into the display mode, starting out with the display menu offering the choice of (1) real-time graphics, (2) high speed graphics, (3) azimuth-elevation list, (4) SSP data list, (5) orbits for the day, (6) compute data for another one of the orbits of the day, (7) start the program over, and (8) quit. If, while any of the display routines is running it becomes necessary to access the display menu again, pressing the ESC key will accomplish this. This allows one to jump around the display modes without having to wait for each one to finish.

If the real-time graphics choice is selected, the computer loads the map from the disk into the Hi-Res screen buffer 1. Then, if the satellite path is within the

bounds of the map, it draws the satellite path and range circle and displays the satellite name, orbit number, and mode of operation. The computer then requests the operator to press the space bar when the actual time of day matches that displayed on the screen (which is the time of Acquisition Of Signal—AOS). When that is done, the computer begins its real-time display procedure, during which it displays the current satellite position along the path, with a bearing line from the station to the current SSP, the time of day, the time remaining until Loss Of Signal (LOS), and current antenna azimuth and elevation figures. The computer updates all this information every minute until LOS.

If the high-speed graphics routine is selected, the computer performs basically the same operations as the real-time routine except that the speed of the updating is increased.

If the choice is made to display antenna direction data, then the Apple displays the azimuth, elevation, and associated time of day for each minute the satellite is in range.

The choice to display SSP data displays the time after EQX, time of day, and longitude and latitude of each SSP for each minute of the orbit.

The choice to display all orbits will display the same list of data for all the orbits for the day selected.

If you choose to compute another orbit, the program retains all satellite parameters and displays the orbit list, allowing the operator to select another one of the orbits for that day.

Choosing to restart clears all variables and starts the program over from the beginning.

Finally, a choice to quit will do just that, stopping the program immediately.

Program Structure

This program is constructed of fifteen separate software modules, each with a specific job as indicated below.

1000 Initiates all variables, arrays, constants, and functions.

2000-4000 Main routine.

5000 Determines the mode of operation for OSCAR 7 or 8. (OSCAR 7 is now out of operation, of course.)

1) Subpoint latitude

$LAT = \arcsin[\sin(Inc)\cdot\sin(360T/PER)]$

T = time after EQX

PER = period time

2) Subpoint longitude (Earth rotation is .25T)

$$LON = \arccos\left[\left(\frac{\cos(360T/PER)}{\cos(LAT)}\right) + (.25T) + L_{EQX}\right]$$

L_{EQX} = longitude at EQX

3) Distance from station to subpoint

$DIST = \arccos[(\sin(A)\sin(B) + \cos(A)\cos(B))\cos(L)]$

A = LAT of first point (station) (+90° to −90°)

B = LAT of second point (SSP) (+90° to −90°)

L = LON of first point − LON of second point

DIST units is in great circle arc degrees radians

4) Bearing from station to subpoint

$$BNG = \arccos\left[\frac{\sin(B) - \sin(A)\cos(DIST)}{\cos(A)\sin(DIST)}\right]$$

If L in formula 3 was negative then the bearing = 360° − BNG

5) Elevation to satellite

$$ELEV = 90 - \arctan\left[\frac{H \times \sin(DIST)}{H \times \cos(DIST) - 3957)}\right]$$

H = Earth radius + satellite altitude

6) Distance to satellite

$$RNG = \left[\frac{H \times \cos(DIST) - 3957}{\cos(90 - ELEV)}\right]$$

RNG is in statute miles

7) AOS/LOS range (horizon of satellite)

$$D = \arccos\left(\frac{R}{H}\right)$$

R = Earth radius (3957 miles); D is in great circle degrees

8) $$PER\ time = \left(2\pi \times \sqrt{\left(\frac{(H)^3}{9.56 \times 10^4}\right)}\right)/60$$

PER is in minutes

9) $$Precession\ of\ Earth\ per\ orbit = (PER \times .25)^\circ \left(\frac{360^\circ}{1440min}\right) = .25$$

10) Orbits per day = 1440/PER

Fig. 2. Formulas.

SD(1) = station latitude
SD(2) = station longitude
RC%(1,36) range circle plotting points; RC%(0,X) = Y coordinate; RC%(1,X) = X coordinate
AE(0) = orbit#; AE(1) = time of EQX; AE(2) = EQX longitude
AF(2,B) data for orbits for the day requested
AF(0,X) = orbit#; AF(1,X) = time of EQX; AF(2,X) = EQX longitude
B = no. of orbits per day
SSP(5,PER) = subsatellite point data for orbit
SSP(0,X) = time of day; SSP(1,X) = LAT; SSP(2,X) = longtitude; SSP(3,X) = distance
SSP(4,X) = azimuth; SSP(5,X) = elevation
PER = satellite orbital period in minutes
X—denotes each minute of orbit
Latitude & longitude are in radians
Distance is in great circle radians
Azimuth and elevation is in radians
L%(53) map latitude to Y coordinate-conversion constants
MC%(1,53) = satellite path plotting points
MC%(0,X) = X coordinates
MC%(1,X) = Y coordinates
D1$ to D7$ = days of week D1$ = "SU"; D2$ = "MO"; etc.
M1$ to M5$ = OSCAR operating modes
AS(1) = time of acquisition of signal (UTC); AS(2) = time after EQX(min) for AOS
LS(1) = time of loss of signal (UTC); LS(2) = time after EQX(min) for LOS
TR = time in range (LS(2) − AS(2))
AG = selected orbit
R1 = 1.5708; R2 = 3.14159; R3 = 4.7124; R4 = 6.2832; R5 = 57.296; R6 = .01745; R7 = 3957; R8 = 1440; R9 = 111.12
MO$ = OSCAR mode of operation—made up of M1$ to M5$
DA$ = day of week
DT$ = date of orbit (MM/DD/YY)
OS% = satellite selected
OS$ = satellite name
ALT = satellite altitude in statute miles
INC = satellite orbit inclination (in radians)
C = satellite precession degrees per orbit (in radians)
D = satellite horizon (in great circle radians)
D$ = control (D for DOS)

Fig. 3. Variables, arrays, and constants used in OSCAR Pathfinder.

6000 Lists the orbits and EQX data for all orbits of the day.
7000 Computes SSP data. This is the main math routine. It computes the time of day for each point, stored in array SSP(0,I); latitude, stored in SSP (1,I); longitude, stored in SSP (2,I); distance from station to subsatellite point, stored in SSP(3,I); and true bearing from station to subsatellite point, stored in SSP(4,I) for each minute of the orbit. It checks to see if the satellite is in range and, if it is, it computes the elevation, stored in SSP(5,I), and sets up pointers to AOS and LOS time. "I" in the arrays corresponds to the time in minutes after EQX. The subroutine also checks to see if the satellite path will take it within the bounds of the map and, if it does, it sets up pointers to when it enters and leaves the map bounds (YA and YB). Finally, it computes the time in minutes that the satellite is in range.
8000 Used to input reference orbit data: orbit number, time of day of EQX, and EQX longitude.
9000 Computes X,Y coordinates for the range circle to be displayed on the map.
9500 Draws the range circle on the map.
10000 Draws the satellite path on the map.
10500 Computes X,Y coordinates for drawing bearing lines from station location to each SSP. Stored in MC%(0,I) and MC%(1,I).
11000 Converts longitude and latitude figures to X and Y coordinates.
12000 Converts time in the form of hours, minutes, and seconds to the form of minutes after midnight.
12500 Converts time in the form of minutes after midnight to hours, minutes, and seconds.
13000 Accepts data needed to compute orbit data for satellites other than OSCAR. Satellite altitude, inclination, and name must be entered.

The formulas used in these routines are detailed in Fig. 2. The major arrays and variables being used are detailed in Fig. 3.

Have Fun!

I hope you can make some use of this program as I have. I have been using it regularly to predict OSCAR positions and I've also used some of the techniques in other programs.

If you really want to get OSCAR Pathfinder running with the least amount of effort, you can send me $15 and I'll ship you a disk with everything on it ready for turnkey operation. If you have any questions that I haven't answered here, send me an SASE and I'll see if I can help you out. Have fun! ■

Which TVRO Antenna Is Best?

—Satellite Central, part IV

In the past few months, I've received dozens of letters from hams wanting to know which antenna is best. Since it's easy to get stung, you must know what to ask for and, in many cases, to demand!

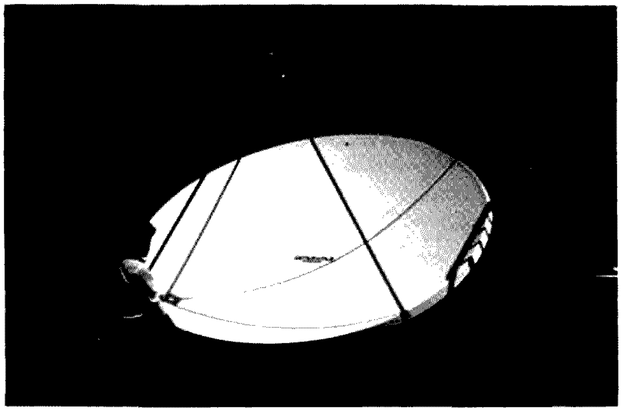
The $100 Receiver!

December's mail was heavy, mostly due to my mention of the $100 receiver design by Rex Roads. Well, Rex is busy cleaning up the drawings and we have a complete construction article planned for late spring. In the meantime, start looking for a site for your $100 dish. We've got one of those coming, too.

Let's cover the kinds of antennas you'll likely find in TVRO service and then move on to selection tactics in my next article. All things considered, you need about 40 dB antenna gain at 4 GHz for domestic birds, with more gain necessary as you move off the prime coverage footprints.

The situation is aggravated by the need to shield the antenna from noise on all sides except the main lobe. Down in the dc bands, antenna side-lobe response is usually something you ignore unless you want maximum efficiency or enjoy climbing the tower to prune beam elements! You must pay attention to this problem in TVRO work because the signals you want are well below the terrestrial noise floor in the vicinity of the antenna. Typical signal levels are 30 dB *below* the surrounding noise. It's like trying to hear a normal conversation in a room full of people shouting at you! More gain won't help.

The solution is to build a dish reflector large enough to produce a very narrow beamwidth. Then use some plumbing in the form of a feedhorn to channel the signal to a shielded monopole antenna probe. Several antenna designs can be used. All of them work, but you must study them carefully.



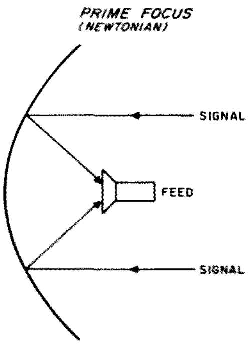


Fig. 1. The prime-focus design uses a parabolic reflector to concentrate the signal from the satellite into a small area known as the focus point. The accuracy of the dish surface to a true parabolic curve governs the size of the focus point and placement of the feedhorn.

A Tempting Menu of Dishes

Fig. 2. The Cassegrain or twin-reflector design offers increased efficiency, but there are limits. As a rule, Cassegrains must be larger than ten feet before you can derive any benefit because the subreflector blocks a significant portion of the signal from ever reaching the dish.

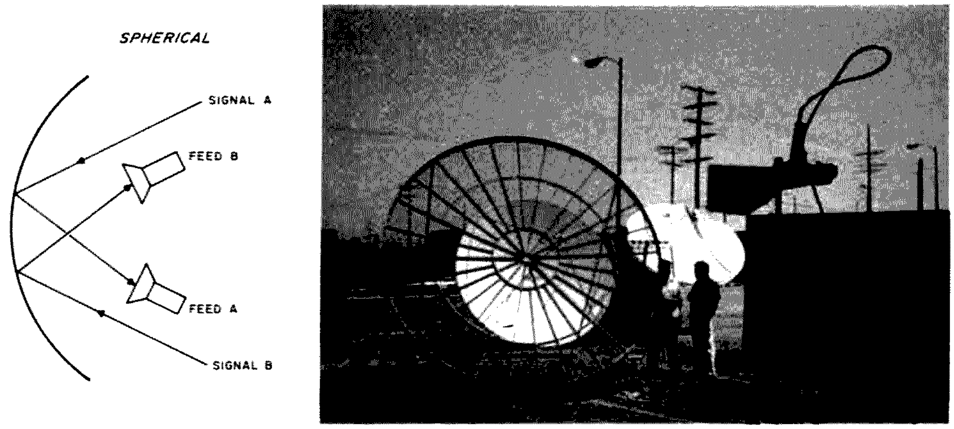

Fig. 3. Carve out a piece from a very large metal ball and you have the spherical antenna. It is possible to receive several satellites at once using separate feeds or you can simply mount the feed and LNA on a tripod and move it from satellite to satellite.

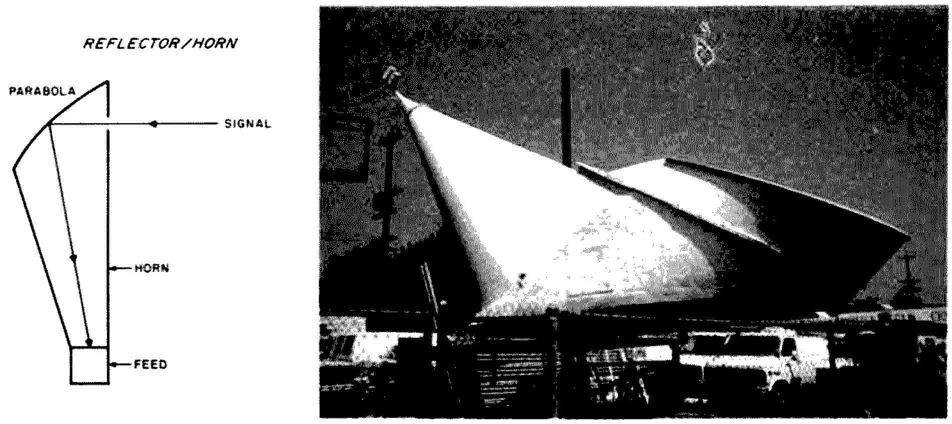

Fig. 4. The horn/reflector antenna is just a segment of a parabola fed by a very long horn. It has been in use for many years by A.T. & T. and other terrestrial microwave users. This design is considered by many as the ideal solution to high gain and low side-lobe response.

The prime-focus design seen in Fig. 1 is by far the most popular TVRO antenna today. The surface is formed into a parabolic curve so that the reflected signal travels the same distance to the focus point where it enters the feedhorn opening. The distance from the reflector to the focus point is referred to as the focal length. The formula for a parabola is available out of many trig or calculator instruction books. It is easy to apply the formula to a wood or masonite template and to build a working dish from wood and window-screen material in a few evenings. Prime-focus dishes are simple to build, and they may have very good side-lobe properties if you are careful with construction and feed selection.

Next, we have the Cassegrain, or two-reflector, dish seen in Fig. 2. Most commercial satellite stations use this design because overall efficiency can be improved by additional contouring of the hyperbolic subreflector and, in some cases, modifying the curve of the main reflector. Cassegrains can have very good directivity and may, with very special design, achieve low side-lobe response as well as greater gain than equivalent-sized prime-focus models. This slight advantage is due in part to the longer focal length and reduced area presented to the feed.

Building a Cassegrain may be harder because you now have two reflectors that must be in perfect alignment before the signal can reach the feed. That is, the focus point of the main reflector (parabolic) must coincide with the back focus point of the subreflector (hyperbolic). As a rule, Cassegrain subreflector sizes are between 10 and 20 percent of the diameter of the main reflector, but the main reflector must be larger than ten feet before you can derive any benefit. So the subreflector presents a real problem since it blocks a significant portion of the signal from ever reaching the dish! This phenomenon is known as aperture blockage and is the one factor that keeps the Cassegrain from becoming popular in dish sizes below 4 meters.

Perhaps the most interesting style in use today is the spherical antenna. The late

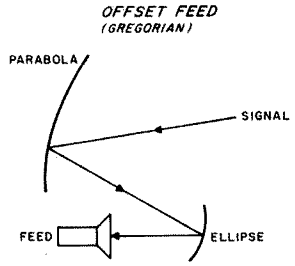

Fig. 5. The offset feed dish is similar to the Cassegrain in the two-reflector configuration, though single-reflector versions are also used. Side-lobe response is greatly improved because of a lack of aperture blockage.

Oliver Swan developed a practical approach to this design. The spherical holds the unique advantage of being able to receive several satellites at once—but separate feeds are required, as shown in Fig. 3. It is possible to place a spherical so that it can see almost a 40-degree arc of the Clarke belt. Then you simply move the feed in an arc to move from satellite to satellite.

The spherical looks almost like a flat plate or a very long focal length parabola. Mere inches keep either statement from being true. Despite the hassle of poor side-lobe response, the spherical offers an easy way for the home constructor to get his antenna built at minimum cost. Instead of using a parabolic curved template, one simply uses a wire stretched from some distant radius point to adjust and check accuracy.

Ma Bell, on the other hand, has a lot of experience with 4-GHz signals. Her horn/reflector, or Hogg horn (named after one of the inventors), is shown in Fig. 4. This design embodies high gain and excellent side-lobe response. It's just about the only style that will work in a metropolitan area where interference is rampant. Unfortunately, the Hogg is a beast to mount! A typical 4.5-meter-aperture unit may have an overall length of 34 feet. Your backyard has got to be very large or else the barbecue must go!

Fig. 6. Nearly ideal reflector surfaces are possible when flame-spraying is applied to fiberglass dishes. Care must be used in the coating as well as curing time for the resin to ensure that the dish will follow the proper curve within 1/8 inch.

Another design used in commercial applications is the offset parabolic seen in Fig. 5. The feedhorn does not get in the way of the signals, thus improving the gain and reducing side lobes. The modified torus is finding use in cable TV and military installations where several signals may be needed with about equal efficiency. Each design has its own unique advantage and price tag!

What Materials Work For Dishes?

Just about any reflective surface will work, but some obvious concern can develop when you look at a fiberglass dish. Some designs use mesh or sheet-metal reflectors imbedded in the fiberglass. Others may use a metal film applied by a technique known as flame-spraying—as seen in Fig. 6. Flame-spray may improve the accuracy of the dish geometry, but there is no easy way to know how well the coating was applied. It's easy to get sloppy. I've tested dishes where large sections had no reflective properties at all!

On the other hand, a dish constructed of mesh screen may not follow a parabolic or spherical curve over the entire surface. This is especially true of window-screen designs. The mesh bends easily and must be applied in flat sections. Despite the claims of many manufacturers, a flat section cannot possibly work as well as one which follows a parabolic or spherical curve. Why, then, do some mesh dishes work? The secret is simply in the number of sections used. More sections come closer to the overall desired curve. Interestingly enough, gain loss is not the big problem with window-screen designs. Using fewer sections affects the side-lobe response of the dish more than it does the gain!

How big can the holes in the mesh be? Good question. Logically, they must be big enough to appear as a reflective surface to the wavefronts. If we go back to the books, we can think of the holes as waveguides beyond cutoff and simply make them progressively smaller until microwaves don't slip through. The bottom line is about 1/8-inch-diameter holes. Anything larger does not reflect nearly as well.

Solid spun-metal dishes are by far the best. Their accuracy and reflective properties outweigh their unwieldiness. The only catch is that large spun dishes are nearly impossible to find. The surplus market top-ends at the ten-foot mark.

The next best bet in materials is metal petals. They reflect just as well as anything else, but you must use care during assembly or they may not accurately follow the dish curve. Bending, twisting, and sweating are normal occurrences when you try to put one of these types together!

What About Feedhorns?

Fig. 7 shows some typical feedhorns. Their primary purpose is to efficiently couple most of the signal bouncing off the reflector into the LNA. But therein lies the problem and perhaps the first place you may want to try to improve basic TVRO-antenna design. You see, the feedhorn, like the dish, has its own sensitivity pattern, too. Like any antenna, they are most sensitive on axis, tapering off at the sides. The key to feed efficiency is in the taper. Remember, we want to receive a signal that is well below the terrestrial noise floor. And the feed overshoot seen in Fig. 8 would indeed intercept the noise we want to reject.

So what do you do if all feeds overshoot? The trick is in finding a happy medium of gain and efficiency versus noise intrusion. Let's assume for the moment that the feed is designed to taper off sensitivity so that the edges of the main dish reflector just intercept the 10-dB points on the feed pattern. Visualize the situation where the feed is most sensitive to signals bouncing off the center of the reflector, but less sensitive to signals at the edges. This problem has kept feed designers working in the wild quest for the ideal curve seen in Fig.

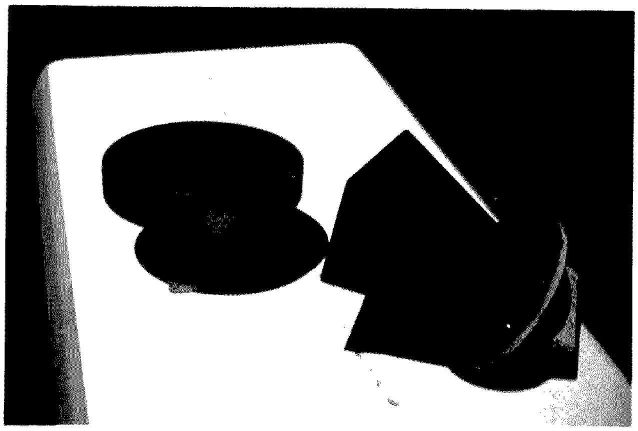

Fig. 7. Feeds may take on various shapes, but their sole purpose is to properly illuminate the dish. I had a chance to test several of the feedhorns sold today. My spectrum analyzer showed a drastic difference in gain and efficiency on my particular dish, so feed matching to the dish is important.

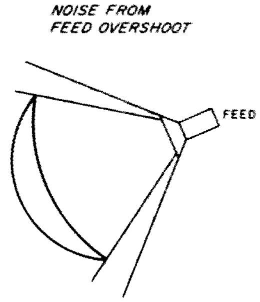

Fig. 8. Better efficiency achieved by a broader feed beam will only cause overshoot and increase intercepted terrestrial noise. The best compromise is about a 10-dB drop at the edge of the dish. A metal shroud around the rim of the dish can block some noise seen by the feed.

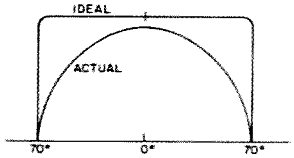

Fig. 9. Typical feed-pattern sensitivity just covers the dish at the 10-dB points. This means that the dish is less efficient at the edges. Nearly 100 percent antenna efficiency would be possible if you could achieve the ideal curve and still eliminate feed-phase taper, aperture blockage, and reflector-surface errors.

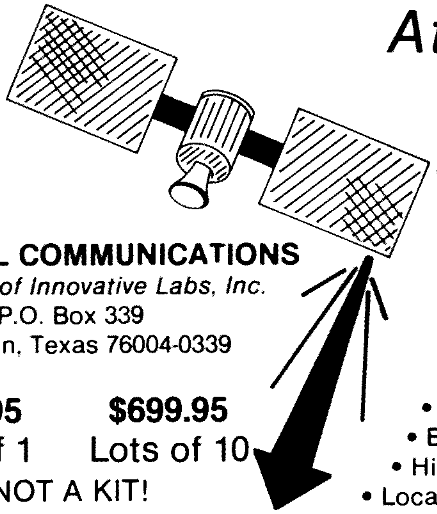
9—one that tapers off like a steep ledge rather than a rolling hill.

Perhaps the most interesting outcome from recent feed design advances has been the radical departure from the classic flared waveguide approach. Look at any dish and you will realize that because the dish is circular, the wavefront reflected into the feed will be also! So "circular-to-waveguide" transitions in feed are becoming the rule rather than the exception.

This deviation from the classic rectangular feed can boost overall antenna efficiency to nearly 60 percent. Is that all? Higher efficiency is possible and, in fact, within reach if you can make better use of the surface near the edge of the dish. The two-reflector, or modified Cassegrain, design is a step in that direction. But the problems of proper amplitude illumination and equal phase paths over an unobstructed reflector aperture are still there. For the moment, it appears that matching a feed to a dish is like fitting a round peg in a square hole. A hammer won't help! ■



At last, an inexpensive, state-of-the-art satellite TV receiver

MODEL DL-2000

- Fully tunable audio with AFC
- Channel scan feature standard
- Remote control option available
- Jack for external signal metering
- LED bar readout indicates video quality
- Front panel selection of video polarity
- Built-in RF modulator and video output driver
- High quality construction, attractive packaging
- Local oscillator leakage minimized special mixer design

Home-Brew a TVRO Downconverter

—works with last month's LNA

J. Richard Christian WA4CVP
Rte. 1, Box 209W
Creola AL 36525

S.F. (Mitch) Mitchell, Jr. WA4OSR
PO Box 973
Mobile AL 36601

If you liked our low-noise amplifier article in the February, 1982, issue of *73* ("Job's Own LNA"), you will love our no-alignment downconverter.

This downconverter can be built by an average technician and the parts are readily available. The local oscillator (LO) and the mixer are commercial units manufactured by Magnum Microwave Corporation of Sunnyvale, California. The design features a dc block for feeding power to your LNA, and it can be built for less than $225. With this downconverter, an LNA, and a good antenna, you can receive noise-free pictures from the satellites.

The converter takes the 3.7-to-4.2-GHz signal from the LNA and converts it to a 70-MHz i-f signal. The design features single conversion for simplicity and ease of duplication. The local oscillator is voltage-tuned, and there is no alignment required. You put the parts on the board, mount it in the box, power it up, and watch the birds! How simple can you get?

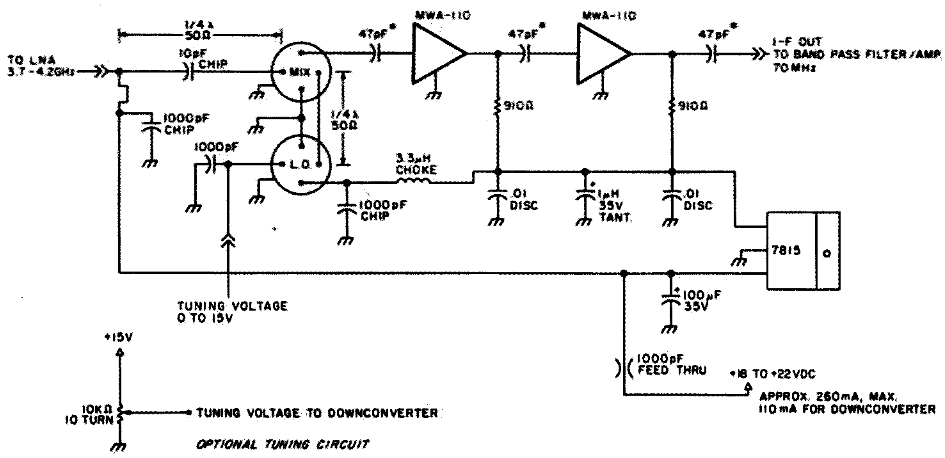

*Fig. 1. Satellite downconverter schematic. * = chip or disc ceramic.*

Circuit Description

Refer to the schematic, Fig. 1, and to the PC-board layout and parts placement overlay for the following discussion. The complete downconverter is constructed on a 2" by 4" teflon PC board, 1/32" thick. Impedance matching is achieved by using microstrip transmission lines. To supply dc power for the LNA, a dc block is incorporated on the board. This lets the coax from the LNA supply the LNA's required operating power. The dc feed is accomplished very simply by supplying the +18 to +22 volts that powers the downconverter to the rf input through an rf choke. The dc side of the choke is bypassed for rf with a 1000-pF chip capacitor.

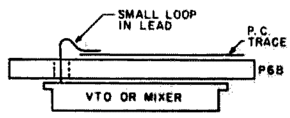

Fig. 2. Mixer and vto lead bending and soldering instructions.

The 4-GHz input is ac-coupled through a 10-pF chip cacpacitor to a ¼-wave, 50-Ohm transmission line going to the rf port of the mixer. Local oscillator injection to the mixer is also via a ¼-wave, 50-Ohm transmission line for impedance matching. The i-f port of the mixer is ac-coupled to the first MWA-110 for approximately 14 dB of i-f gain, and then to the second MWA-110 for an additional 14 dB of i-f gain. The output of the downconverter feeds the 70-MHz bandpass filter in our home-brew receiver.

Construction

The first step in constructing the downconverter is to drill the 2" by 4" minibox using the drilling guide shown in Fig. 3. The bare PC board can also be used as a drilling template. Use ½" standoffs to mount the board in the box. We used a type-N connector for the rf connection from the LNA. You also can use an SMA connector in place of the type-N with equally good results. BNC or type-F connectors are adequate for the LO tuning voltage and 70-MHz i-f out.

Next, install the two MWA-110 i-f amplifier ICs on the printed-circuit board. Be sure that they are flat against the ground-plane side of the PC board. Solder the tabs on the 110s to the ground plane, cut the leads to 1/8", bend them flat against the PC board, and solder. Now install the mixer and local-oscillator modules. Be sure that the ground pins are in the correct holes on the PC board, or you will wind up with some expensive but useless trinkets.

Caution: Do not cut the pins on the modules. Bend the pins in a small loop over to the PC board and solder. (See Fig. 2.) Solder the pins to the PC-board trace using as little solder as possible. Install and solder the six feedthrough jumpers, using pieces of cut-off resistor leads, and solder on both sides of the board. Now install the rest of the components, except for the 3.3-uH choke.

After construction is complete, check for solder bridges. Temporarily connect the +18 to +22 volts to the dc input of the voltage regulator. Measure the output voltage to see that the voltage regulator is working. The output should be +15 volts. Measure the voltage drop across the 910-Ohm resistors; it should be 2 to 3 volts. If it's not within the range, then you probably have a bad MWA-110 (we have found several). If the voltage drop measures OK, remove power and discharge the electrolytic capacitors. Now install the 3.3-uH choke. This completes the PC-board assembly. The next step is to install it in the minibox.

Depending upon the type of rf connector used, N or SMA, it may be necessary to solder extension leads to the PC-board pads to reach the connectors. Be sure that when the extension leads go through the PC board they do not short out to the ground-plane side. Solder the four leads (three from the connectors and one from the 1000-pF feedthrough capacitor) to the appropriate points on the PC board as shown by the parts overlay.

> **PC BOARDS**
>
> Etched and drilled teflon printed circuit boards for the downconverter are available for $27.00, plus $1.50 for handling and postage, from Martcomm, Inc., PO Box 74, Mobile AL 36601.

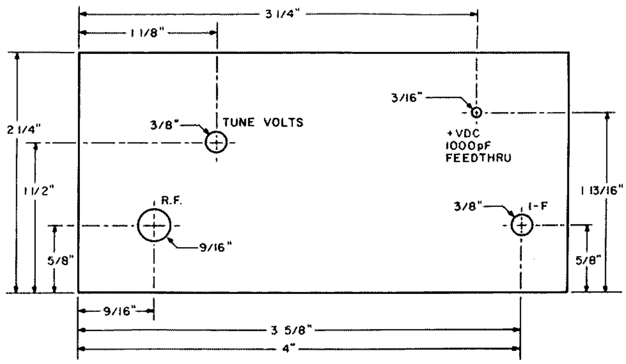

Fig. 3. Drilling template for 2" by 4" minibox.

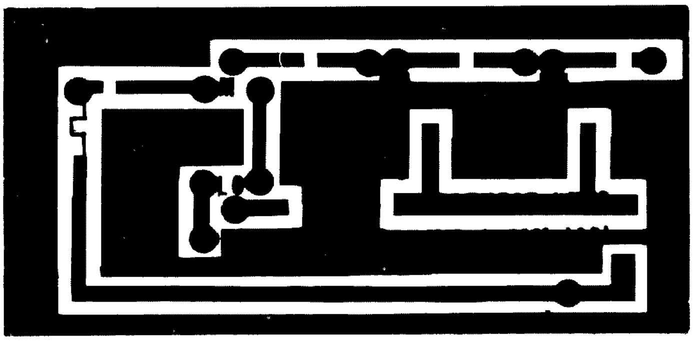

Fig. 4(a). Foil side view of board.

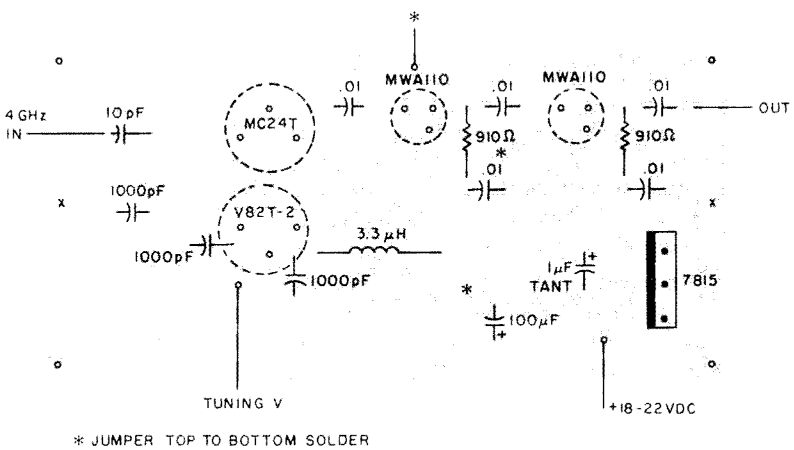

Fig. 4(b). Parts placement, foil side view.

Checkout

If your antenna and LNA have been completed, you will be able to check your system through the i-f output of the downconverter. With your LNA and downconverter connected to your antenna, apply power. Connect the output of the downconverter to the antenna terminals of a *conventional* color-TV receiver, with the TV tuned to any unused low channel between 2 and 5. If possible, connect a voltmeter to the agc line on the TV set tuner. The agc voltage can give a very useful indication of proper aiming and adjustment of your satellite TV antenna.

With the optional tuning circuit (Fig. 1) connected to the tuning voltage input of the downconverter, transponder 1 tuning voltage will be about 4 volts. To tune transponder 24, you will need about 12 volts. You should be able to tune in most transponders over the 4-to-12-volt range. Also, you should get an indication of video on the color-TV set when a transponder is tuned in. The video will be of very poor quality since the satellite signal is frequency modulated while the conventional terrestrial TV signal is amplitude modulated. You should still be able to recognize the pictures, however. Sync will be very critical and you probably won't be able to sync on all transponders.

That's it! The rest of your TVRO receiver is cheap and simple, as we will show you in future articles. ■

Parts List

Quantity	Description
1	MC24T mixer module (Magnum Microwave)
1	V82T-2 local oscillator module (Magnum Microwave)
1	10-pF chip capacitor
2	1000-pF chip capacitors
3	50-pF disc ceramic capacitors
2	.01 disc ceramic capacitors
1	1-uF, 35-V tantalum capacitor
1	100-uF, 35-V electrolytic capacitor
1	1000-pF feedthrough capacitor (mounted on minibox)
2	910-Ohm, ½-Watt resistors
1	10k-Ohm, 10-turn pot (optional tuning circuit)
1	3.3-uH choke
2	MWA-110 ICs
1	7815 voltage regulator
1	2" by 4" minibox
	Rf connectors, hardware, etc.

The Magnum Microwave MC24T mixer module, the V82T-2 local oscillator module, the MWA-110s, chip capacitors, and the rf connectors are available from Cliff Jones at Alaska Microwave, 4335 East Fifth Street, Anchorage AK 99504, (907)-338-0340, a regular *73 Magazine* advertiser.

Acknowledgments

We would like to thank the staff at Magnum Microwave for running tests on our prototype downconverter. The measured down-conversion gain was 21 dB with 4-GHz input. At −20-dBm and −40-dBm input, the second harmonic of the 70-MHz i-f was −25 dBc and −50 dBc, respectively. Magnum also confirmed our discovery that the MWA-110 will oscillate if not properly grounded. The above specs were furnished to us by Magnum Microwave and are quoted with their permission.

WOULD YOU BUY A SATELLITE ANTENNA SIGHT UNSEEN?

ONLY FROM HASTINGS ANTENNA CO.!

WE NOW CAN OFFER YOU THE BEST 10 FT. (3.0M) ANTENNA ALSO.

Our 3 Meter Antenna has all the features you want:

- **Casse Grain Feed System using a Chaparral Super Spherical Feed Horn and Spun Hyperbolic Sub-Reflector.**
- **24 Petals (Aluminum .060 Gauge ¾ Hard) Baked on White Finish Both Sides.**
- **Polar Mount with Programmable Offset for True Tracking. (It's not a True Polar if it doesn't have this feature).**
- **Engineered for High Strength and Light Weight, cutting your Freight Cost Drastically.**
- **Added Security for your LNA and Down Converter.**
- **Low Cost with Dealer Oriented Pricing - Call or Write.**
- **Suggested Retail Price $1595.00.**

The Bottom Line, We'll Pay the Freight on all One Lot Price Orders in the Continental USA. Free Freight Subject to Change.

TVRO Q & A

—advice from WBØPOP

Ken Rae WBØPOP
737 South Clarkson
Denver CO 80906

I want to build a TVRO. What is the first step?

Most people get started by acquiring an antenna. You can buy a commercial antenna or you can build your own dish. If you buy, plan on spending $1000 or more. Building your own is cheaper, but it can take considerable time and energy. Plans are available from several sources, but don't expect to get a world of information from a $10 brochure. It takes a lot of research and study since there is no one source for all the information you need.

How can I get a picture for the lowest possible cost?

If you are not concerned about the quality of the picture, then all you'll need is an antenna, a low-noise amplifier (LNA), a mixer, and a conventional television receiver. With just these components you'll be able to say that "I received satellite TV." Since the TV receiver acts as a slope detector, the video will not be clear or stable, but this low-cost approach will get you started.

What about kits?

Kits are available for each part of an Earth terminal, but the best way to describe this part of the industry is "buyer beware." Try to find someone who has successfully completed the kit before you take the plunge.

What size dish do I need?

The size of antenna depends on the quality of the LNA, the strength of the satellite "footprint" in your location, and the desired signal-to-noise ratio. You can get watchable video from an eight-foot dish, but the 10-foot dish seems to be the industry standard for home TVROs.

Why are 10-foot antennas so popular?

A 10-foot dish is usually the minimum size that is practical for receiving good quality pictures in most locations in the US. You can use a smaller antenna, but the need for a better quality LNA may boost the overall cost higher than what you would spend for a 10-foot system.

What is the smallest dish I could use?

If you are willing to settle for audio only, a four-foot diameter antenna supposedly works. A six-foot antenna might give you a faint video image if everything else is perfect.

How much should a 10-foot dish weigh?

At one extreme there is an umbrella-type antenna that weighs only 22 pounds. On the other end of the scale there are heavy-duty antennas that weigh half a ton or more. The average weight of a fiberglass or spun-aluminum dish is in the neighborhood of 200 pounds.

Should I get a spherical or parabolic antenna?

The parabolic is my choice because it's versatile. You can sweep the antenna across the sky, making it easy to change to a new satellite. The spherical is a good antenna from a construction viewpoint. Unfortunately, changing satellites involves moving the feedhorn, which is usually six to eight feet above the ground.

Someone told me that I should build a spherical dish because it exhibits more gain than a parabolic antenna. Is this true?

The gain of spherical antennas is indeed greater because the dish has a flatter surface. However, the flat curvature means that the spherical will pick up more unwanted noise. The parabolic has slightly less gain but more noise immunity. You must consider both noise and gain characteristics when choosing an antenna.

How can I tell if a dish is a parabolic or spherical?

A parabolic dish will tend to look flatter as your eye moves toward the edge. The spherical antenna has a constant curve, rounded all the way to the rim.

I found a surplus dish. How can I tell if it is too deep or too flat?

You want to check the focal-distance-to-diameter ratio, F/D. You can find the focal point by using the equation $D \times D/(16 \times H)$, where D is the diameter and H is the depth. The F/D should be between 0.35 and 0.55 with 0.4 being about best. Ratios out of this range will not have the optimum noise versus gain characteristics.

I have found a dish but it has some dents and holes. Will that affect the performance?

A 10-foot dish has approximately 78 square feet of reflective surface area, so a few imperfections won't cause a problem. You probably can afford to lose as much as 5% of the surface area.

How smooth does the surface of the dish have to be?

The accuracy of the antenna should be plus or

minus a sixteenth of an inch of the parabolic curve if you expect a reasonable level of gain.

I am trying to choose between buying a 10-foot dish made for TVRO work and a surplus 16-foot antenna. The price is about the same; wouldn't the 16-footer be a better deal?

It depends upon their quality. Often a surplus dish that was not designed for use with 4-GHz signals will be inferior to a smaller, better constructed antenna. Check the surface accuracy of both antennas. Anything more than an average inaccuracy of an eighth of an inch means that gain will be adversely affected. If the big dish meets the requirements for 4-GHz operation, then by all means grab it.

How important is the structural strength of a antenna?

A dish that can stand on its own rim and still hold the parabolic shape within an eighth of an inch is not likely to be harmed by weather. Anything weaker is questionable.

The area I live in has a lot of wind. What can I do to avoid losing my antenna?

To avoid having an airborne dish, I fastened a cable around the rim and attached it to a deadman anchor.

Screen antennas seem easy to build. How large can the holes in the mesh be?

A quarter-inch hole is about the largest gap you can have without an appreciable amount of the signal feeding through. An eighth of an inch is a good choice. Window screen can be used, but it does have a lot of wind resistance.

Is it necessary to solder every joint in a screen reflector?

If the sections of mesh or screen overlap each other by at least one wavelength (approximately three inches), the seams will not cause a dead spot. If there is not enough overlap, there should be some sort of electrical bonding.

What do trees and shrubs do to the satellite TV signal?

Foliage acts as a sponge that absorbs microwave signals, and it generates noise that will be picked up by the antenna. Trees and shrubs have a destructive effect and should be avoided when you choose a site for the antenna.

What effect do rain and snow have?

Precipitation doesn't seem to have much effect on a 4-GHz signal—perhaps half of a dB at most. If the moisture gets inside of the electronics, there can be significant attenuation. Powdered snow can pile up in a dish without causing a problem. But if the snow melts and refreezes, the surface of the dish can be distorted, causing the signal strength to drop. You should keep your antenna clear of ice and snow.

My neighbors complain about the appearance of my TVRO antenna. Can I cover the dish without adversely affecting the signal?

A thin covering of plastic or fiberglass can be used without too much signal attenuation. Avoid a covering made from wood or other material that contains moisture.

Will my dish work inside a barn or garage?

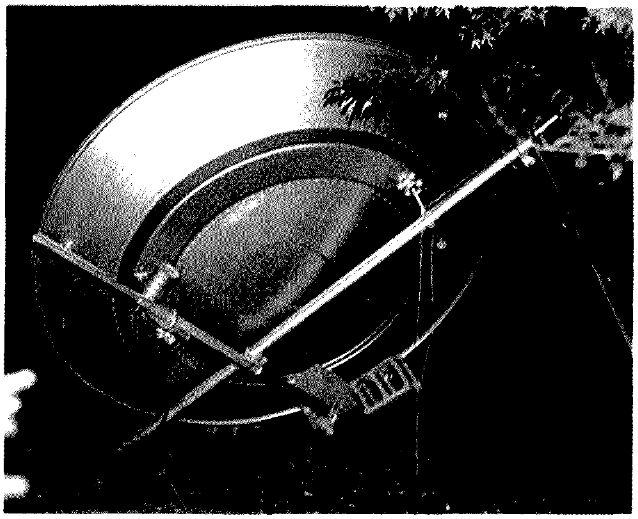
Yes, you can keep the antenna inside. Of course, the building will attenuate the signal. The exact amount of the loss depends on the type of building; it can be anywhere from two to six dB of attenuation.

I bought a used metal dish and want to paint it. Any suggestions?

Aluminum antennas can be painted with a good grade of latex house paint intended for house siding. Be sure to use a light color. Painting the dish black will result in the antenna absorbing heat, stressing the dish and changing the shape. The texture of the surface should be dull and flat, not shiny, since we want the light to be diffused instead of reflected towards the LNA. Follow the same guidelines for painting a wooden or fiberglass antenna.

How far above ground should I mount my dish?

The rule of thumb for dish installation suggests that the lowest edge of the dish should be located two or three feet above the ground. Setting the antenna directly on the earth will increase the amount of noise that enters the system.■



I used readily-available materials to build this simple, yet effective, mount for my satellite TV antenna.

Indian Hams Rejoice
—import restrictions lifted

Indian hams have achieved a breakthrough in their efforts to solve their problems of lack of equipment. The manufacture of communications equipment in India is the monopoly of the public sector (government-owned industries), which is itself lagging so much in production that it is unable to fully meet even the needs of the governmental users.

For several years, the Federation of Amateur Radio Societies of India had been making representations to the government, requesting relaxation of import controls without much success. The improvement in the foreign exchange position enabled the government to make concessions to certain users—among them scientists and professionals—who were allowed to import equipment valued at up to 10,000 rupees (about $1200 US) for their personal use. M.V. Chauhan VU2MV, Hon. General Secretary of the Federation, saw an analogy between the scientists and the hams. He convinced the Electronics Commission that the extension of similar privileges to amateurs was the only solution to the equipment problem.

Disaster can sometimes have a beneficial fallout. The communications link set up at Morvi by our hams (led by Saad Ali VU2ST, president of the Federation, Jimmy Mistry VU2IJ, and Vasant Bhat VU2RX) after a bursting dam had killed an estimated 30,000 in the span of a few hours cleared any lurking doubts in the mind of the government about the utility of ham radio to the nation.

Relentless representations to the various ministries by the Hon. General Secretary Chauhan and President Saad Ali finally resulted in the inclusion of radio amateurs in the category of scientists, and they were allowed the privilege of importing, under Open General License, test equipment worth up to 10,000 rupees in a year. There were more representations, and the momentous decision was announced which permitted the import of "amateur radio communications equipment, including kits, accessories (including antenna rotator motors, feedlines, standing wave ratio bridge), instruments, spares, and components" up to 10,000 rupees in a year, without the need for a formal license.

The Federation of Amateur Radio Societies of India is today a tower of strength to the Amateur Radio Service in India. Its QSL bureau handles the bulk of incoming and outgoing cards. *Radio,* the monthly journal of the Federation, edited by M.V. Chauhan VU2MV, is read by virtually every ham and SWL. The ARRL *Handbook* and other books have been imported and sold at a low price. A guide to amateur radio in India by Saad Ali has been published. The Federation's efforts have led to a breakthrough in making equipment available to Indian hams.

The Federation is not resting on its laurels. M.V. Chauhan is continuing his efforts to have the manufacture of ham equipment thrown open to private industry, so that equipment can be made available to the less affluent ham for prices expressed in hundreds of rupees rather than in thousands, which is the case with imported equipment. He believes another breakthrough is on the way, which will help amateur radio in India to become the hobby of the common man and not a monopoly of the affluent. ■

Licensing for Americans Overseas

—classes help, but our government doesn't

In an earlier issue of *73 Magazine*, Wayne Green mentioned that he would like to hear what the amateur radio community was doing to get more people into the classrooms and on the air. At first, I thought of sending a letter to *73 Magazine* describing our current situation here in West Germany involving military personnel in regard to licensing classes. After pondering the idea for a few days, I decided that an article would be more appropriate.

The not-yet-licensed American civilian or military person abroad will, in many cases, encounter some problems that are unique, to say the least. But being a ham in the military has many advantages, such as the opportunity to operate from various countries of the world with reciprocal licensing. Unfortunately, getting that US license once an individual has been sent to a far corner of the world is sometimes difficult. But for those who are interested in obtaining their ticket, there is hope. Thanks to a crop of dedicated and hard-working hams scattered throughout worldwide military installations, amateur radio licensing classes are a reality.

Before I tell you about amateur radio classes and the people who teach them, let's take a look at why these individuals who aren't licensed desire their ticket. Actually, their reasons are no different than anyone else's. Basically speaking, they have a genuine interest in amateur radio. However, there are some underlying reasons which motivate these prospective hams.

First of all, it is a fact that a large number of newly licensed hams in the United States were once active on 11 meters. West Germany, like other countries in Western Europe, has a personal communications band on 27 MHz. Quite a few Americans come to Germany with their CB gear only to discover, to their dismay, that it's just as bad or even worse than back home. There are fewer channels, lower allowable output powers, monthly licensing fees, and severe overcrowding on the airwaves. Also, there is a language barrier because many 11-meter operators speak little or no English. It is a very disheartening situation, to say the least. Therefore, they have three options available. One, pack up the radio in its box and place it in the closet; two, stick it out on the band; or three, get an amateur license and talk to the world. I don't have to tell you that many choose option number three.

Secondly, many military members are met with the misfortune of having to serve at remote installations in places that you and I never thought existed. However, someone has to do it. In this case, amateur radio is a tremendous boost for one's morale.

And finally, there are those individuals who want the license only to talk with the family back home. I have run across several people whose parents were licensed but never did force the radio or electronics on them when they were growing up. Now they have the motivation and time they need to get that ticket. Besides saving on phone bills, writing letters, and waiting in line at the local MARS station, getting the license would please the heck out of Mom and Dad.

Although the reasons I have stated for military personnel and their families wanting an amateur license are generalizations, they are real. They are the sparks that ignite the fire . . . motivation is the key.

Once an individual has decided that he would like to pursue amateur radio as a hobby, his next step is to locate a licensed ham in the area for more information. Most larger military installations have active amateur radio clubs, but this is not always the case. Therefore, a check with the local MARS station is a good idea. If there isn't someone working there who is licensed, they will usually refer you to someone who is. What happens next? Well, if the military installa-

tion itself and the surrounding community is saturated with a large number of Americans, chances are that some sort of licensing program exists. For the smaller installations, it's a somewhat different situation. There may be only one or two active hams, but in the spirit of amateur radio, they will undoubtedly be helpful and outgoing. One interesting point I should bring up here is that the *Stars & Stripes* bookstores overseas are usually stocked with the ARRL license manuals, *Radio Amateur's Handbooks*, and the latest copies of *73 Magazine*. Therefore, individualized study, reinforced with the tutoring and supervision of an Elmer, will usually reap good results. Individual study of a subject which is diversified and foreign to most people, such as amateur radio, is a major undertaking that requires considerable motivation and determination when no other help is available.

The military life-style can be more demanding than its civilian counterpart, and because of this, not every ham has the time for the individualized tutoring of an aspiring student. It's a sad fact of life. However, there are some hams who care enough to make time and are doing a great job of getting the newcomers started. What follows is one of many such success stories that are taking place in West Germany where an overwhelming number of American military and civilian personnel and their families live and work.

A Ham Who Cares

Hahn Air Base is located about 50 miles west of Wiesbaden. I arrived there on orders from Uncle Sam back in March of 1979. Before I even processed into my squadron, I dropped by the MARS station in hopes of locating another ham. The military operator on duty there directed me to Steve Hutchins, who was acting as a contact point for the hams. Steve was one of those individuals like myself who first started out with CB radio. He was first licensed in 1977 as a Novice, WD6BKA. Shortly thereafter, Steve upgraded to General and received the reciprocal call, DA2HS. During that first meeting we had together, he gave me the full rundown. There were 10 hams stationed at the base, but no formal club to speak of. One of those hams, Floyd Bixler WD8DUP/DA1VF, was teaching an amateur code and theory class every Sunday for several of the personnel stationed here. Floyd had to cancel his classes due to other commitments, but only after everyone had successfully passed the Novice examinations.

At this point, Steve took over the reins and put the word out through various channels that an amateur radio code and theory class would be starting. Steve was well qualified to teach due to his excellent working knowledge of electronics, something he never learned in school, but on his own in his spare time. Assisting Steve in the classroom was Bob Haggart, who was very knowledgeable in the radio and TV repair field and at that time was a Novice with the call KA3CSE. Steve also enlisted my help to teach propagation and regulations and substitute for him when it was impossible for him to be at class. Steve carefully planned the learning sessions so that the conclusion of the three-month class would occur just when the FCC was due to arrive.

The FCC travels to West Germany twice a year in order for American military and civilians to test for their amateur and commercial radio licenses. Steve's plan was to get everyone a Novice ticket at the end of the first month; then he could teach them the additional theory needed to pass the Technician exam.

A Novice license is of little or no value in some countries under current reciprocal agreements, but since Germany recognizes the interim permit issued by the FCC as being a valid license, when a Novice ham with a callsign upgrades, he is immediately eligible to apply for a reciprocal German license without waiting 6 to 8 weeks for a callsign and license from the FCC. But the pressure is really on to pass the exams, because if an individual fails this attempt at the examination, it is six long months before there is another chance to test. This is one of those unique problems that the American citizen abroad encounters. Many students of amateur radio lose their interest and bail out because of this unfortunate situation. More on this later.

Steve's first class had its share of students who dropped out for various reasons. Those who hung in there and worked hard upgraded to Technician or General. This is the only reward that a teacher can receive, and the majority of his students rewarded Steve generously.

An interesting point to bring up here is that the student of amateur radio in Germany has it a little bit rougher than the student back home. The reason is that everyone's aim is to achieve at least the Technician-class license because it gives more operating freedom under the German reciprocal agreement. Therefore, not only does the student have to be familiar with the US regulations for the test, but also with the German regulations if a reciprocal license is desired. When it comes to frequency allocations and authorized emissions, things can get very confusing, even for the old-timer.

Steve has no magic formula for teaching or recruiting people into amateur radio. Patience and determination are the virtues that produce results. Steve is not a one-man show or Super Elmer. He regularly invites other hams in the area to help him teach classes. Their experience in the areas of ham radio in which they specialize is a great asset in helping the students learn and hold their interest.

Along with teaching code and theory, Steve has been putting much time and effort into the Air Force MARS program, which provides valuable training for new licensees. How he finds time to enjoy his rag-chewing, DXing, building, and troubleshooting is beyond me. Besides all of this, during 1980 he still managed to obtain his amateur Extra license (KN6G), his Second Class Radiotelephone license, and another stripe to wear on his sleeve. What more is there to say?

What Determines Success

You are probably asking yourselves, what's the big deal about four people getting their Novice tickets? Actually, I am trying to make a point. The dictionary defines success as "a degree or measure of succeeding; a favorable termination of a venture." For some strange reason, many amateur radio classes never materialize because someone determines that not enough people are interested. Baloney! The success of a class or study group is not dependent on its size but on the basis that something constructive has been accomplished. An amateur radio class does not have to be congested with so many bodies that a "Standing Room Only" sign is hanging

at the door. This is utter nonsense! Many are denied entry into our great hobby due to such primitive thinking. As I suggested before, individual study should be avoided where possible. Classroom study with supplemental home study is the way it should be done. If every radio club across America started some sort of training program, no matter how big or how small, we would be in a lot better shape.

All radio clubs across the country should get into gear as quickly as possible and drum up constructive and educational amateur radio classes. Look where it has taken the Japanese! It certainly hasn't hurt them. Here in West Germany, hams serving with the Air Force are doing their part. Classes are regularly held at Ramstein, Sembach, Hahn, Zweibrucken, Rhein Main, and in the Spangdahlem and Bitburg areas. I am not familiar with what the amateurs in the Army in West Germany are doing regarding amateur radio classes in their communities, but judging from their numbers, they must also be active with classes. Perhaps someone would like to write a follow-up and let us know what they are doing also.

FCC Policies: Hurting the Growth of Amateur Radio

As I mentioned earlier, the FCC travels twice a year to Germany, once in the spring and once in the fall. This certainly is not often enough! Now there is talk of no visits by FCC examiners due to the cost of travel, etc. They have got to be kidding! The US government gives millions of dollars away to countries who have stabbed us in the back and continue to do so, yet they can't seem to allot a few thousand dollars a year for examiners to test Americans abroad. The U.S. military and civilians who are serving overseas defending our great country deserve some consideration. Perhaps the FCC could institute some type of system similar to the Conditional licensing program that existed some years back. Or else they should consider traveling overseas more often. Amateur radio operators perform a public service with emergency communications and enhance international goodwill. If these policies remain in effect an extended period of time, the growth of amateur radio will resemble a centipede with sore feet . . . yes, that slow!

It would be much more comforting to know that the FCC was working with us and not against us. But, like other government agencies, the FCC is a strange animal with its own behavioral patterns. Until we find out what their last minute decision-making will bring forth, we are gritting our teeth and rolling with the punches.

This article was prepared in order to illustrate the present situation concerning Americans abroad. Amateur radio is sought as a hobby and/or morale booster by many because of those unique motivation factors. Secondly, licensing classes are reality, thanks to those who care enough to give of their time. And, to repeat what was written earlier, the success of a class or study group is not dependent on its size but on the basis that something constructive is to be accomplished. Think about it. And finally, current FCC policies are hurting the growth of amateur radio with no reversing trend in sight . . . that's the bottom line. ■

MBA READER™, A NAME YOU SHOULD KNOW

What does MBA mean? It stands for Morse-Baudot and ASCII. **What does the MBA Reader do?** The RO model (reader only) uses a 32 character alphanumeric vacuum fluorescent display and takes cw or tty audio from a receiver or tape recorder and visually presents it on the display.

The copy moves from right to left across the screen, much like the Times Square reader board. **Is the AEA model MBA Reader different from other readers?** It certainly is! It is the first to give the user 32 characters of copy (without a CRT), up to five words at one time. It can copy cw up to 99 wpm and Baudot at 60-67-75 and 100 wpm. Speeds in the ASCII mode are 110 and hand typed 300 baud. The expanded display allows easy copy even during high speed reception.

The AEA model MBA has an exclusive automatic speed tracking feature. If you are copying a signal at 3-5 wpm and tune to a new signal at 90 wpm, the MBA catches the increased speed without loss of copy.

The MBA Reader allows a visual display of your fist and improves your code proficiency. It is compact in size, and has an easily read vacuum fluorescent display.

The Reader operates from an external 12 VDC source. This allows for portable/mobile or fixed operation.

Check the AEA model MBA Reader at your favorite dealer and see all the features in this new equipment. If your dealer cannot supply you, contact

The Masher

—son of The Amazing Audio Elixir

When I first read the article on which this article is based, "The Amazing Audio Elixir," *73*, September, 1979, I really didn't read it at all. It looked a little hokey. Words like "amazing" and "cure-all" turn me off, especially when they're used to describe an audio limiter, processor, compressor, etc. I flipped on through the magazine to find something more interesting and useful. It wasn't until several months later, when a friend asked me to help him check out a compressor he had just built, that I gave any serious attention to N6WA's article and circuit.

My friend, John W8SSM, had built The Amazing Audio Elixir and he was anxious to receive some on-the-air reports. John was using the Elixir with his Kenwood T-599D and Heath SB-221. We were on 40 meters and the band was in good shape. I would be able to give him an accurate and, I expected, negative report. It had long been my belief that unless you wanted to spend a tidy sum for a store-bought rf speech processor like the Vomax, all that an external audio limiter, processor, compressor, etc., would do would be to junk-up an otherwise clean and intelligible signal. Got the picture?

John started the tests: "Compressor on: 1, 2, 3, 4, 5 . . . Compressor off: 1, 2, 3, 4, 5 . . ." And on and on. I couldn't believe what I was hearing! The blooming thing actually *improved* his signal! It reduced the peak-to-average ratio of his audio, and it seemed to give his audio more brilliance; that is, it attenuated many of the lows, which only consume power without adding to intelligibility, and it enhanced the mid-range and highs. It did this *without causing undue distortion and without raising background noises noticeably.* John turned on The Amazing Audio Elixir, and he turned me on to it. I liked what I heard, and I decided that I should have one.

It should be noted that the circuit diagram appearing in the original *73* article contained one error. It showed the gate of Q1 and capacitor C4 connected to the junction between R1 and R2. This should not be, and the corrected diagram is shown in Fig. 1. This is the circuit that John used and that worked so well as is.

But few things are so good that they can't be improved upon. After all, the original Elixir was described as a multi-purpose device—for tape recorders, computers, phone patches, repeaters, etc. N6WA mentioned only in passing that it might be used as a transmitter speech processor/compressor.

So, I set out to optimize the Elixir for use as a

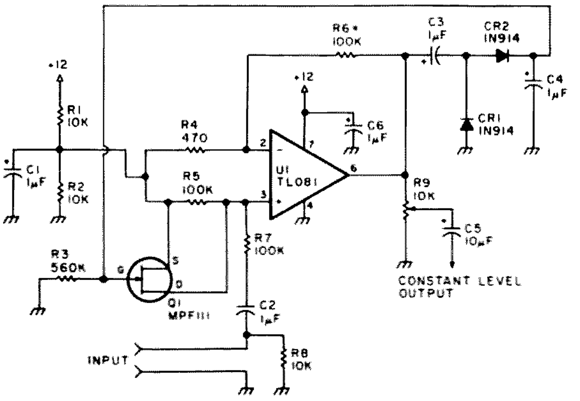

Fig. 1. Original circuit of the Amazing Audio Elixir (with correction).

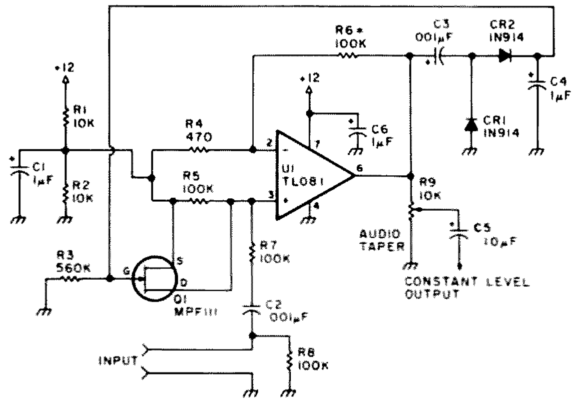

Fig. 2. The Masher circuit, fine-tuned for speech processing tasks.

transmitter speech processor/compressor. By the way, John found it clumsy to refer to the gadget by its given name, The Amazing Audio Elixir, or by its generic name, a transmitter processor/compressor, so he tagged it The Masher. It does "mash" the audio peaks down closer to the average modulation level—a descriptive name, I think, and a whole lot less clumsy to use.

Fortunately, N6WA makes available a neat 2" × 2" printed circuit board for $3.50 ppd. I ordered one, and when it came I was pleased to find that an accompanying data sheet gave significant technical information and specifications, which I found useful in my subsequent modifications. For example, the original circuit provides an af range of 100 Hz to 25 kHz to the 2-dB points. Ham transmitters don't need that extremely low frequency response. The data also showed that the input impedance was 10k Ohms. My microphones are high impedance. These considerations prompted the modifications to change the Elixir into the Masher. The modified circuit is shown in Fig. 2.

Experiments and on-the-air tests indicate that changing R8 from 10k to at least 47k not only raises the input impedance, but also allows a high-impedance microphone to retain its original characteristics. Values from 47k to as high as 1 meg were used without noticeable difference. I settled on 100k.

C2 and C3 were changed from their original values to 0.001 μF, providing a low-frequency roll-off at about 400 Hz. R3 was changed to 470k (Radio Shack does not stock 560k) with no effect on performance. And, finally, I used a regular 1/2-Watt audio-taper potentiometer for R9 and mounted it on the front panel of a small minibox. The multi-turn, board-mounted trimpot originally specified made adjustment of the output level much too difficult.

Construction is simplicity itself, whether you use N6WA's PCB (that makes it really simple) or perfboard. The hardest part for me was drilling the holes in the minibox for the switch, potentiometer, microphone, and power connectors—and that was easy. I should caution you, however, to be careful in your selection of cable to be used between the microphone and the Masher and between the Masher and your transmitter, especially if you use a high-impedance microphone. Use a shielded cable, but *do not* use the type that has the audio *and* PTT wires inside the shield. Only the audio wire should be inside the shield, as the PTT wire may carry hum and rf to the sensitive audio stages. I recommend Belden No. 8734 (straight) and Belden No. 8497 (coiled) for this purpose.

Testing and adjusting the Masher should present no great problem, especially if you have a cooperative friend with a good ear for audio. With the Masher switched out of the circuit, adjust your transmitter microphone gain as usual, for an alc indication of one-half to two-thirds of the alc range while close-talking the microphone at one to two inches. Set the Masher output level control at minimum, switch the Masher in, and while continuing to talk in a normal voice slowly increase the Masher output level until the alc meter *just begins to flicker*. In most cases, further adjustment will not be necessary. By no means should you try to kick up the alc meter as high with the Masher as you do without it. If you do, your friend out there, listening with the good ear, will probably tell you that your audio doesn't sound very good and that the background noise is too high.

A final word. I didn't have any particular problem finding suitable parts or substitutions for the MPF111 or the TL081—lucky, I guess. But you may save yourself a lot of time by ordering them from N6WA (C. W. Electronics, Box 8306, Van Nuys CA 91409). The PCB is $3.50, the MPF111 and TL081 are $2.00, and a complete kit of parts is $14.95.

That's all there is to it. Try it and you'll be amazed. ■

Innovation or Consternation?

—recent patents dealing with radio

Keith Greiner AK0Q
421 N. Pleasant Hill Blvd.
Des Moines IA 50317

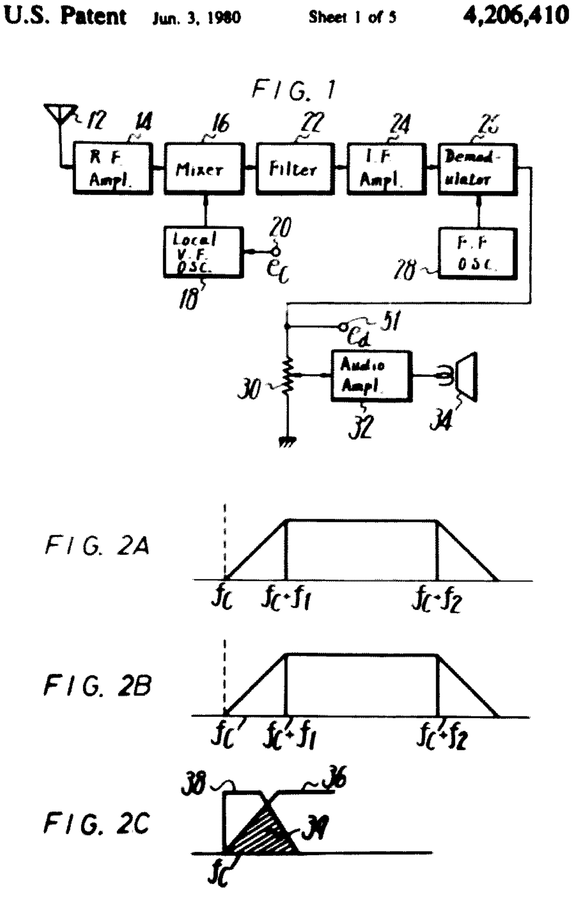

Fig. 1. Automatic frequency control system.

There is an old saying which says that in the life of every person there is one good book. So it is with inventions and amateur radio operators. There is at least one good patentable idea in every good ham operator. What about that little change you made to your antenna, or that FET you stuck in your FT-101?

It is entirely possible that if you wanted to spend the time and money you could discover that your idea is patentable as a new and unique device. As such, it could put your name on the list of over four million pa-

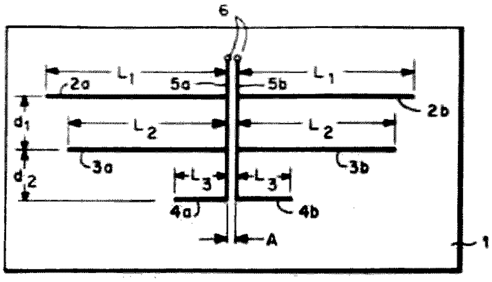
BROADBAND MINIATURE ANTENNA
ıul T. K. Young, Westwood, Mass., assignor to Louis Orenbuch, Weymouth, Mass.
Filed Dec. 21, 1978, Ser. No. 971,652
Int. Cl.[2] H01Q *21/12, 9/44*
S. Cl. 343—720 4 Claims



1. A broadband antenna comprising
(1) a pair of parallel closely spaced elongate central conductors, each of said central conductors being connected at one end to antenna output terminal means,
(2) a plurality of pairs of dipole elements, the two elements of each pair being equal in length, the elements of each pair being disposed symmetrically on opposite sides of said closely spaced central conductors and extending outwardly therefrom, each element having its inner end connected to the adjacent one of the pair of closely spaced

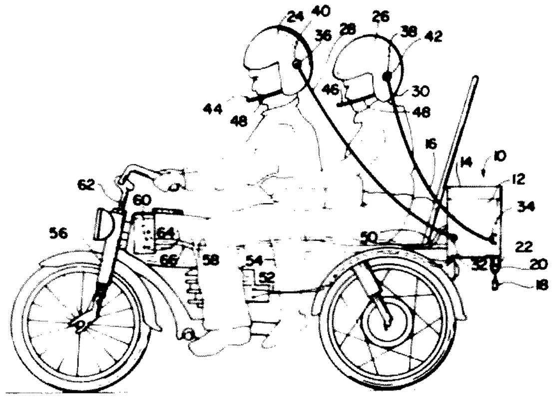

FIG. 1

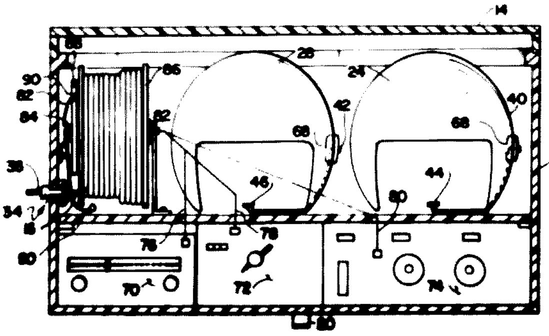

FIG. 2

Fig. 2. Helmet-to-helmet communications.

tents by creative people from all over the world. The list is a giant conglomeration of creativity with ideas from the truly unique to the absolutely absurd . . . from the extremely useful million-dollar money-makers to some which are obviously million-dollar boondoggles.

But for people who are constantly wondering "what makes it tick," finding out how others made it tick can be a fascinating pastime. A perfect source for details of these new ideas is the illustrated weekly publication of the US Patent Office, the *Patent Office Gazette*. The publication is usually about an inch thick and contains hundreds of interesting ideas patented during the previous week.

A subscription to the *Gazette* is not inexpensive; it runs about $300 per year. But for purists, I can imagine that curling up with a copy of the *Gazette* at night could be just as interesting as a Nancy Drew mystery is to a junior high school girl.

Unfortunately, the Patent Office doesn't publish information about inventors or their hobbies, so it is impossible to determine how many of them are amateur radio operators. However, it is easy to surmise that many of the ideas might be the direct result of a night of DX-chasing on twenty meters.

Patents are also a way to see the direction that our technology is taking. In fact, there is a section of the Patent Office called the Office of Technology Assessment and Forecast. Some of the basic changes are obvious. For example, it wasn't very long ago that parts used in patents included tubes, mechanical relays, and switches. Now they include many block diagrams showing the flow of logic and processing used in the invention.

Following are some summaries of inventions which have been patented recently.

4,206,410
Automatic Frequency Control System for Single-Sideband Signal Receiver

This invention (Fig. 1) was patented by two Japanese men, Hideo Ito Sagamihara and Haruo Hiki. It could be perfect for locking your receiver to the transmitter of your friend on the other end. With it, you would never need to touch the dial for perfect reception once you've established contact.

The invention works in quite a simple manner. The received single-sideband signal is passed through a low-frequency audio filter. The low-frequency signal has been modulated at the transmitter with a signal which your receiver uses to keep your receiver on exactly the same frequency as the transmitter.

How ingenious! Why didn't I think of that?

To imagine the most absurd possibilities, if your friend's transmitter were a bit unstable, the two of you could go floating along together all across the 80-meter band. On the other hand, given good engineering practice, this device

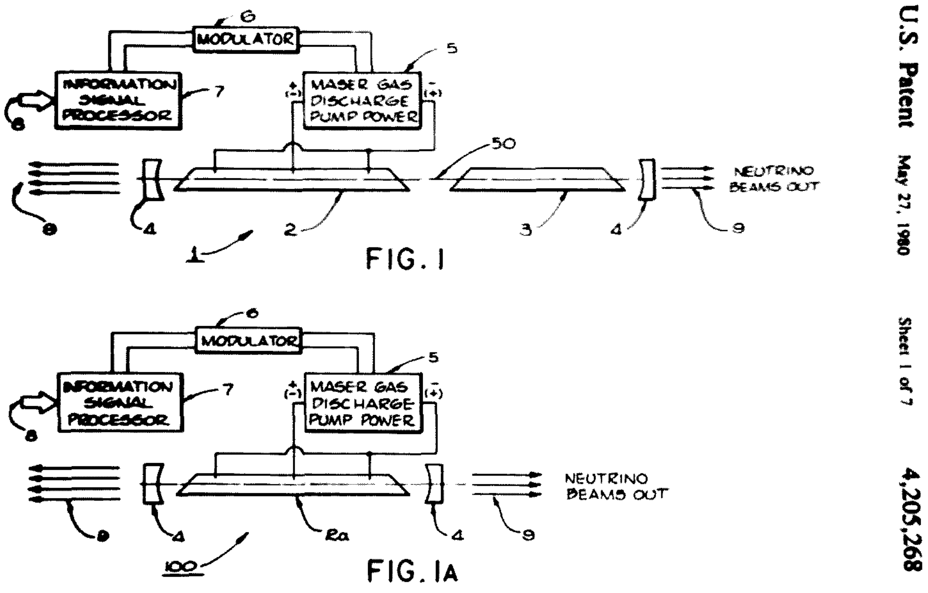

Fig. 3. Intelligence-modulated neutrinos.

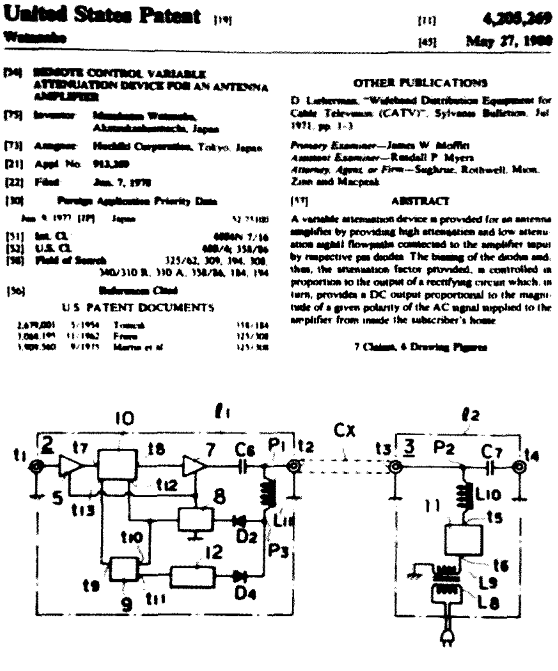

Fig. 4. A device for an antenna amplifier.

could appear in a future generation of improved transceivers and be heralded as a useful innovation for the industry.

Look for this invention to appear first in some piece of Sony equipment. The two inventors have assigned their patent to that company.

4,206,409
Motor Vehicle Communication Apparatus

This novel device by Samuel A. McKinney of Pickering, Canada, could be just the thing you need for mobiling from your Honda. See Fig. 2.

It is made up of two or more helmets, containing microphones and earphones. The helmets are connected to a receiver, an amplifier, and a control box. Now, when you're seeing the world on your cycle, you can listen to some nice music, talk on the repeaters, and even hold a decent conversation with your friend on the back.

I can imagine using the helmet and microphone combination in my car so that my wife and I can communicate while the children yell to their hearts' content in the back seat.

4,206,396
Charged Aerosol Generator With Uni-Electrode Source

Could this be the answer to portable power at your campsight? (See Photo A.) Would it help you chalk up extra points on Field Day? Alvin Marks of Whiteside, New York, may think so.

Marks says that you can change wind power into electric power by producing charged liquid droplets, putting the droplets into a windstream, and discharging them through a load and a grounded electrode.

No doubt, bright ideas like this may one day solve our energy problems. For this one, I surmise that you'll need to charge batteries or find a place with a steady wind. Now, with my ingenuity I'd probably just hook it up to a big fan.

4,205,268
Neutrino Communication Arrangement

Could we some day have ham radio communications on the Neutrino Bands? Neutrinos are neutrally charged particles found in atoms which have a mass of nearly nothing.

Josef W. Erkens, of Pacific Palisades, California, theorizes that by producing a stream of neutrinos, then modulating that stream with intelligence, you can transmit that intelligence to wherever the neutrinos go. Erkens also has patented the idea of a receiver for this system. (See Fig. 3.)

4,205,269
Remote-Control Variable-Attenuation Device for An Antenna Amplifier

This little device could be perfect for that preamp on your antenna (Fig. 4). In essence, the inventor, Masakatsu Watanabe, sends an ac signal from the control box to the preamp along the transmission line. Two diode circuits at the control box allow him to change the amplitude of one-half cycle of the ac. By comparing the difference in amplitude of the two ac half-cycles, the preamp circuit can determine how much to attenuate the output signal from the preamp. The current from one of the half-cycle signals is also used to power the preamp at the antenna.

I see this as an excellent innovation in the field, and one which may soon appear on many antenna circuits. The patent, number 4,205,269, has been assigned by the inventor to

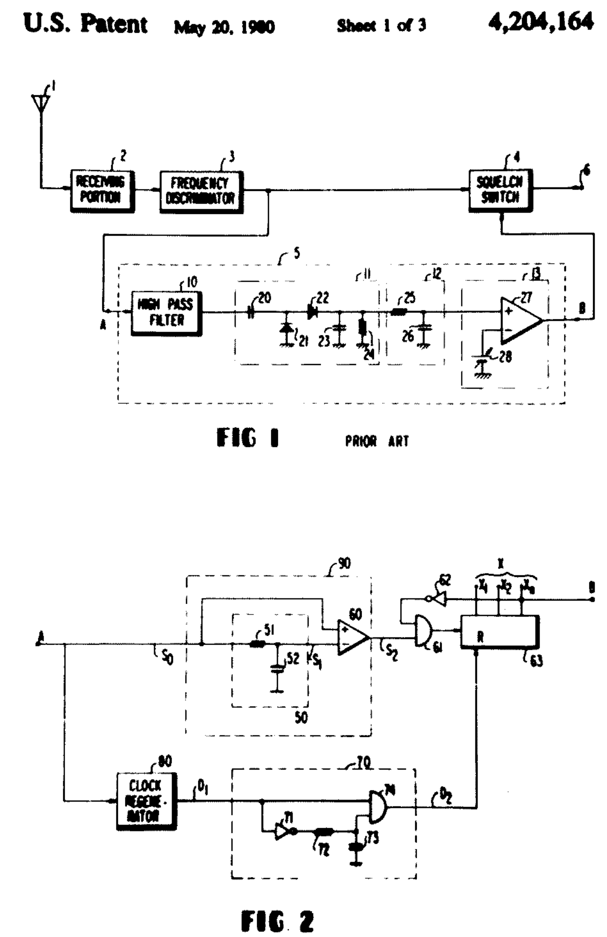

Fig. 5. Taking a noise pulse.

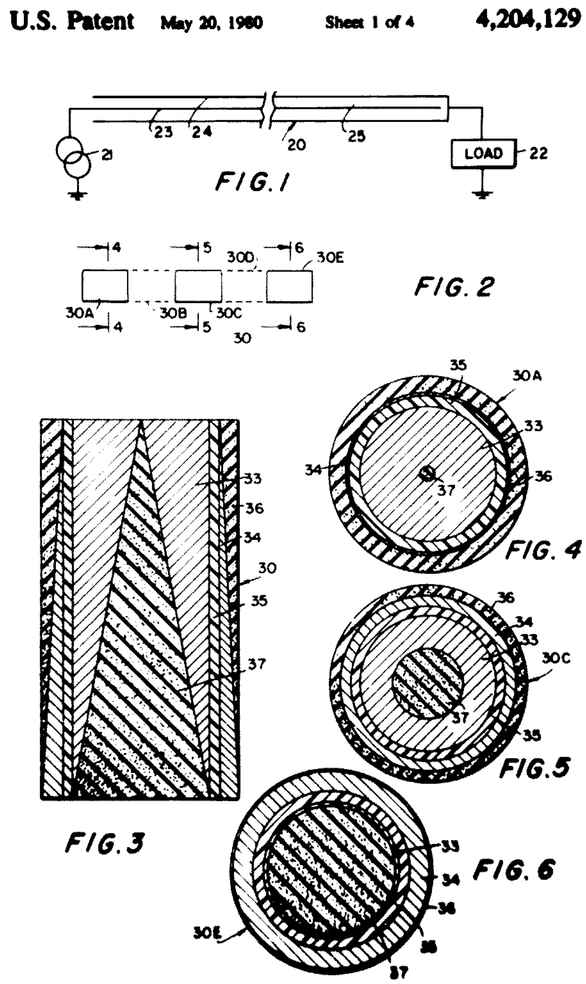

Fig. 6. Capacitance-compensated cable.

the Hochiki Corporation of Tokyo.

4,205,317
Broadband Miniature Antenna

This interesting antenna, shown in Photo B, is made of three dipoles which are spaced apart from each other by somewhere between a half- and a quarter-wavelength of the highest frequency to be used.

The longest dipole pair is approximately one eighth of the wavelength of the lowest frequency to be used, while the shortest dipole is roughly a third of a quarter wavelength of the highest frequency to be used. The middle length dipole is, according to the inventor, Paul Young, of Westwood, Massachusetts, "some intermediate frequency in the broadband."

4,204,164
Noise-Detector Circuit

Having trouble detecting noise lately? Here is a circuit by a Japanese inventor which is designed to do the trick for you—see Fig. 5.

The circuit, which has been assigned to the Nippon Electric Company, is described as consisting of a first circuit for slightly delaying a received signal which contains noise. The output of the first circuit is then fed into a second circuit which converts the delayed signal into a number of pulses. The rate of pulses per minute is directly dependent on the level of the noise being detected. By counting the number of pulses, you know the noise level.

Although it sounds simple enough, I am sure that the actual details, which may be found in the original patent documents, are anything but simple.

4,204,213
Flexible Dipole Antenna

I can just imagine this dipole antenna made of a bright yellow ribbon-like material, and wrapped around an old oak tree or perhaps a small house. It may be just the thing you'll need to toss into a trunk while preparing for your next trip. (See Photo C.)

Int. Cl.[3] H01Q 1/38

U.S. Cl. 343—700 MS 9 Clai

1. An electrically small microstrip antenna, which co prises:

a substantially cylindrical dielectric tube having inner a outer cylindrical surfaces;

Photo D. Conformal spiral antenna.

The *Gazette* describes this antenna as a flexible substrate (the ribbon) with a conductive material attached to it in a predetermined pattern. The pattern isn't described in detail, but we can assume it is most likely used for matching, length adjustment, and Q adjustments. To make things more complex, this layer is covered with another layer of flexible insulating material which has a conductive material attached to it. To top off the sandwich, another layer of flexible, insulating material is then attached, to make three layers of insulation separated by two layers of conductive material.

The patent has been assigned to the Westinghouse Electric Company.

4,204,212
Conformal Spiral Antenna

There is no mention in the *Gazette* description of this antenna of what type of equipment it is intended to be used with. So, at this point, we can assume it is as useful as some designer wishes to make it. The US Army, in its wisdom, must think this is a useful invention, for they have been assigned the patent rights by the three inventors.

The unique design is made of a cylindrical dielectric tube. (See Photo D.) On the inner surface of the tube there is a conducting material which is described by the inventors as "a conductive ground plane." A spiral strip of conductive material is placed on the outside of the cylinder. All you need to do is connect the two conductive surfaces to your feedline, and you have a "conformal spiral antenna."

4,204,129
Capacitance-Compensated Cable

Perhaps the best explanation of this design for cable is that it turns the cable into a series-capacitor between the frequency generator and the load. The generator is connected to the center conductor of the cable and the load circuit is connected to the shielding of the cable. The two circuits are completed through ground. (See Fig. 6.)

In order to compensate for and control the capacitance, the surface area of the center conductor is designed to become smaller as it approaches the load, while conversely the surface area of the shield is designed to become smaller as it approaches the generator (or vice versa). ■

Fred Hurteau WD4SKH
Rt. 5, Box 23-T
Whiteville NC 28472

The most agonizing ordeal you as a Novice must go through is not the code test, the written exam, or the waiting to hear whether you've passed the test or not. The worst thing you have to go through, by far, is choosing your first rig.

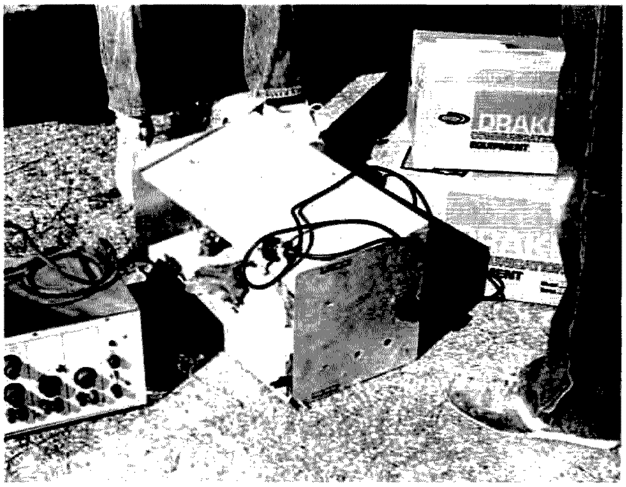
How do I know how much money I'll need? (You ask yourself.) Where is the money going to come from? How do I know what is a good price? What kind of rig do I need? What features do I need? I can't afford a new $1200 Superbolt III. But how do I tell if a used rig is any good? I don't even know one kind of rig from another. Where am I going to find one? *Where do I start?*

All these questions and more go through your mind when it's time to get a rig. If you're lucky enough to have a ham friend who has the time to help you choose and to go to hamfests to help you look over the rigs, you'll not be totally lost. But your friend can only advise you, not choose for you. You can't hold your friend responsible when it turns out your purchase doesn't do what you wanted it to do. He didn't know what you wanted any more than you did! You must face the ultimate responsibility of making *your* choice and spending *your* money.

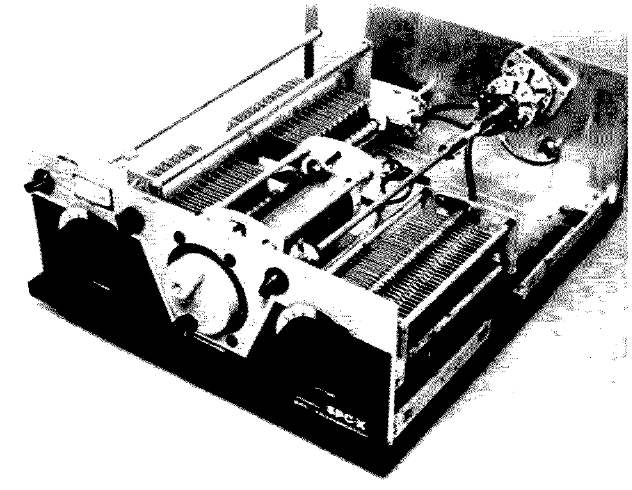
Whether or not you have a friend to help you, I think you will find this article helpful in deciding what you need, what you can afford, and how to go about getting it. It will guide you in organizing your thoughts and doing some conscientious planning *before* you take that important first step!

Where Will I Get the Money?

Empty your pockets and your piggy bank and count it. Uh huh, just as you thought, only $15.42 there. Well, where can you get more? How about selling something? Maybe you've outgrown your high school fixation about being in a



Would you give $3 for this junked home-brewed amplifier? I did. Along with plug-in coils, switches, insulated standoffs, and other goodies was the 12-inch long dual-section air-variable capacitor used in my home-built SPC transmatch. A real parts bonanza for just $3.



My home-built SPC transmatch uses the dual-section air-variable capacitor mentioned under the photo of the "junk." The single-section air-variable, the roller inductor with turns counter, and both vernier drives were salvaged from a junked military surplus transmitter purchased for $12 at a hamfest. The transmatch cabinet was designed to blend with my Drake equipment.

rock 'n' roll band. You never could play the electric guitar anyway, and it's collecting dust under the bed. Well, take it to the next hamfest and sell it for $50, or $100, or whatever you can get for it. How about that old dilapidated shortwave set your next-door neighbor gave you when you first got interested in radio? Maybe you can get $10 for it. If you have any hobbies like painting, woodworking, or arts and crafts stuff, you could try selling some of it. If you've ever been to a hamfest, you'll know that a ham is liable to buy anything. Hams have other hobbies and interests, too. Old model trains, guns, cameras, and many other items can get you a dollar or two if you're willing to part with them. So think hard! You can think of something to sell.

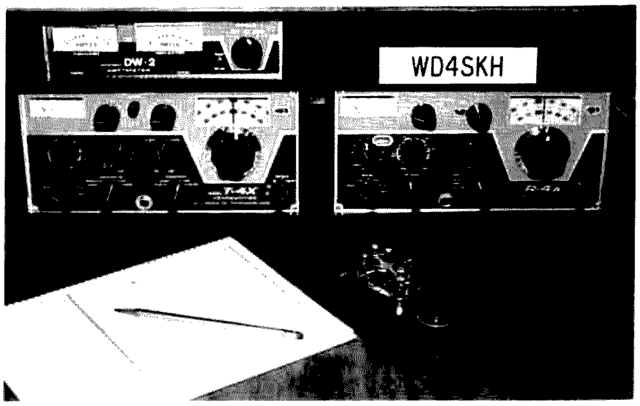
Am I Safe Buying Used Equipment?

Now that you've figured out where the money is coming from and how much you have to spend, you can begin deciding what you want to spend it for. You can purchase a used rig for around half its original price and get years of good service from it. If you buy good, clean used gear at a good or "steal" price, you can always sell it in a year or two for as much as you paid for it. In other words, as long as you take good care of it, your investment will not depreciate and you can get your money back to spend on a nicer rig when your finances allow such a move. That is the reason why good used equipment can be your best bargain.

El primo rule when buying used equipment is *buyer beware!* You can get taken by a shrewd seller more often than you can find a steal unless you exercise reasonable caution when buying. This is especially true when buying used transmitters, receivers, and transceivers. There can be aggravating minor problems that don't show up until you've had the rig on the air for a while. Usually the seller will admit to any obvious major problem with the rig being sold. Some will tell you every little detail, and some will swear it's in perfect shape when it's really a piece of junk. You and only you can be the final judge. If you can't tell by the look of the rig, then try to judge the look on his face.

Of course, no one selling used equipment can give you an ironclad one-year warranty on what he is selling. But if it hasn't given any major problems or had a recurring problem while he used it, you can assume you should have no major problems. If you can buy a rig from another ham you know and trust, you can probably get a better rig at a better price. In any event, when seriously considering buying *any* rig, ask to operate it, or test it out in some fashion before buying. This is an excellent way to see if you like the controls and features on the rig, as well as checking it for any defects.

In spite of a real need for such testing, it isn't always possible at a hamfest. In fact, it has been my experience that this is almost never possible at a hamfest. Hamfest organizers often claim they will have a testing area set up, but usually there is not even an electrical outlet set aside for such purposes. The minimum requirements would include a table, a dummy load for keying up, and some sort of wire hanging up for minimum reception. So if you want to buy at a hamfest and check out the rig first, at least ask, but don't be surprised if all you get is a run-around from the organizing club.



A matching transmitter-receiver combination is known as "twins." Shown here are my Drake twins, vintage 1967. In 1967, this set, with matching speaker and ac power supply, had a combined suggested retail price of over $950, including tax. They were purchased at a hamfest in 1978, complete and in excellent condition, for slightly over half the original price. The wattmeter atop the transmitter was home-built. Its cabinet was designed to blend with the Drake equipment.

What Is Better for Me, A Transceiver or Separates?

Now comes the question of whether to buy a transceiver or a separate transmitter and receiver combination. (By the way, a matching transmitter/receiver combination is known as twins. They usually look very much alike and are made so that they operate together without complicated external switching hookups.) Here are some points to consider when deciding on a transceiver or separates:

1) Transceivers are generally less expensive than a comparable set of matched twins.

2) Transceivers are generally easier to operate, due to the absence of controls duplicated in a set of twins (2 vfos, 2 band-selector switches, 2 tuning or peaking controls, etc.).

3) Transceivers can be more costly to have repaired due to the complexity of the combined transmit/receive functions crammed into one case.

4) Transceivers usually take up less space than comparable twins.

5) Twins are more versatile. Having a vfo on each unit gives you split-frequency operation without the purchase of an outboard vfo necessary for split-frequency operation with a transceiver. If one unit breaks down (the transmitter, for example), you still have the other unit to use (you can still receive and keep up your code practice) until repairs can be made.

6) Twins often have more good features as standard equipment than do transceivers.

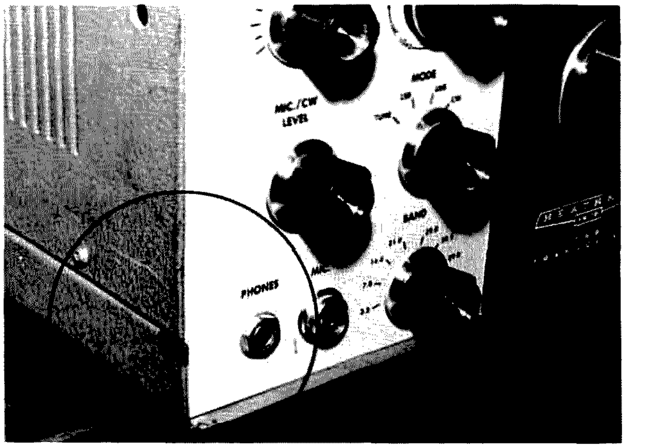
7) Separate transmitter and receiver units that are *not* matched (odd couples) can be hooked up, and in many cases may be less expensive than either twins or a transceiver.

Most Novices have no need for split-frequency operation available with twins or transceivers with an outboard vfo. Let your pocketbook be your guide on that point. Split frequency has its applications when working some DX, can be a help in contests and service nets, or it can be *confusing* if you don't pay attention to what you're doing.

How Much Is a Rig Going to Cost?

Now you should have

This is a popular model of transceiver, the Heathkit HW-101, purchased by one of my Novice students at a recent hamfest. A little bargaining got this gem, including ac power supply and CW filter, for only $175.



Don't let minor damage like chipped paint and superficial scratches (circled area) deter you from a good buy on an otherwise clean, operable rig.

three things taken care of: (1) where the money is going to come from; (2) how much money you have to spend, and (3) whether you are looking for a transceiver or separates. Now you have to decide which brands or models are within your financial means. This can be a specific unit to decide on, or it can be a list of several good possibilities in the range of your budget.

I strongly suggest checking the ham magazines for advertisements by dealers who list their used equipment and prices. These listings will give you a good idea of the market value of used units with the dealer's markup tacked on. Most dealers charge more than you'd have to pay for the same unit at a hamfest, but usually they have gone over the rig and checked it out before putting it on sale.

Many dealers will give some sort of warranty on used gear, too. If you like the idea of having the extra peace of mind that this might offer and you can afford the extra bucks, you might consider calling them. In any case, the information on current prices of used gear is an excellent help in judging the real value of a rig.

Compare the dealer's used prices with the prices in the classified ads of ham magazines. That also will help you develop some idea of fair prices for the rigs you are considering. (A word of caution is appropriate here if you are considering buying a rig from the classified ads. You're not only buying a rig from someone halfway across the country, but you're buying it sight unseen. At least at a hamfest you have the chance to look over the rig before you buy it. Prices in these classified ads can be a bit inflated, too. The seller must recoup his cost of advertising, and those ham ads do cost money.)

Another big help for me was a set of manuals called *Ham Equipment Buyer's Guide*, published by A.L. Brand WA9MBJ. They may be ordered from Barbara Brand Wixon, 189 Kenilworth, Glen Ellyn IL 60137. These manuals show pictures of commercial ham gear and military and government-surplus gear of interest to the amateur market. With each picture there is a description of the unit. Most have the date of manufacture or the date the unit came on the market, and its original retail price. These manuals cover gear from about 1945 to the present.

This was especially helpful to me in keeping all the Heathkit® rigs organized in my mind. There seemed to be so many that looked alike, I could never keep straight whether I was looking at a 6-meter rig or an HF rig. It was equally difficult for me to separate the transmitters from the receivers from the transceivers! It is a small investment when you consider that you may be preparing to spend $200 to $500 or even more on some equipment. Armed with this information, you now have something to choose from, and some idea of the cost.

Which Rig to Buy—When I Don't Know What to Look For?

Now comes the hard part. Different rigs have different features. What is standard on one rig may be an add-on option for another rig. The more goodies, such as RIT, audio filters, LED readouts, and speech processors, that the rig comes with, the more it is going to cost. If you've not operated any ham gear before, you may well have *no idea* what features you want in a rig or which features are worth the extra cost. So how do you know where to start choosing?

The following is a list of features you should consider and some explanations of what the feature is or does. Following each item are one or more letters. The T means that the feature is usually found on a transmitter, the R that it is found on a receiver, and the X stands for transceivers. Read over the list and ask each question appropriate to each rig you consider buying.

1) How many bands or portions of bands does the rig cover? Does it include a WWV receive function? If not, see item 5. (T,R,X)

2) Is it vfo controlled or single fixed-frequency crystal controlled? (T,R,X)

3) What is its rated input or output wattage? (T,X)

4) What modes does it have (AM, SSB, CW, RTTY, FM, etc.)? (T,R,X)

5) Is its band coverage easily expandable? Some rigs have accessory crystal sockets which give you extra band coverage in 400- to 600-kHz sections with the simple addition of one plug-in crystal. This is an important feature if you want to be ready for the new amateur bands recently allocated for our future use. (T,R,X)

6) For CW operation, does the rig have full break-in or semi-break-in? This

means you can hear your receiver audio between every dit and dah with full break-in, or only during longer pauses between words or sentences with semi-break-in. (T,R,X)

7) For phone operation, does the rig have PTT (Push To Talk), or VOX (Voice Operated Xmit—short for transmit), or both? (T,X)

8) Does the unit come with an outboard vfo, or at least have an accessory jack for an outboard vfo? (X)

9) Is the frequency readout digital (LEDs) or analog (dial markings)? (T,R,X)

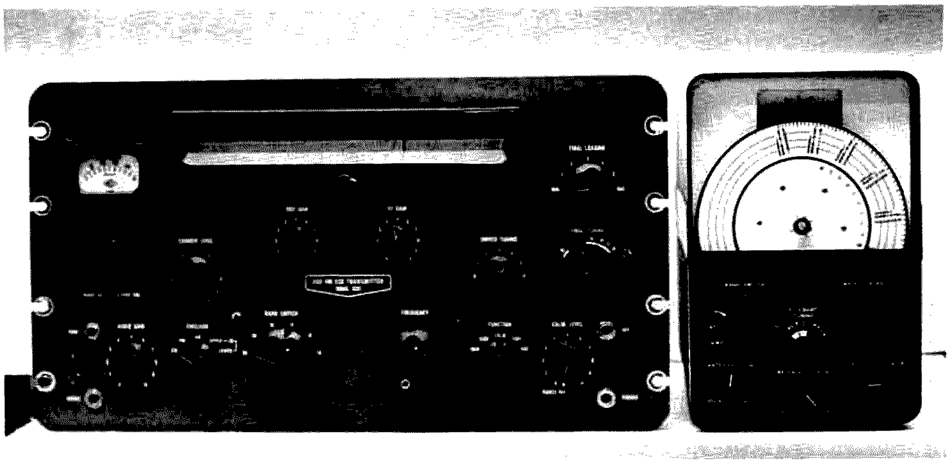
10) What is the bandwidth of the audio filters it comes with? For AM phone you need about 4.5-kHz to 5-kHz bandwidth, SSB phone requires about 1.5 kHz to 2.5 kHz, and CW, anywhere from 50 Hz to 500 Hz. There are two types of audio filters: active and passive. The active type amplifies the chosen audio-frequency band louder than the background, making it easier to hear over other audio. The passive type cuts down the background sounds and passes the chosen audio band. Active filters are less expensive but tend to sound harsher than passive filters. (R,X)

11) If it doesn't have the filter bandwidth you want as standard equipment, can it be purchased and plugged in inside the rig or must it be added externally? What would be the cost of the manufacturer's recommended plug-in type? (For example, new plug-in crystal filters can cost $40 and more!) (R,X)

12) Does it have a notch filter? This is sort of the opposite of an audio filter. A notch filter cuts out a particular thin band of audio. It is particularly helpful for filtering out a carrier signal in your audio. (R,X)

13) Does it have a noise blanker? (R,X)

14) Does it have RIT (Receiver Incremental Tuning—sometimes called a clarifier)? This feature allows you to shift your receive frequency 1 or 2 kHz without moving your transmitting frequency. This is a real help on a transceiver without an outboard vfo. (X)



At the left is a Gonset GSB-100 transmitter, vintage 1958, which sold for over $450 new. At the right is a Drake 1-A receiver, vintage 1959, which went for $300 new. These could be used as an "odd couple" to set up a Novice station. The Gonset is a rack-mount unit and should have some kind of cabinet on it for rf shielding and shock protection. It measures 10" × 18" × 20" and weighs 120 pounds! Be sure your operating table can handle it! (The decorative face plate is missing from the 1-A dial in this photo.)

15) Does it have a crystal calibrator (usually 25-kHz or 100-kHz increments)? A crystal calibrator is a built-in crystal oscillator which allows you to calibrate your vfo dial without having to use external test equipment. (T,R,X)

16) Does the rig come with its power supply built in, included as an accessory, or not included at all? (T,X)

17) Is the speaker built in, in a matching cabinet, or not included at all? (R,X)

18) Have there been any user-installed modifications? If so, what are they, and are they indicated on your schematic? (T,R,X)

19) Are the original operator manuals and schematics included? (T,R,X)

20) What is the appearance of the rig? Is it scratched, dented, rusty, cracked, knobs missing or mismatched, poorly repainted, etc.? (T,R,X)

21) Is the physical size and weight of the rig suitable for your available operating space and situation? (T,R,X)

22) What is the reputation within the ham community for the particular rig or rigs you are considering? (Examples: a reputation for frequency drift, poor audio quality, hard-to-find tubes, poor selectivity, hard-to-reach controls and adjustments, etc.) (T,R,X)

Boy, that sure sounds like a lot to think about, doesn't it? Well, it *is* a lot to think about. That's exactly the reason you should think about all these things *ahead of time*. You will find that before long you will automatically check for many of these items from memory, without having to refer to this list for them. Don't be afraid to take this article along as reference, though; you can't commit every one of these questions to memory. Mark those options you are considering. Star the ones you *must* have and mark the ones you would like but would pass over unless the price was right.

What Features Do I Really Need?

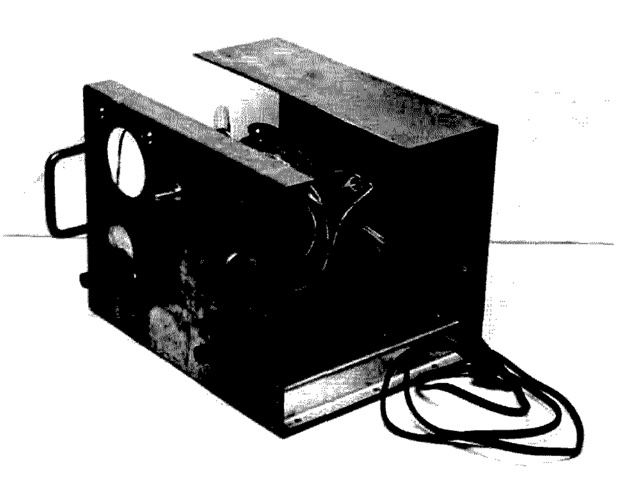
If you are still undecided about some of the features and options, the following list of comments and my own recommendations for Novices might help you decide. The numbering on this list corresponds to that of the previous list.

1) If you can afford an all-band rig, good! You will be happier with it in the long run. I recommend some type of WWV coverage. (Refer to item 5.)

2) Crystal control is pretty much a thing of the past. By the time you collect enough crystals to make a crystal rig of any value, you could have purchased a good vfo for the same money. If you can at all afford it, go for vfo control.

3) Wattage choice is a matter of preference (though the cost can be a minor factor). Many all-transistor rigs are 20-Watt input or less. Tube-type rigs generally run from 40- to 300-Watt input. The 50-to-100-Watt range is a good starting point for Novices.

4) As a Novice, you certainly need CW. SSB is a good option so that you won't *have* to buy again when you upgrade your license. AM, FM, and RTTY are of no particular value to



A home-brewed power supply like this one often can be purchased at a hamfest for less than the individual parts could cost used! Even if it doesn't work, you could use the good parts and cabinet and build your own. Refer to amateur publications like this magazine for construction projects on power supplies and many other useful items that are relatively easy to build.

you as a Novice.

5) If you can afford a rig with easily-expandable band coverage, get it. It will pay for itself in a couple of years when you upgrade, or when the new bands become available to amateurs. It is also an easy way to add WWV reception if the rig doesn't already have it. However, expandable band coverage is not a must for the Novice.

6) Full break-in or semi-break-in: The choice is a matter of personal preference. Full break-in normally is available only on the newer transistorized, digitalized rigs. Personally, I find full break-in annoying, but you should listen to a sample of it to decide for yourself. Semi-break-in is quite sufficient for the Novice.

7) VOX is nice when you upgrade, but is not a necessity for the Novice.

8) An outboard vfo on a transceiver is nice, but not a necessity for Novice use. RIT will serve you as well. However, if RIT isn't available on your rig you might consider an outboard vfo as a second choice if the price is right.

9) Digital readouts are pretty but definitely not a necessity for Novice use. Digital readouts cost more and give more trouble than an analog display. If you want pretty lights, get a good frequency counter. It will be of much more use to you now and later on.

10,11) The QRM on 40 and 80 meters can get awfully hairy in the Novice bands. A good audio filter can be a QSO saver and a nerve saver, too. The tighter the filter, the better. 500 Hz or tighter is good (almost a necessity) since you probably need all the help you can get copying CW on the air. Don't worry if the rig you pick out doesn't have a tight CW filter, though. You can build a good add-on active or passive filter from any of several projects covered in the ham magazines and other publications.

12) A notch filter is not a necessity, though it can be especially helpful on 40 meters where there are a lot of shortwave carriers.

13) If your choice of rig has a noise blanker, fine. But the cost of an add-on noise blanker could prove prohibitive to your budget. You don't really have to have one.

14) I recommend RIT if you get a transceiver. There are articles showing how to add RIT to many rigs. If the one you want doesn't happen to have RIT, check the annual indexes of the ham magazines (December issues) and other publications to see if there is an RIT modification for the rig you're considering.

15) If your choice of rig has a crystal calibrator, so much the better. You should have one. But if it doesn't, you can probably add one. Refer to the many amateur publications for details.

16) You *must* have the proper power supply for your rig. When buying a used rig, deduct from the going price if the power supply isn't included. You have to get one from somewhere, and they tend to cost more and are harder to come by when purchased individually. This is especially true of supplies for tube-type rigs. A 12-to-13-volt dc supply isn't as critical or as hard to find, though must still meet manufacturer's specifications for the supply for your rig.

17) You can buy a good speaker for a dollar and put it in some kind of enclosure if you have to. But deduct from the asking price if the receiver you want doesn't have a built-in speaker or a matching speaker cabinet.

18) User-installed modifications can be nice, but if they are poorly or improperly installed they may do more harm than good. Check workmanship carefully and see that it is marked in the schematic or manual with the unit.

19) You need the manuals and schematics. If they don't come with the rig, knock $3 to $5 off the price. You're going to have to order them and pay for them elsewhere.

20) If the rig looks bad, it's probably been taken poor care of. Beware. Also, you should learn to recognize the difference between fair wear on older equipment and downright mistreatment and abuse. Don't knock too much off the price for fair wear, but watch out for excessive wear or abuse.

21) Certainly don't get a rig that's too big and heavy for your flimsy operating table! However, if you have the room, some of those old, large rigs have a lot of good spark left in them, and they're cheaper, too!

22) Put your ear to the ground and listen. Reputations may or may not be fair. Often there is a simple modification that can cure the reputed problem with a certain rig. Ask around and see what you can find out. Write the manufacturer. He may be able to tell you what needs to be done to correct the problem.

What About Home-Brewed Equipment?

By now you should be well along in deciding what you want in a rig. However, there are still more things to consider before buying. Besides commercially-manufactured gear, you may come across home-brewed equipment for sale at hamfests. You should be especially cautious of home-brewed transmitters and receivers. You have no way of knowing the spectral purity of the transmitters or the sensitivity of the receivers. Often they don't even have a schematic so that you could troubleshoot any problems. Workmanship may be shoddy, though you can find beautifully-built home-brews on occasion.

It's a different story with home-brewed equipment such as antenna tuners, power supplies, and other simple-to-build items. Many times you can find a home-brewed antenna tuner for

sale for less than the individual parts and cabinet are worth. You may find a home-brewed power supply for less than the transformer and capacitors in it are worth! These can be excellent buys, even if only for parts. But other items such as frequency counters, electronic keyers, and other complicated equipment can be a real headache if home-brewed.

(While on the topic of electronic keyers, I wholeheartedly discourage Novices from using electronic keyers. A good military surplus straight key can be purchased for as little as $3. That's hard to beat on a tight budget. Electronic keyers are difficult to operate properly and sound absolutely horrid when poorly operated. The money spent on one can be much better spent on a dummy load, coaxial switches, antenna and tuner parts, etc.)

Another item found at hamfests is ye olde 23-channel (or 40-channel) CB mobile rig. For $10 to $60 you can get an AM or SSB CB for conversion to 10 meters. That's a cheap way to get on the air if you don't mind being limited to a single band. If you're not afraid to try a CB-to-10-meter conversion, then you might even consider trying to home-brew your own CW transmitter. Especially if you are willing to try QRP work, your chances of home-brewing a good CW transmitter are good. If you can get help from another ham who is an experienced builder, you will find that help very valuable with such a project. And a home-brewed direct-conversion receiver isn't so bad either. So keep these options in mind if your budget is limited.

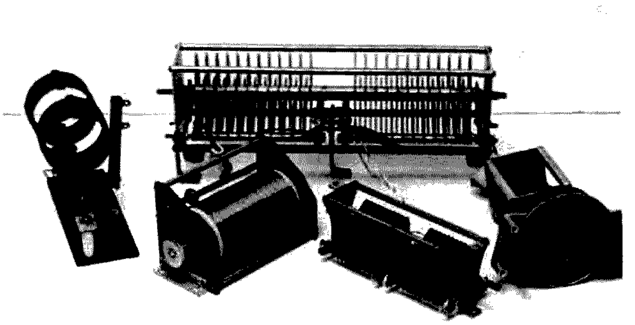
Anything you can home-brew for your station helps take the strain off your finances, and it gets you off on the right foot. Part of what being a ham is all about is being as self-sufficient as possible and not being afraid to try things yourself. Most everyone can build an antenna tuner, an swr meter or wattmeter, and other small items which can run into a lot of money if purchased commercially. I encourage Novices to home-brew as much of their station as their time, tools, workspace, courage, and talent will allow. If you've never tried it, you're missing part of the total experience.

I Think I'm Ready to Buy Now...

Don't forget that you have an option not to buy but to *swap*. You may be able to work out a good deal by swapping your old guitar for something you want. Or you could swap it for something you don't especially want which is worth more than your guitar and probably easier to sell. Then you could either swap that for something you *do* want, or you could sell it and use the money to get what you want.

When swapping or buying, a good rule to follow is: *Don't pay the asking price.* Even if the asking price is a fair price (according to your careful research and pre-planning), offer less! If your offer is accepted, fine. If not, you can probably agree on a price that's acceptable to both of you. But if you don't offer less, you'll never know if you could have gotten it for less.

Two dollars saved here and three dollars saved there will buy that five dollar item later. If you can't agree on a price that's acceptable to you, walk away. You may get called back, on your terms, before you've taken two steps! In any event, decide what your top dollar will be and don't pay more than that for it, even if it hurts. There are other fish in the sea. If you look on the next row of tables, you may find just what you want for less than you expected to pay.



When searching for goodies such as coils, roller inductors, and capacitors for your antenna tuner and other projects, don't pass up goodies like these because they are hidden inside something else. You very often will find the best bargains by rummaging around in and under what looks like junk! Be curious when shopping at a hamfest! The large capacitor in this photo is over 14 inches long!

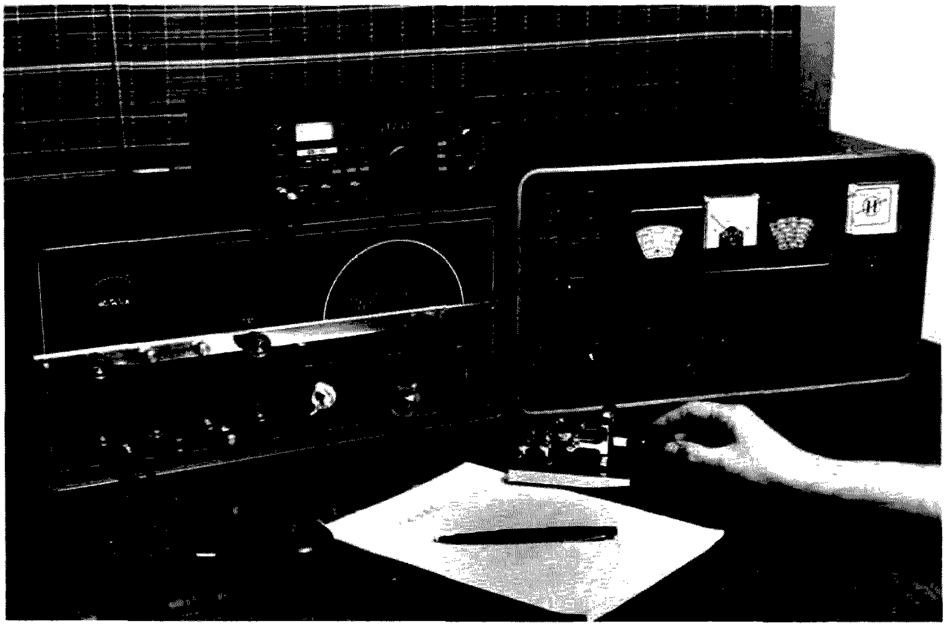
Of course, there are exceptions to this rule. Once you've gained some experience, you can spot a real steal when you see it. In such cases, it's often better to pay the price. If you wait until later, the guy behind you will have already paid the price and gotten the bargain. So if you're *sure* it's a steal, buy it whether you need it or not. You can put it on your table and sell it for nearer the usual asking price and make a little money on it, giving you just that much more cash on hand to get what you really need. With a little experience, you can become a real horse trader and still turn an honest dollar. A real steal at $3 can be bought and resold at an honest fair market price of $10, and you'll undersell the crook at the other table trying to get $20 for the same thing!

Ready to Go... Did I Forget Anything?

If you can remember the guidelines I've covered here, you will feel much more confident about your ability to judge used gear and its real worth. You'll not only be able to spot a good buy, like an old-timer, you'll be able to spot the rip-offs and junk, too. You'll know the right things to look for and to ask about before laying out your hard-earned money.

Plan ahead and know what you want and how much you'll pay for it. And when you find what you're looking for, stick to your top dollar and don't pay a penny more! Never go off half-cocked. If you have planned and prepared well, the time you've put in before the hamfest will save you money and anguish when trying to decide what to do. Don't buy the first thing you see unless you *know* it is a real bargain. Take your reference along for double-checking when your memory becomes foggy.

Check out the condition of transmitters and such carefully. Outward appearance is a hint, but testing is the *only* way to spot problems. If possible, have an experienced friend help you. Just having someone assisting in spotting what you're after can be more help than you realize. If your friend knows about used equipment, he can help advise you on its con-



The old and the new together: an Icom IC-730 transceiver sits atop an "odd couple." Left is a Hallicrafters HT-37 transmitter, vintage 1960, which listed for $450 new. At the right is a Hammarlund HQ-145-X receiver, vintage 1961, which listed for $285 new. Combined, they weigh 122 pounds! By comparison, the IC-730 will do everything the older pair will do, and comes in a package less than 4 × 10 × 11 inches! The 1981 vintage Icom lists for $829. The older pair can be purchased now for about half their original price.

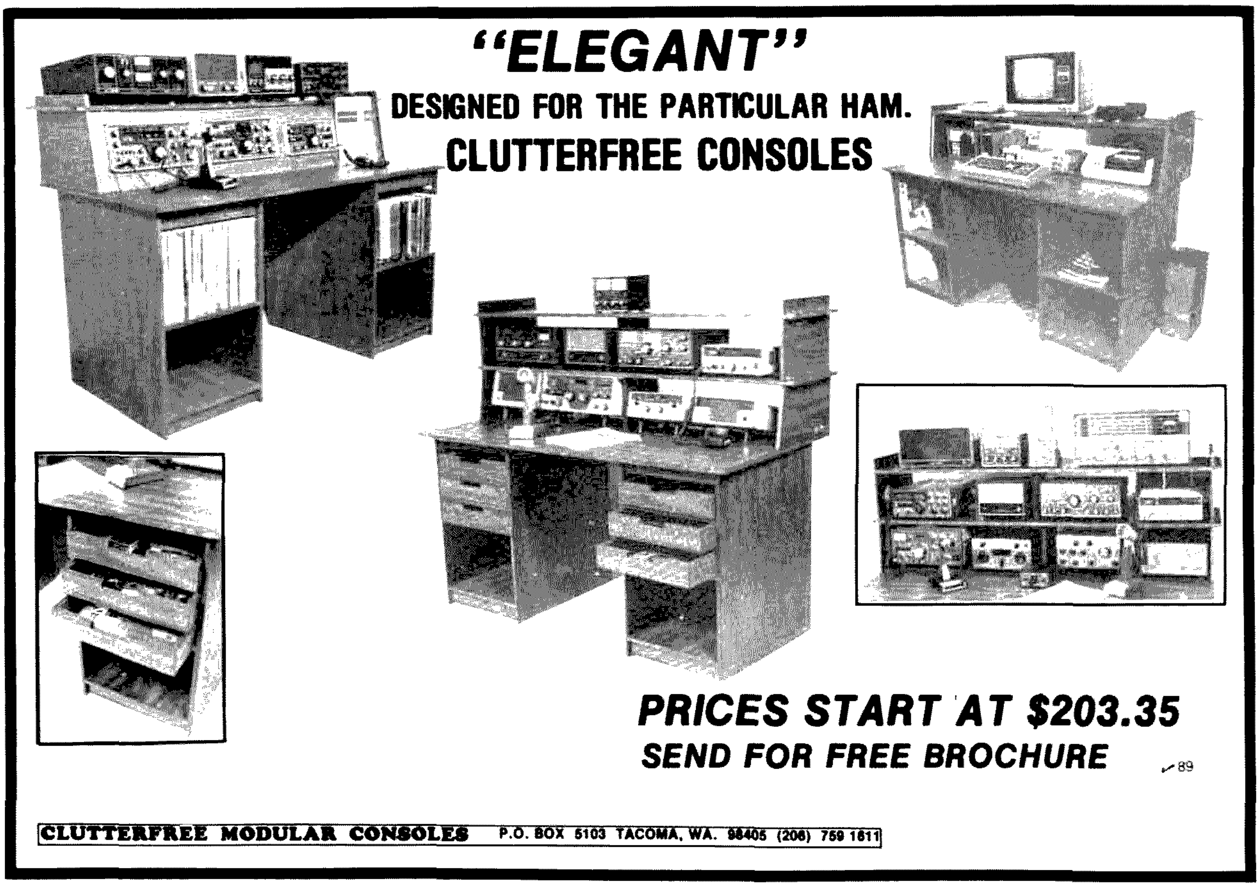
dition. He may be more experienced at spotting little things that you may overlook.

Even without the help of a friend, if you have prepared well you won't be totally at the mercy of the other guy's honesty or dishonesty. If you talk and look as if you know what you're doing, there's less chance the seller will try to take you for a ride at your expense. The only thing better than the *knowledge* you should now have is real *experience*. But that, too, will come in time.

I haven't forgotten my first attempt at purchasing a receiver and transmitter. If you follow these guidelines and suggestions, you can avoid the mistakes I made. I learned the hard way, but you don't have to. So go get 'em, tiger. And good luck! ■

Acknowledgement

My thanks to N4BGU and KA4YBJ for their assistance in assembling equipment for photos. Also a special thank you to KZ4J for his photo of "The old and the new together."



SOCIAL EVENTS

from page 61

22nd annual ARRL-approved Lafayette Amateur Radio Hamfest on Saturday and Sunday, March 13-14, 1982, at the Evangeline Downs Racetrack Club House facility, located directly off Highway 167, five miles north of Lafayette LA.

WINCHESTER IN
MAR 14

The Randolph Amateur Radio Association will hold its 3rd annual hamfest on Sunday, March 14, 1982, from 8:00 am to 5:00 pm at the National Guard Armory, Winchester IN. Tickets are $2.00 in advance and $3.00 at the door. Table space is $2.50 and table space with table is $5.00. Setup times are 6:00 pm to 8:00 pm on Saturday and 6:00 am to 8:00 am on Sunday. For reservations or additional information, contact RARA, PO Box 203, Winchester IN, or phone W9VJX at (317)-584-9361.

MARSHALL MI
MAR 20

The Southern Michigan ARS and the Calhoun County Repeater Association will hold the 21st annual Michigan Crossroads Hamfest on Saturday, March 20, 1982, at the Marshall High School, Marshall MI. Doors will open at 7:00 am for exhibitors and 8:00 am for buyers and lookers. Free parking, carry-in help, and full food service will be available at the school. Table space is $.50 per foot and will be reserved until 9:00 am. Talk-in on .07/.67 and .52. For more information, write SMARS, PO Box 934, Battle Creek MI 49016, or call Earl Goodrich at (616)-781-3554.

GRAYSLAKE IL
MAR 20

The Civil Air Patrol will hold its second annual spring hamfest on Saturday, March 20, 1982, at Lake County Fairgrounds, US 45 and 120, Grayslake IL. Donations are $2.00 and tables are $3.00. For more information and reservations, send an SASE to Captain Ed Rehm W9NXR, 637 Emerald Street, Mundelein IL 60060.

FORT WALTON BEACH FL
MAR 20-21

The Playground Amateur Radio Club will hold its 12th annual swapfest on Saturday, March 20, 1982, from 8:00 am to 4:00 pm and Sunday, March 21, 1982, from 8:00 am to 3:00 pm at the Okaloosa County Fairgrounds, Fort Walton Beach FL.

IRVINGTON NJ
MAR 21

The Irvington RAC Hamfest will be held on Sunday, March 21, 1982, from 9:00 am to 4:00 pm at the P.A.L. Building, 285 Union Avenue, Irvington NJ. Take the Garden State Parkway to exit 143 north 143B south. Admission is $1.00 and tables are $3.00. Refreshments will be available. Talk-in on .34/.94 and .52. For additional information, call Ed WA2MYZ at (201)-687-3240 or write IRAC, P.A.L. Building, 285 Union Avenue, Irvington NJ 07111.

JEFFERSON WI
MAR 21

The Tri-County Amateur Radio Club will hold its annual hamfest on March 21, 1982, from 8:00 am to 3:00 pm at the Jefferson County Fairgrounds, Jefferson WI. Tickets are $2.50 in advance and $3.00 at the door. Tables are $2.50 in advance and available at the door for $3.50. Parking is free and there will be plenty of food, beer, and prizes. The grand prize will be awarded at 2:30 pm. Talk-in on 146.52 and 146.22/.82. For more information, advance tickets, and tables, send an SASE to Horace Hilker K9LJM, PO Box 204, 261 E. High Street, Milton WI 53563.

COLUMBUS GA
MAR 27-28

The Columbus Amateur Radio Club will hold its annual hamfest on March 27-28, 1982, at the Columbus Municipal Auditorium, Victory Drive (US 280) at the south end of 4th Avenue (Highway 27), Columbus GA, from 9:00 am to 5:00 pm on Saturday and from 9:00 am to 3:30 pm on Sunday. Features will include a flea market, free overnight parking at hamfest site for self-contained campers, free coffee and hot chocolate, inside exhibits, and many prizes (including a main prize of a Radio Shack TRS-80 Mod III). Ticket donations are 6 for $5.00 or 13 for $10.00. To reserve inside table space at $3.00 per table per day, contact Jeannie Hunting K4RHU, 2701 Peabody Avenue, Columbus GA 31904, or call (404)-322-7001. Talk-in on .01/.61 N4BJZ/R. For additional information, write CARC, PO Box 6336, Columbus GA 31905.

ST. LOUIS MO
MAR 27-28

The Gateway Amateur Radio Assn. will hold ARCH '82, an official ARRL convention, March 27-28, 1982, at the Chase Park-Plaza Hotel, St. Louis MO. Advance tickets are $3.00. Features for the amateur radio operators and computer hobbyists will include a flea market, workshops, forums, major national exhibitors and dealers, prizes, ladies' activities, and a Saturday evening banquet. Special hotel accommodations will be available. For additional information, contact Gateway Amateur Radio Assn., PO Box 8432, St. Louis MO 63132, or phone (314)-361-4965.

MADISON OH
MAR 28

The Lake County Amateur Radio Association will hold its fourth annual Lake County Hamfest on Sunday, March 28, 1982, at Madison High School, Madison OH. Admission is $2.50 in advance (send an SASE before March 14, 1982) and $3.50 at the door. A table and display space is $5.00 for a 6-foot table and $6.50 for an 8-foot table. A table donation with a reservation will hold a space until 10:00 am. There will be plenty of free parking, commercial exhibits for ham and computerist, an inside flea market, door prize drawings hourly, and a main prize drawing at 3:05 pm. Hours will be from 8:00 am to 4:00 pm and vendors may set up at 6:00 am. Overnight accommodations are available within a 15-minute drive. Talk-in on 147.81/.21. Check-in on 146.52/.52. For further information or reservations, send an SASE to Lake County Hamfest Committee, 1326 East 349th Street, Eastlake OH 44094, or call (216)-953-9784.

GRAYSLAKE IL
MAR 28

The Libertyville and Mundelein Amateur Radio Society (LAMARS) will hold its annual hamfest on March 28, 1982, at the Lake County Fairgrounds, located at the intersection of Rtes. 120 and 45, Grayslake IL. Tickets are $2.00 in advance or $2.50 at the gate. Doors open at 8:00 am. Hot food and drink will be available, as well as 9-foot tables at $5.00 per table. Prizes,

CORRECTIONS

Readers who build the VE3CYC ATV project beginning on page 20 of this issue should include the following changes to make the converter more stable and less sensitive to antenna and feedline changes:

1) Install the MRF901 transistors from the foil side of the board.

2) Referring to Fig. 8 in the article, add a 68-Ohm resistor directly across the 440-MHz input cable on the circuit board. Solder one end of the resistor to the stripline near the center conductor of the coax. The other end of the resistor should be soldered directly to the circuit board ground foil.

Jeff DeTray WB8BTH
***73 Magazine* Staff**

The schematics in "TVRO Signal Source" (page 46, January, 1982), are missing a resistor between the +12-V terminal and the collector of the oscillator transistor. This part should be added to Figs. 1 and 2.

Tim Daniel N8RK
***73 Magazine* Staff**

Paul Grupp KA1LR's review of the AEA MBA Code Reader in the January, 1982, issue of *73* mentioned that a cure is available to reduce noise emitted by the unit's microprocessor. AEA informs us that this cure is very simple: Just put a bypass capacitor at the power-line input.

Tim Daniel N8RK
***73 Magazine* Staff**

including a synthesized HT, will be awarded to licensed amateurs. Talk-in on 146.94 and 147.63/.03 (Waukegan repeater). For reservations or tickets, write WA9HRN, Chairman, LAMARS, PO Box 751, Libertyville IL 60048 and include an SASE.

SEWARD PA
MAR 28

The Conemaugh Valley Amateur Radio Club will hold its fifth annual hamfest on March 28, 1982, from 8:00 am until 4:00 pm at the Sandy Bottom Sportsman's Club, Seward PA, approximately ten miles northwest of Johnstown on Rte. 56. There will be plenty of food and refreshments available, as well as many good prizes. Talk-in on 146.34/.94.

BALTIMORE MD
MAR 28

The Baltimore Amateur Radio Club, Inc., will hold the 1982 Greater Baltimore Hamboree and Computerfest on Sunday, March 28, 1982, beginning at 8:00 am at the Maryland State Fairgrounds Exhibition Complex located at exit 17 of I-83, three miles north of I-695 (near Baltimore) in Timonium MD. Admission is $3.00. Amateur radio, personal computer, and small business computer dealers will be featured at the dealers' display area. There also will be an indoor flea market, an outdoor hard-surface tailgate area, food service, free parking, hourly door prizes, and cash grand prizes. Talk-in on .34/.94 and .07/.67. For more information and table reservations, contact GBH&C, PO Box 95, Timonium MD 21093, or call (301)-561-1282. For a recorded announcement, dial (301)-HAM-TALK.

TRENTON NJ
MAR 28

The Delaware Valley Radio Association will hold its annual flea market on Sunday, March 28, 1982, from 8:00 am to 4:00 pm at the New Jersey National Guard 112th Field Artillery Armory, Eggerts Crossing Road, Lawrence Township NJ. Advance registration is $2.50; $3.00 at the door. There will be indoor and outdoor flea market areas, door prizes, raffles, refreshments, and FCC examinations. Sellers are asked to bring their own tables. Talk-in on 146.07/.67 and 146.52. For further information, write DVRA, PO Box 7024, West Trenton NJ 08628.

FRAMINGHAM MA
APR 4

The Framingham Amateur Radio Association will hold its 6th annual spring flea market on Sunday, April 4, 1982, at the Framingham Police Station drill shed, Framingham MA. Admission is $2.00. Sellers' tables are $8.00 before March 27, and $10.00 after that date. Doors will open at 10:00 am but sellers may begin setting up at 8:30 am. Radio equipment, computer gear, food, and bargains will be available. Talk-in on .75/.15 and .52. For more information, contact Ron Egalka K1YHM, 3 Driscoll Drive, Framingham MA 01701, or phone (617)-877-4520.

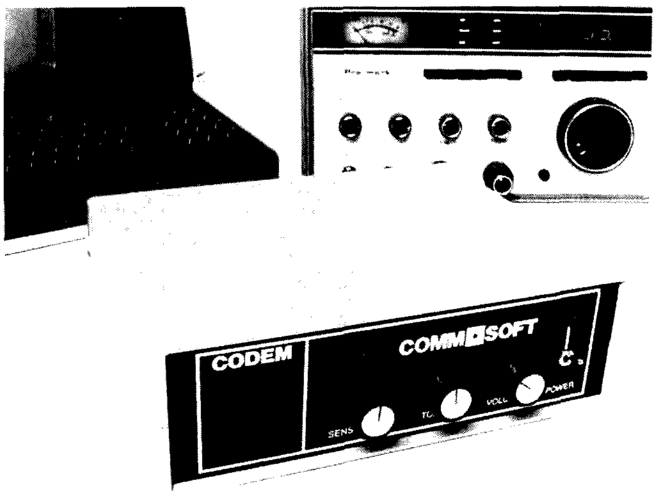
GRAND JUNCTION CO
APR 17

The Grand Mesa Repeater Society will hold the third annual Western Slope Swapfest on Saturday, April 17, 1982, from 10:00 am to 4:00 pm at the Plumbers and Steamfitters Union Hall, 2384 Highways 6 and 50, Grand Junction CO. Admission is free and swap tables are $5.00. Features will include an auction, door prizes, and refreshments. Talk-in on .22/.82. For further information, send an SASE to Dale Ellis KDØM, 588 Starlight Street, Grand Junction CO 81501, or call (303)-434-5981.

RALEIGH NC
APR 18

The Raleigh Amateur Radio Society will hold its 10th annual hamfest on Sunday, April 18, 1982, from 8:00 am to 4:00 pm at the Crabtree Valley Shopping Center parking area, Raleigh NC. Admission is $4.00; there will be a table charge for exhibitors and flea market displays. First prize is a choice of a Kenwood TS-830S transceiver or an Icom IC-251A multi-mode 2m transceiver with a Mirage B108 80-Watt amplifier. A hospitality room and party will be held the preceding evening from 7:00 pm to 10:00 pm. Talk-in on 146.04/146.64 and 146.28/146.88 both days. For more information, please contact Ken Boggs KB4RV, 8704 Cliff Top Ct., Raleigh NC 27612, or phone (919)-782-8646.

Two Keys To Perfect Code...



The CODEM: a universal CW interface for your personal computer.

$124.95

Here is an easy way to get your Morse code software on the air! The CODEM converts received CW audio to RS232 or TTL signal levels and RS232 or TTL signal levels to transmitter keying. The CODEM doubles as a code practice oscillator and CW regenerator. A sharp 800 Hz bandpass filter, AM detector and low pass filter are designed into the CODEM to provide outstanding noise and QRM rejection. Requires a 9 VDC power supply.

CODEM $124.95
9 VDC Power Supply 9.95
Shipping and Handling 5.00

CW89: a sophisticated split screen Morse code transceiver and trainer program for Heath computers.

$99.95

Transmit and decode CW with your H-8/H-19, H-89 or Z-89. This feature packed program incorporates 4–99 WPM operation, receive autotrack, a 1000 character pretype buffer, 10 user-definable messages, unique break-in mode, on-screen status, disk I/O and hard copy and a versatile code practice section. A comprehensive manual and prompt card are included with CW89. Requires HDOS, 32K RAM and hardware interface (such as the CODEM).

CW89 *postpaid* $99.95
CW89C H-8/H-89 Interconnect Cable for CODEM 24.95

Save over $14.00 with complete CW package for H-8/H-89.
Package includes CODEM, Interconnect Cable, Power Supply, CW89 Software, complete documentation and shipping.
CW89P $249.95

DX PREFIX LIST DX-1

The DX Prefix List is a custom-printed list of 367 separate places, including all of the current ARRL DX countries. Each location is calculated by pinpointing two locations. The DX Prefix List has 10 unique columns of information. First the list is arranged alphabetically and numerically by prefix. The next column contains the name of the country. The third column describes each CQ continent, while the fourth column lists the CQ zone. The ITU zone is listed in the fifth column. Columns six and seven give the short and long path distances in statute miles. The eighth and ninth columns provide bearings for short and long path. The rest of each line has a checklist to tally contacts, SSB or CW, and receipt of a QSL.

The DX Prefix List is priced at $6.95 (plus $1.50 shipping). Each listing is custom-printed for your station's location. For more information, contact *DX Prefix List, Jon Presley WDØEAO, Route 3, Box 117, Lebanon MO 65536.* Reader Service number 477.

QUAD BANDER ALL-MODE TRANSCEIVER

Trio-Kenwood Communications has announced a unique new radio, the TS-660 "Quad Bander," an all-mode transceiver designed for operation on 6, 10, 12, and 15 meters. The unit features built-in dual vfo's, a five-channel memory, and memory scan. Modes of operation are FM, SSB (USB), CW, and AM.

The TS-660's rf output power is 10 Watts on SSB, CW, and FM, and four Watts on AM. The radio operates from a 13.8 volts dc power supply. Kenwood's list price is $699.95. Additional information may be obtained by contacting *Trio-Kenwood Communications, PO Box 7065, Compton CA 90224.*

COAXIAL ANTENNA

Power Gain Systems has announced a coaxial antenna that offers a new approach to the construction of the well-known double-bazooka dipole design. The antenna has the broadband, low swr characteristics of the bazooka and features injection-molded plastic construction for weatherproofing, strength, and durability.

The antenna comes with an SO-239 fitting and is ready to accept any length of 50-Ohm feedline without the necessity of a balun or tuner. Available for 80 through 10 meters, the Power Gain Systems coaxial dipole costs between $34.95 and $39.95. For more information, contact *Power Gain Systems, 1007 Cypress St., West Monroe LA 71291; (315)-325-4754.* Reader Service number 476.

10-kHz-TO-30-MHz TUNER

The new Signa/Match from Grove Enterprises is a state-of-the-art frequency-selective tuner designed to optimize impedance matching between 10 kHz and 30 MHz. It will reduce, and in many cases remove, receiver intermodulation, images, and front-end overload. Background noise is reduced. VLF signals you never dreamed were there come roaring in loud and clear.

Kenwood's Quad Bander all-mode transceiver.

Front-panel switches allow instant selection between two antennas and between two receivers (or two antenna inputs to one receiver). Matched rotary switches permit the listener to peak signal strength of the frequency of interest, while a main tuning dial provides sharp resolution of the final signal. Priced at $99.95, Signa/Match comes complete with instruction manual and all interconnecting cables. For further information, contact *Grove Enterprises, Dept. C, Brasstown NC 28902; (704)-837-2216.* Reader Service number 478.

3.3-METER DISH

The Director III satellite receiving antenna from International Satellite Video Corporation utilizes space-age materials and technology for a unique lightweight design. The 3.3-meter dish has a high-efficiency Cassegrain (dual reflector) feed system which places receive electronics at the rear. The unusual perforated aluminum reflector surface with approximately 80% open area is almost impervious to wind.

The Director III is supplied with a correcting polar mount so that satellite selection requires only one adjustment. The complete system may be shipped by UPS. Installation time is approximately 2-3 hours. Options include programmable remote sat-

Grove Enterprises' Signa/Match.

The Director III 3.3-meter dish.

ellite aiming and electronic polarity selection. The Director III is available from *International Satellite Video Corp., Box 5685, Orange CA 92667; (714)-998-6080.* Reader Service number 481.

HF SWR/WATTMETER

MFJ Enterprises is introducing its new MFJ-816 low-cost HF swr/wattmeter for the 1.8- to 30-MHz range. Features include toroidal pickup for uniform sensitivity over the entire HF frequency range, dual ranges (30 and 300 Watts), and a two-color meter scale.

The MFJ-816 HF swr/wattmeter is priced at $29.95 (plus shipping and handling). For more information, contact *MFJ Enterprises, PO Box 494, Mississippi State MS 39762; (800)-647-1800.* Reader Service number 479.

SATELLITE TV RECEIVER

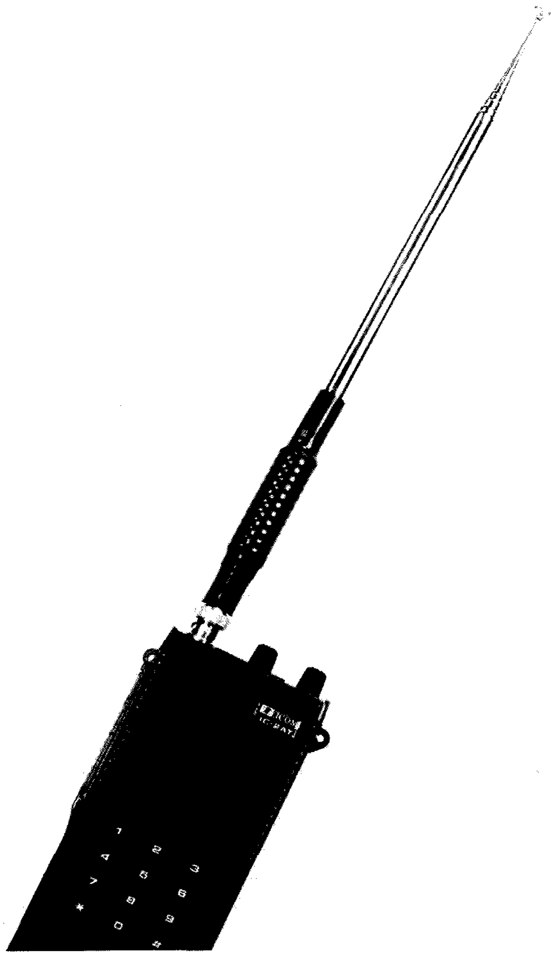
Telecom Industries' new TIC 1240 satellite television receiver now provides improved AFC and scan tune (for fast and easy satellite locating) as standard features. Improved threshold combined with better video resolution provides picture quality found in receivers twice the price.

The dual-conversion downconverter (204A) mounts directly at the LNA output while providing +15 volts through the N connector as well as externally. Improved environmental characteristics include hermetically-sealed connectors and temperature compensation for a virtually drift-free picture. The TIC 1240, with a retail price of $995, is available from *Telecom Industries Corp. 27 Bonaventura Drive, San Jose CA 95134; (408)-262-3100.* Reader Service number 482.

5/8-WAVE HT ANTENNA

The Tuned Antenna Company has announced a two-meter 5/8-wave antenna, the Super Stick II, for use on hand-held radios. The Super Stick II, when fully extended, offers 6 to 9 dB of signal output over traditional rubber duck antennas. All connections are soldered and copper-plated for years of troublefree service. The Super Stick II has been designed to operate when collapsed, giving performance equal to or better than a rubber duck antenna.

Super Stick II is available with BNC, 5/16-32, F, TNC, or PL-259 connectors, at a suggested retail price of $19.95. For more information, see your local ham dealer or contact the *Tuned Antenna Company, 9520 Chesapeake Dr. #606, San Diego CA 92123.* Reader Service number 480.



The Tuned Antenna Company's 5/8-wave HT antenna.

LETTERS

TO BE A DXER

I enjoyed very much the interview with the Colvins of Yasme fame in the October, 1981, issue of *73*. Many DXers I know would give their right 3-500Z to go on a DXpedition like those the Colvins are famous for. To be a DXer one must incorporate feelings about being on the other end of the microphone. Some day I'll be there, but for now, CQ DX.

Michael Weber WB8RDN
Cincinnati OH

EARTH PEOPLE

I was recently rummaging through *Sailing*, a new book of whimsical nautical definitions by Henry Beard and Roy McKie. Therein I encountered the following unlikely commentary: "Citizens Band Radio—Part of a government study of terrestrial radio emissions to determine if intelligent life exists on Earth. None has so far been detected." 10-4!

Robert Rice WB7VIP
Oak Harbor WA

SING ALONG

Kit K5KL and *73 Magazine* are to be congratulated for the fine story, "Update your CW Music Keyboard," In the December issue. It is hoped that this article will motivate others to write about their experiences and improvements.

CW music keyboards ("This Station Plays Beautiful CW," *73 Magazine*, February, 1979) are playing from Auckland (Fred ZL1ALP/MM) to Vienna (Hans OE1WH) with many in between. My mail indicates that others also could write interesting stories and additions and improvements for the CW music keyboards. Topics mentioned to me include: hard copy, expanded memory, speed indicator, replacing the 4078, use of the 3351 and a single-voltage power supply, solving propagation-delay problems, Crom was wrong to badmouth wirewrap, and many others.

If anyone still has a problem, be advised that I still answer all letters. Please include an SASE.

Russell C. W. Crom AG9N
Mt. Prospect IL

WATCH IT!

In the article, "Ham Shack Design for Beginners," a very dangerous situation could develop if a reader followed the author's advice. I am referring to questions two and three that deal with fusing both the hot and the neutral.

In the National Electrical Code, 1981 edition, Article 240, Section 20, it states: A fuse or an overcurrent trip unit of a circuit breaker shall be connected in series with each ungrounded conductor.

Section 22 of Article 240 goes on to say: No overcurrent device shall be connected in series with any conductor that is intentionally grounded.

Besides being against the Code, the article's suggestion could pose a serious hazard. If the neutral fuse should open, the equipment, though not operational, would still be

energized and a possible hazard.

Although I do not agree with the author's suggestion that the neutral be fused for lightning protection, it can be done according to the Code by using a special breaker that disconnects the neutral simultaneously. This is commonly used in service-station wiring.

Gary Strong KB0UI
Auburn KS

MAJORITY OF ONE

I am firmly opposed to any type of no-code license on any band. You have constantly criticized the League for forcing incentive licensing upon us despite the majority of active amateurs being firmly against the whole concept. Now you have somehow arrived at the idea that we need a no-code license and openly admit you will push for it despite the wishes of the majority of amateur radio operators. I find this contradictory, to say the least.

You also state that amateur radio needs leaders. Well, that is true, but we need leaders who are responsive to the wishes of the majority of all operators, not to the wishes of "thousands" of would-be amateurs who want to be licensed at their own terms. We also do not need any self-appointed leaders who decide single-handedly what is good or bad for amateur radio.

A true leader should always work with the majority to develop new ideas and accomplish needed improvements. This is a democracy, and that's the way it works.

Charles E. Daum WA4YZF
Lutz FL

Charles, aren't you a little confused between what is a leader and what is a follower? You seem to be looking for a leader who won't lead, but who will do what the majority wants . . . if anyone really knows what that is. When the ARRL proposed the plan to get 85% of the hams off phone, they claimed that only 20% of the members were opposed, so perhaps they were representing the majority. Since we have no elections in the ham field for leaders, all you are ever going to get are self-appointed ones. Now, if you want leaders without any ideas and with no interest in improving amateur radio . . . which is what you seem to be plugging for . . . by golly why not back all of those you see around? I opposed the ARRL plan to return to the prewar band system because I felt it would create severe problems . . . and I pointed them out. I did not oppose it as a representative of amateur radio or a leader presuming to represent the majority. In the present case, where I feel that we have had exhaustive proof that the code requirement does not keep out the severely psychotic and where there is a good reason to believe that a license based upon technical competence would clean things up, I am going to push for that, majority or no. I expect to find a wide variety of the confused, the apathetic, the psychotic, and reactionary hams fighting any changes. I also expect to find the more intelligent hams looking at the situation, weighing the evidence . . . and deciding that my ideas are worth a try. It would be difficult to have any new system tail worse than the one we have now. Charles, I have never been responsive to the majority and I'm not going to start now. When I perceived that FM and repeaters would be fantastic for amateurs I went ahead and published hundreds upon hundreds of articles . . . I published book after book . . . and held FM symposiums . . . plus a monthly repeater newsletter. The majority of hams hated it and raised hell over this. I stuck to my guns and today FM is the most popular aspect of amateur radio by far. Now the majority sees it my way . . . and perhaps now I am a leader in their eyes. Well, when I was one against the crowd, was I a leader then? You don't want a leader, you want a wishy-washy namby-pamby puppet and I wish you a lot of luck in finding one. Come to think of it . . . you won't have much trouble, for just such a sterling man seems to be in the offing. If you really want to be in the large group following a puppet, your opportunity is at hand . . . but leave me out of that.—Wayne.

HOOEY

In an effort to sell magazines and memberships, the ARRL drafted almost every CBer onto the ham bands. And now you want to drop the code requirements and draft everyone else, probably to sell magazines also. If the Aircraft Owner's and Pilot's Association took the same position, we would have the air space completely full of aircraft.

Mister Green, you need to understand that amateur radio is a hobby, not a business. And a *no-skills* license is not the answer to poor circulation. There are many hams that have dropped *73* (like myself) because of your "license everyone" position. In the future, I intend to plug you on the air and at meetings as the man who "sells magazines at the expense of amateur radio." Regrettably, your publication is a very good one. But it is not worth the damage you are doing to amateur radio.

"Butch" Rogers K3RYI
Wichita KS

Butch, you are full of guano. Oh, I've heard that brand of baloney before . . . about the crass commercial interests trying to get anyone and everyone into hamming in order to make dirty money. Well, it's hooey. ARRL did not draft CBers into amateur radio. If you would put what is left of your brain into gear you would recognize that anyone with any kind of an interest in radio communications . . . which is what I think we're looking for in hams . . . has to be a fruitcake not to try out CB for starters. If there had been anything like that when I got into ham radio, you can bet I would have been using it. So putting down someone for starting off with CB is ridiculous . . . a redneck reaction. No one that I've seen is trying to draft people for amateur radio with less abilities than now . . . indeed, it would be difficult to have a lower entry requirement than at present, considering some of the turkeys we have been getting into amateur radio of late . . . in case you've turned on a radio. I . . . and 73 Magazine . . . are proposing a much tougher type of license exam than at present . . . one which might keep some of the pigs out of the ham fraternity. I think we've seen more than enough proof that a code exam keeps out little and that some other means of separation of the sheep from the goats is needed. I believe that a technical exam, given by a ham club, one which follows a series of technical classes given by the club, will be a better system and will result in fewer obscene-mouthed nerds getting licenses. It is you who are doing the really serious damage to amateur radio . . . not those of us who are trying to clean it up by setting better standards for licensing.—Wayne.

NOT DUMB

I fully agree with you in reference to your editorial in December's *73 Magazine*. I would very much like to have a ham license but I have trouble with the code portion of the test. I do not consider myself a dumb person, but I seem to have a mental block concerning code. I have used your tape and others, but it seems that when I learn the sounds, I cannot get words out of them. Anyway, keep up the good work on *73 Magazine*, knowing that I for one will not drop my sub until your mag goes to all computers. I use computers in my work, but still do not own my own personal one. As I live 90 miles from Denver, I do not get even one television station and so subscribe to about 70 magazines at this time. I must say that the most-read and looked-at magazines are the ones put out by you. Keep up the good work.

You can also be sure of my support concerning a non-code license. Basically, I would like a license to be able to use ham radio in emergency situations. To be honest, the way the bands sound I do not have any interest in DX. It seems that most stations are interested only in a signal report and a QSL card. At least as far as US stations are concerned. In case you were wondering, I have a business license and so do use radio in the course of my everyday work—which is running a ranching business. Well, anyway, keep up the good work with your magazines.

David L. Andrews
Granby CO

David, a contact is whatever you make it. Whether you are talking on two meters, on 75 meters, or working DX, the type of contact is up to you. Oh, if you call in on a DX pileup or on a list operation, you know you are in for a QSL-type of contact. But if you are really interested in meeting people and talking with them, they are there, and they are as anxious to talk with you as you with them . . . if you give them the chance. I've had hour-long rag chews with even the rarest

of DX, finding things of mutual interest to discuss. I've found that most hams in rare spots are pathetically eager to talk. They are always running up against hams who want their QSL for a country, a prefix, etc., and it gets to be an expensive bore in a short while, driving many of them off the air. The more you can get into rag chews with these chaps, the more they will enjoy amateur radio . . . so you are performing a public service at the same time that you are enjoying yourself. You know, not every ham in the world lives and dies over the ARRL Honor Roll, or even over a DXCC certificate. Some are in it for the fun of talking . . . so give them a chance. You'll rarely hear me fighting the pileups. I tend to look for longer contacts, talking about how it is to live where they are, what there is to see, the skin diving, the photography, things like that.—Wayne.

WHERE'S ELMER?

As an aspiring Novice, I naturally subscribe to the better publications such as *73*. I read and re-read each issue, with the hope that I can somehow begin to make sense of some of the articles and projects. I have been a kit builder for years (Heath), and just recently I decided to venture again into the world of amateur radio.

While I have received much information from *73*, I think that many of the construction articles go right over the heads of the less sophisticated in electronics construction. Many of the equipment designs would be fantastic for the Novice just getting started, but the schematics scare them away. If the projects were presented with circuit board layouts with parts placement and wire directions, that would be a real boon to the Novice, both educationally and in the pocketbook.

There is one other problem that I would like to discuss with you briefly. As an "outsider" looking to get in, I have noticed a few idiosyncrasies of the amateur operator that perhaps have escaped the eye of those "inside."

I use the words "outsider" and "insider" because this is the way I have been made to feel by some of the amateurs I have come in contact with. They have made me feel as though my questions were stupid. They seem to lack the time to answer questions, and can't be bothered with a person who can't read schematics but only Heathkit™ diagrams. It would seem that unless you are a 25-wpm Extra with a 2-kW station with super quads, membership in clubs is discouraged.

Your editorial in the December, 1981, issue of *73* was of particular interest to me. You bemoan the loss of potential amateurs, the loss of new technical manpower, etc. You also stated that the youth of our nation should be made aware of the future in electronics and the fun of ham radio, through local clubs. This reminded me of when I was 16 and my imagination was first sparked by the lure of amateur radio. I was met with the same indifference as I am experiencing now, 20 years later. I had forgotten my bad experience and was just reminded of it recently when I again attempted to join the fraternity—or should I say clique.

I don't mean to sound negative, but it is easy to see why most potential Novices are turned away from amateur radio. The amateurs should be looking more to themselves rather than rattle sabers at the FCC. License requirements are tough, but not insurmountable. But if left to the clubs, I dare say even fewer would be licensed, at least through my experience, anyway. For the last 7 months I have been searching for that elusive "Elmer" I've heard about, who is always ready, willing, and able to lend a hand. Instead, I've received indifference, ambiguous information concerning membership in most clubs, infrequent or non-existent schedules for meetings, and what seems like a total lack of interest in helping a newcomer.

No longer a child, I refuse to give up this time. I'll make it on my own, through your excellent tapes and books. Maybe someday I can offer myself as an Elmer and perhaps revive what appears to be a lost tradition.

William J. Naughton, Jr.
Philadelphia PA

SURVIVAL

I have just finished reading Marvin Solomon WB8VNP's letter, "Survival," which appeared in the December, 1981, issue of *73*. I agree with his concern for the caliber and amount of scholastic training our children are receiving, but I think it goes further back than high school, all the way to our grade schools. Committed teachers are rewarded by moving them up into administration and replacing them with less competent educators who are interested only in the financial gains and not the education of our children. I'm not saying they are all like this, but the percentage of teachers who would rather promote a child with whom they had trouble instead of assuming the responsibilities of their jobs, namely to teach them the basics, is way too high!

I have a business where I'm in constant contact with children from grade school to college (I'm a barber) and it's amazing how many cannot even fill out a check properly, let alone do the basic fundamentals of math.

I have had a running battle with the school system here for almost twenty years, with four children in different levels of schooling. Sometimes I'm not sure whether I'm winning, but I urge every parent to be aware of the quality of schooling his children are receiving and if there is the smallest doubt that they are getting an adequate education, fight. Don't let them tell you what to do—you tell them. Otherwise the gap will get even wider.

Barry Vierra WB6GZK
Fair Oaks CA

You're right, Barry. Education has changed a good deal in the last 50 years. In the third grade I was taking courses in art appreciation, complete with the fundamentals of composition. This was invaluable to me when I got into photography . . . and later, when I went to work as a television cameraman, I was the only one in the crew who had had this sort of training. They taught us how to read music in the third grade, too . . . later valuable to me when I started singing in church and then in choruses. As far as I know, those subjects are long forgotten in most schools. Then there was a class in recognizing classical music, another one I'll bet they've stopped. That was in Brooklyn, New York, of all places . . . in the public schools. The art and music classes were in New Jersey. Later, in high school, the art classes were even better. My mother got so enthused by them when she went to the same high school that she went into art for a career. There is much to be done about education. If we can't get the schools to improve we still may be able to pull it together with video/computerized teaching systems which will be along in a few years.—Wayne.

CRIMINAL BAND?

After reading the letter by A. E. M. Spence VE7DKY, I felt compelled to voice my disagreement. First of all, I did not appreciate the insinuation that most of the lids on the air were from the 4th and 5th call areas. Since being licensed in 1976, I have heard very few hams from the 5th call area that would fall into the lid category. As for the New Mexico hams, I believe them to be of the highest caliber in the country.

The other statement that bothered me was the one on wanting the rest of the "Criminal Band" fraternity on the air. First of all, the proper name is "Citizens Band." Second, I as well as probably most of the amateurs don't want the average CB operator in the ranks, but there are a lot of CBers who would be an asset to the Amateur Radio Service. After all, they are humans just like everyone else, and everybody must start somewhere.

I got my start because of CB, and I don't consider myself a lid. I have an Advanced class license for which I *worked* very hard, and am into VHF, HF, and into the extra modes of RTTY and OSCAR. I am very active in building, and work with integrated circuits. I am also into computers.

Now, if it were not for CB, I probably would never have entered the world of amateur radio and electronics. Now, of course, I have a very marginal use for the Citizens Band radio service, but let us place credit where credit is due.

I do think that Mr. Spence should do a re-evaluation of the entire basis of his opinions.

Stan Gantz WB5TGL
Silver City NM

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randallstown MD 21133

One of the most enjoyable and at the same time most rewarding aspects of writing this column is answering questions posed by readers. Because of the volume of mail received and my rather tight schedule, I am not always able to answer each one individually. Letters containing requests for a specific circuit or part are often unanswerable when received, and normally are held until such time as the requested information becomes available.

On the other hand, questions of general interest, such as those relating to RTTY principles or techniques, frequently wind up here in the pages of *73*. Not everyone is an expert, or even well versed, in everything. Questions from novice RTTY users as well as meaty tidbits from old pros provide an interesting and varied fare for the readership. Hungry? Let's see what's on today's menu.

Emil Guerrero, a "prospective ham" living in Portchester, New York, wants to add RTTY to his SWL (shortwave listening) shack. Emil notes that he is "no speed reader" and is interested in using a code converter to allow display of ASCII data on a Murray (Baudot) machine. Specifically, he asks about the feasibility of using a Murray printer running at 60 wpm (45.45 baud) to copy an ASCII transmission being sent at 150 or 300 baud.

Converting the eight-level ASCII to five-level Murray is no problem, Emil, and several hardware and software schemes have been covered in this column and within the pages of *73* over the past few years. The problem comes in when you try to build the reservoir.

"Reservoir," you ask? Well, it breaks down like this. ASCII transmission coming in at 300 baud, the most commonly used speed, represents about 30 characters every second. In, let's say, the first minute, that represents about 1800 characters. On the receiving end, that teleprinter is able to handle five-level input at 45.45 baud, which represents about six characters per second, or about 360 characters per minute. Not counting slop-over, this represents about 1440 characters per minute that must be stored. In a ten-minute broadcast, you would have to provide a reservoir, such as with a computer-style read/write memory, of some 14,400 characters. That's roughly 14 kilobytes! Now you need some means of stuffing data into that memory, pulling it out, keeping track of where you are, and doing a code conversion (ASCII to Murray, remember?) all at the same time. You need a computer.

Now, it can be done, and certainly individual characters can be converted from one code to another without all this hassle. But in order to receive automatic transmission, that is, transmission at machine speed, a buffer and some machine "smarts" are needed. Hopefully, some of the articles published in the past will help.

Emil is not alone, by the way. A similar letter was received from Larry LeMone K7IHI, out in Provo, Utah, who is also interested in such a conversion scheme.

Along the same line, but with an interesting variation, comes a letter from Curt Heuberger K1CH in Seekonk, Massachusetts. Curt is interested in using an IBM Selectric® typewriter for a RTTY I/O device. I see no reason why such a code conversion could not be implemented using a Murray-to-correspondence scheme similar to those which implement ASCII on the Selectric. I am using such a scheme here with an unpublished program that turns an I/O Selectric into a "smart" printer. It would be simple to take a scheme like that and change the code tables to convert to Murray rather than ASCII. Curt mentions that he has the "fixin's" for a small Z-80 computer sitting on the shelf. Either that or a small single-board computer like the "Kilobaud Klassroom Komputer" described here a few months back would be ideal to implement a RTTY Selectric system.

Emil, along with Richard Flink WB2SOU, out in Hillsdale, New Jersey, wonders about where to find stations broadcasting weather or press information. I again refer to Tom Harrington's book, *World Press Service Frequencies*, available from the *73* Radio Bookshop for $5.95 (order book number BK1202). This book, along with its periodic updates, comprises one of the most complete listings I have seen and includes a wide spectrum of international RTTY stations. It is, by the way, only one of the good books to be found on a tour through the Bookshop.

Merging computers and RTTY continues to be a popular topic. George Gadbois W3FEY is confused as to why, with several of the schemes I have described to input RTTY into a 6800 computer, I have resorted to a software UART rather than configuring the serial port into the five data bits needed for Murray code.

Well, George, this all relates to the type of chip used for input into this series of computer. Rather than a general-purpose UART, the 6800 series of computers—that is, most computers based on the Motorola M6800 CPU—commonly use a Motorola 6850 ACIA (Asynchronous Communications Interface Adapter) chip. The ACIA is more "powerful" than a UART in that it allows more control to be passed in and out of the computer and interfaces with the bus and serial communications line very well, but lacks the ability to be configured in other than a seven- or eight-bit format.

It is this failing, as it were, that forces us into using an alternate scheme, other than the serial ACIA, that is, to input five-level Murray into a 6800 computer. There are two ways to go. Either use a UART, which means building an interface board and software, or use a parallel port, which involves only new software. For a frugal fellow like me, the "software UART" is the logical choice.

Once selected, the software approach suddenly offers all kinds of other advantages. Speed changing or code changing is trivial to accomplish. Auxiliary lines are available to key the transmitter, turn on lights, or brew the coffee. All kinds of nice things fall into place, and you even save a few bucks: Neat!

It is for this reason that another scheme, posed by Paul Pennington of Martinez, Georgia, will fall through. Paul is using an SWTPC 6800 computer with a video board display and a modem connected to the computer's former input board, an ACI-based interface. Paul feels that feeding receiver audio into the modem and then through into the ACIA for input would be a viable way to implement RTTY on a shoestring.

There are a few problems with this idea, no matter how attractive it seems. First of all, the common modem receive frequencies in originate mode, the "normal" state of affairs, are mark = 2225 Hz and space = 2025 Hz. Contrast this to the RTTY "standard" of mark = 2125 Hz and space = 2975 Hz used on VHF links. Not only is the degree of shift different (200 Hz vs. 850 Hz), but the direction is wrong also. Now, if you were on HF and used the wrong sideband to tune in a 170-Hz shift signal, you might get the modem filters to recognize the signal, but then another problem arises.

The usual mode of transmission on amateur circuits is still five-level Murray, and here you are with that ACIA board just as tied as ever to seven- or eight-bit codes. Sorry! I am afraid that you would either be limited to receiving ASCII or would have to replace the ACIA with a UART in order to input the Murray code unmolested. As a kluge you could try to interface the modem to the one-bit parallel port software UART we have been talking about, but I can't recommend that.

The other problem is in using that modem itself. The extra bucks that a RTTY demodulator costs buy quite a bit in selectivity, function, and features when compared to a landline-style modem. You might look into a small demodulator, such as the iRL FSK-500 highlighted here a few months back, to complete a RTTY station at minimal expense.

Boy, this has been a depressing column, so far! All I have done is tell this fellow or that one that this scheme or that will not work. How about something encouraging?

Nicholas Oland W3DSE of Reading, Pennsylvania, is looking for a way to convert a surplus ASCII video terminal to Murray. Nick states that he is

not looking for buffers or other bells and whistles, but just for a straight ASCII/Murray scheme for manual operation.

Well, as long as the display terminal is able to operate faster than the input, as it would be with a 300-baud terminal receiving 45.45-baud code, the reservoir problem detailed above would not be a factor. Similarly, I presume few of us can type at machine speed for any length of time, and if you can, you could not go any faster on an old Model 15, so let's accept that constraint also. Fig. 1 is a block diagram of what you need, a simple hardware ASCII-to-Murray duplex converter. Several such schemes have been published in *73 Magazine* in the past.

Nick also relates difficulty in finding specialized chips, UARTs, and the like needed for building projects such as this. I have found that most of the firms who advertise right here in *73* do a fine job of providing just about any imaginable part. When I have needed a particular chip or part that is not listed in their ads or catalogs, a phone call or letter to selected firms will usually turn up one able to supply the item from stock. Not all stocked items are able to be listed, you know.

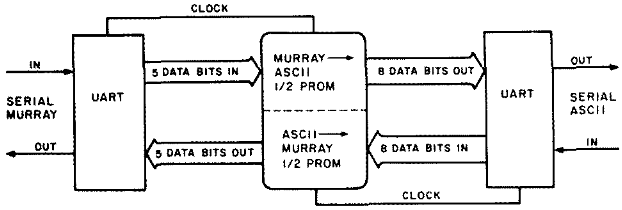


Fig. 1. ASCII/Murray conversion block diagram.

Above all, know the firm with which you deal, either through a friend's recommendation or with the endorsement of the publisher of the ad. Don't send cash through the mails, and keep a copy of your order should problems develop later.

Next month is April, and every year at this time I get the urge to write something, shall we say, unique. Want to find out? Don't miss next month's RTTY Loop!

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 8

cians, and electronics experts. Well, the recent emphasis on skipping theory in the getting of a ham ticket, with the use of the ARRL Q&A and Bass cheat books instead of an understanding...using only an ability to copy code as the filter...has reduced our ranks to a mere handful of technicians and electronics experts. By using the code as the only serious test...if you can call five words per minute serious...and throwing out any real need for technical knowledge, we have thrown out most of our value to the country...and to ourselves.

Yes, a few of you reading this have taken the trouble to use the *73* license study course and you have a good understanding of the fundamentals of electronics. You are in the minority, sad to say. And how many clubs take a half hour or so at the beginning of their meetings to run through some aspect of radio or electronics theory? Maybe a dozen out of several thousand.

Reservoir of operators? Sure, but for what? Not for any military need today. The military rarely uses code today. They use phone for local communications and automatic encrypted systems for longer ranges. Fortv years ago, it took a few months to train a ham to be of value to the armed forces. During WWII, 80% of the hams went into the services and helped out... mostly as technicians, not as Morse operators. That was before RTTY was really invented. Once that was an accomplished fact, the use of Morse virtually disappeared. Today, with computers so small you can carry them in your shirt pocket, no one needs a hand key or an old Teletype™ clunker. Computers can be used to write messages and then they can be plugged into a communications system and the message can be transferred almost instantly, anywhere.

Indeed, I've recently written about a system which I suggest that amateurs start developing, using currently-available technology and equipment, which would allow us to communicate at 8,500 words per minute. With some encoding, that can be upped to 26,000 words per minute.

Some reservoir we are at present! It could take a couple of years to train hams to cope with today's military technology.

Okay, on to 97.1(e), the last of the reasons for amateur radio to exist as a service. International goodwill. Boy, can we stand to do some work on *that* one. I suppose there are a few ops in foreign countries who feel goodwill when dumped on by a pileup... damned few. And how many of the DX ops really enjoy our 5,000-Watt Honor Roll (the irony of *that*)—ops wiping out every new and rare country which comes on the bands? Is it going to be claimed that an exchange on CW of signal reports and a handle are really generating goodwill? Don't make me laugh so hard that I break open my 40-year-old appendix scar.

Look here, don't get mad at me for simply stating the facts of life. If you don't like the facts, do something to change them ...don't beef at me for having the gall to state the obvious.

Now, you are not going to have any problem finding a whole raft of hams who swear by the Morse code...which I admit is extremely useful when you want to blink your eyes in code (would it be faster in ASCII?). But how many of you are going to try to tell me that you honestly believe that the code requirement has kept out the dingbats? Brother, we are up to here in psycho cases, so don't tell me about keeping out the undesirables. When I see four-year-old kids passing the code test and getting a ham ticket, I have trouble not being terminally sarcastic when I hear claims about it keeping our bloodline pure. If you are lucky enough to be in an area where two meters is sane, please get Bill Pasternak to send you some tapes of two meters in Los Angeles. You'll never be the same. A zoo.

And I'm getting a little sick of hearing that I am for opening the floodgates to the loonies. Those gates have been open for years. I'm for making amateur radio a technical hobby...with required courses in theory given by clubs...and damned good exams given by the same clubs. Maybe we can stem the tide of CB outcasts.

By golly, *that* felt good. Well, now back to being mild-mannered, lovable old Wayne Green.

CODE COURSES THE PITS

A recent call from Larry Horne, who runs a school in New York which teaches code in a matter of a few days, preparing people for their ham tickets, brought out that tests of the many code cassette courses on the market had shown most of them to be disasters. One of the very worst, oddly enough, was one of the best selling, put out by a national ham organization. And, yes, the organization knows that the course is bad and is losing us hams by the tens of thousands, but apparently it feels that it is too much trouble to change it... and, after all, it is selling well. Dealers, interested in making a buck any way they can, allow this travesty to be sold. Pity, when there *are* some very good code courses available.

Larry is running some tests for the Coast Guard to show them how fast some of the modern systems are...systems such as the *73* Code Course. The Coast Guard, which I understand has been quite hostile to amateur radio in the past, has been putting their trainees through a five-month, forty-hour-a-week course in which about 20% get to a speed of 18 wpm. Then, after a year on the job, another 20% qualify for 18 wpm.

60% wash out. So much for the old code-teaching system.

Would you believe that it is possible to start rank beginners out at 20 wpm? In fact, tests are being made at 35 wpm for starters...yes, from the very start. And the tests are very promising. It seems it is no more difficult to get the feeling of the pattern of a character at 35 wpm than it is at 5 wpm. Better; instead of setting up a lookup table in one side of the brain and transferring the sound pattern from the other half of the brain for comparison, everything is done in the same side of the brain. This avoids the old plateau syndrome...a disaster which has washed out hundreds of thousands of prospective hams.

Tentative tests seem to indicate that women, in particular, benefit from this avoidance of the left to right to left brain-shuffle problem. Perhaps it is the more intense competitive dedication of men that finally overcomes this mess rather than anything inherent. At any rate, setting up a learning system which uses one side of the brain only cuts the learning time to shreds, avoids much of the agony and sweat, and almost guarantees 100% success for anyone trying. It's almost fun...but not quite.

I'd like to see how far this concept can be carried. I don't see any reason why code can't be taught using this system and starting out at 50 wpm...and possibly even up to 100 wpm. Once you stop having to send the signals back and forth through the slow brain circuits and set up an operation which is largely done in the super-fast subconscious part of the brain, we're not sure what speed can be attained.

So, if you are asked about code-learning systems by newcomers, their fate is in your hands. You can recommend the best sellers...and doom them, for the most part...if not to failure, at least to agony. Or you can give them a real boost by recommending one of the only two (as far as I know) courses on the market which train the brain for automatic character recognition. That's the *73* Blitz Code Course.

IT'S UP TO US!

Don KA7DTP sent me a copy of an article from *Science* which said that the government has now terminated all efforts at listening for alien radio messages. The $2M a year program was shot down by Senator Proxmire, saying that, "It's hard enough to find intelligent life here In Washington."

NASA scientists were building a multichannel spectrum analyzer to detect non-random signals from space. That's down the tubes now and, according to a scientist from Stanford University, "The important contacts with extraterrestrial life will be left to radio hams." That's hardly a mandate, but if any readers are interested in pursuing the project, I can assure you that *73 Magazine* is most interested in providing the needed communications via articles and news.

What a pity that Sam Harris W1FZJ/KP4, who was a scientist on the big dish at Arecibo, isn't around to help get this started. Sam was one of the real ham inventors and pioneers...which is how he got the job at the research laboratory in the first place. It was Sam who built the first working parametric amplifier. He built it at home for use on six meters, and when I published the article on it most readers thought it was a humor piece. Who ever heard of feeding an oscillator into an amplifier?

As a piece of further bad news for VHF old-timers, Sam's wife, Helen W1HOY, a true pioneer on six meters, passed away a few weeks ago. She was living in Puerto Rico in Arecibo. Both Sam and Helen will be missed by all of their friends...and by future hams who will not benefit from the many inventions that Sam might have produced if he had lived.

Getting back to listening for signals from space...I'm interested in some articles on this and perhaps an organization of ham pioneers to systematically scan space for coherent signals. With the recent progress in digital circuits, we should be able to come up with some relatively inexpensive circuits for detecting non-random signals. The next step is to choose the best frequencies...get all of the help from the satellite TV technology we can for dishes, low-noise front ends, downconverters...and start listening.

NASA and Senator Proxmire...I say that amateurs accept the challenge. Now, let's hear it from those readers who want to be involved with this project.

OSCAR ORBITS

The tables of orbital information for OSCARs 8 and 9 were prepared with the assistance of Project OSCAR, Inc., PO Box 1136, Los Altos CA 94022. Due to the low orbit of OSCAR 9, its orbit is changing rapidly, making accurate long-range orbital predictions very difficult. Therefore, the OSCAR 9 information in these tables may be in error by several minutes and several degrees of longitude.

THE RUSSIAN SATELLITES

The last days of 1981 were exciting ones for amateur satellite fans. On December 17, the Soviet Union simultaneously launched six new Radio Sport (RS) amateur radio satellites, designated RS-3 through RS-8. The new birds were placed into orbit by a single launch vehicle and each takes about two hours to orbit the Earth. Although they are in similar orbits, the RS satellites are by no means identical, and some of them have quite unique capabilities. Below is a brief description of the various features. Tables 1 and 2 summarize some important information for each satellite.

Beacons

Each satellite has one or more 10-meter beacon frequencies, as

RS-5	29.450	145.830	29.330
RS-6	29.450	—	—
RS-7	29.500	145.840	29.340
RS-8	29.500	—	—

Table 1.

COMMUNICATION PASSBANDS
(MHz)

Satellite Name	Uplink Passband	Downlink Passband
RS-5	145.910-145.950	29.410-29.450
RS-6	145.910-145.950	29.410-29.450
RS-7	145.960-146.000	29.460-29.500
RS-8	145.960-146.000	29.460-29.500

Table 2.

shown in the Table 1. When you hear one of the RS satellites, the frequency of the beacon can be a guide as to which bird it is. The beacon frequencies of RS-5 and RS-7 change when the satellite is in the "robot" mode. See below.

The beacons transmit telemetry information in a coded format. The information is sent in Morse Code at 20-30 words per minute. Each telemetry frame consists of the satellite identifier plus seven pieces of data. A typical telemetry frame might consist of "RS5 K00 D00 O76 G00 U00 S15 W17." As this is being written, the only channel thus far interpreted is the K channel, which indicates the output power of the transponder. When the value for K is 00, as in the example above, this means that the satellite's transponder is presently turned off. A K value other than 00 indicates that the transponder is in operation.

Transponders

At press time, RS-5, 6, 7, and 8 were known to contain transponders for two-way communication. These operate in Mode A, which means you transmit to the satellites on 2 meters between 145.910 and 146.000 (the uplink), and listen for returning signals on 10 meters just below the beacon frequency (the downlink). Table 2 summarizes the transponder uplink and downlink frequencies.

Since a popular class of Soviet amateur license allows only low-power operation on VHF, these latest birds have very sensitive receivers. Therefore, it is recommended that you use no more than 10 Watts effective radiated power (erp) when attempting to communicate through the RS satellites.

Robots

The most unusual feature of the new RS satellites is the "robot," an automatic CW QSO device present on RS-5 and RS-7. When operating, the robot calls CQ on one of the beacon frequencies and then listens for amateurs to respond on a specific 2-meter frequency. If you make the proper response, the robot then sends a short confirmation message containing your callsign, assigning a number to your contact, and thanking you for the QSO.

If I am trying to work the RS-5 robot, for instance, the response expected by the robot is "RS5 DE WB8BTH AR" or "RS5 DE WB8BTH AR K" (it's not yet clear if the final "K" is necessary). Of course, you must substitute your own callsign as well as send the proper satellite identifier. If the robot has copied your complete response correctly, it will confirm the contact by sending "WB8BTH DE RS5 QSO NR XXX OP ROBOT TU FR QSO 73 SK." The XXX is a serial number assigned by the robot to your QSO. Sometimes the robot will "listen" to several callers and then send several confirmation messages in succession.

The uplink frequencies for robot operation are given in Table 1. The best success has been achieved when transmitting slightly (perhaps 4 kHz) below the frequencies in the table. Sometimes the beacon and robot frequencies are interchanged, so be sure to tune around.

Experiments

According to the Soviets, RS-3 and RS-4 are intended for experimental use, explaining why no transponder or robot activity was heard on these satellites during their early life. By the time you read this, these two satellites may have produced some surprises.

Orbital Parameters

The first rough estimates for the orbital periods of the new satellites range from 118.52 minutes for RS-3 to 119.77 minutes for RS-8. The corresponding per orbit longitude increments vary from 29.76 to 30.07 degrees. When the six satellites were first launched, they were quite close together. However, since they are in slightly different orbits, they quickly began to drift away from one another.

Summary

The new RS satellites are very easy to hear. In the mid- to late evening, and again in the late morning hours, the six satellites have been solid copy, even on inexpensive shortwave receivers. A dipole or other simple 10-meter antenna will be perfectly adequate for good reception.

At this writing, the new satellites were only two weeks old, and their orbital parameters were not known with sufficient accuracy to permit the preparation of reference orbit tables, such as those published for OSCARs 8 and 9. More up-to-date information on the RS satellites can be found in ARRL bulletins and on the various AMSAT nets. Thanks to WB1EYI and W9KDR at the ARRL for their assistance in providing information used in this article. —WB8BTH.

DX

AMATEUR RADIO IN PARADISE

Cook Islands certainly has a lot to offer the traveling ham. There are only twenty-five amateurs, and its Prime Minister, Tom Davis ZK1AN, is very active on the air. It is an excellent location for working all types of DX, and when you are operating from there, you are rare DX yourself.

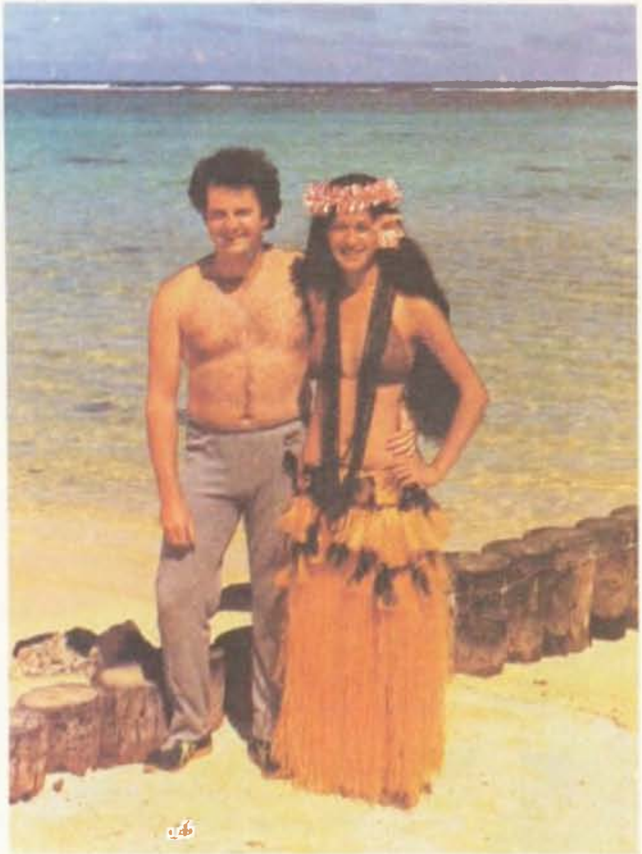
If the Cook Islanders are not already famous for their friendly, hospitable ways, it is only because the world has seen so little of them. Long isolated from major travel routes and today's world of bustling cities and crowded beaches, the islands which make up the self-governed area of Cook Islands are possibly the last unspoiled discoveries in the South Pacific.

The fifteen islands that comprise Cook Islands lie scattered over 751,000 square miles of the Pacific to the northeast of New Zealand. There are two distinct groups, the Northern and the Southern.

In the north lie the islands of Penrhyn, Nassau, Pukapuka, Manihiki, Rakahanga, and Suwarrow. All except Nassau are coral atolls. Amateur radio activity there is sparse, often only from visiting hams sent for research or for United Nations work. At the moment, there are no permanently active hams in the Northern Cooks. I was recently on Manihiki Atoll for two weeks and made seventy HF contacts. Unfortunately, however, Murphy struck in the form of two large lizards which shorted out the rectifier board and the power transformer in my Kenwood 530S transceiver, limiting the number of radio contacts that I could have. (I will be making another trip shortly and hope this time to have a spare rig available.)

The Southern Group consists of two atolls, Palmerston and Manuae, and seven islands. These are Mangaia, Aitutaki, Atiu, Mauke, Mitiaro, Takutea, and the largest island and capital, Rarotonga, the most developed of all of them, although it is only twenty-five square miles in area.

Rarotonga is a fertile island with the breathtaking scenic beauty of white sand beaches and a sparkling clear lagoon. It has spectacular rugged mountain peaks together with a warm tropical climate perpetually tempered by the soft, cool, southeast trade winds. The highlands are mainly covered with tropical evergreen forests while the lowlands and valleys are used for planting.



The author and a Cook Islands friend.

Cook Islands, with a population of eighteen thousand, is virtually bereft of natural resources and is dependent for its livelihood mainly on overseas trade. It imports over fifty percent of its food, all of its raw materials, plant machinery, and oil, the main source of energy in the islands. The main exports are bananas, copra, and canned orange and pineapple juices. It is completely self-governing, with an elected Prime Minister and legislature.

All electricity in the islands is produced from oil imported from Fiji, and, like most other developing countries, Cook Islands is simply reeling under the burden of vastly higher energy costs and increasing food prices.

Amateur radio equipment for use in Cook Islands has a twenty percent customs duty levied upon it. In the case of an amateur bringing his own equipment for his own personal use, no duty is paid as long as the equipment leaves the country with the foreign ham. Local ac voltage is 240 volts, 50 Hz. The license fee is NZ$6.00 per annum and is issued upon presentation of a copy (or the original) of your home station license. A very quick way of obtaining a ZK license is to forward full particulars to Miss Jane Amoa, PO Box 243, Rarotonga, Cook Islands, South Pacific.

Miss Amoa also runs an excellent service for the visiting amateur. This service provides a beach house complete with all the latest radio gear including

antennas for all bands, a housemaid, and car or bike rental, all for a very reasonable cost. In addition, portable generators with multi-voltages, transceivers, and antennas all can be hired by the more adventurous ham who wants to stage his own DXpedition to the outer or Northern Group of islands.

There are no television transmissions in Cook Islands, but there is an FM broadcast station on 103 MHz. Radio Cook Islands broadcasts on shortwave—11760 kHz, and ZK4 and 1ZC on medium wave—630 kHz.

Stuart Kingan ZK1AA handles all of the interisland telephone patching, using modified amateur equipment. Transmissions are on 4038.00 MHz USB from 1800 hours GMT for the Southern Group. Northern Group transmissions are on 12214.00 MHz USB from 2000 hours GMT. His callsign for this network is ZKA2. He is also in charge of the PEACESAT network, transmitting as ZK1XA Rarotonga on satellite frequency 149.220 MHz and receiving on 135.600 MHz from 0200 hours GMT. He uses very modest circularly-polarized antennas with 150 Watts output, which give excellent results. The network is in use daily.

Shortage of equipment and trained personnel to teach local youngsters about amateur radio and electronics is the main reason why so few new licenses are being issued.

If you ever have the chance to visit Cook Islands, I strongly suggest you take out a license and operate, as conditions are excellent to all parts of the world. The local people are friendly and very helpful.

Kia Orana!

CONTESTS

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

QCWA QSO PARTY—PHONE

Starts: 0001 GMT, March 13
Ends: 2400 GMT, March 14

This is the second weekend of the 25th annual QCWA QSO party. Contacts with the same station on more than one band can be scored only once. Contacts made with "captive" stations, such as those operating in local nets, are not valid.

EXCHANGE:

QSO number, operator's name, and QCWA chapter identification (official number or name). Members not affiliated with a chapter should use "AL".

FREQUENCIES:

Any authorized amateur frequency is permissible. The following suggested frequencies have been selected to minimize interference to others: 3900-3930, 7230-7260, 14280-14310, 21350-21380, and 28600-28630. The above frequencies are selected as a starting place. When pileups occur, don't be afraid to go to either side of these frequencies.

SCORING:

Each contact made with another QCWA member will count as a single point. This year's contest has two multipliers. The first is the same as in years past: Each chapter is a multiplier of one. The second is that DX stations are a multiplier of two. DX stations are defined as Europe, Africa, South America, Asia, and Oceania—the same as for WAC of ARRL. Contacts within your own country count only as a chapter multiplier. Final score is then the total QSO points times the sum of the number of chapters and DX stations worked.

AWARDS:

Plaques for the top phone and top CW scorers. Certificates will be given for the 2nd through 5th runners-up in both the phone and CW parties. Standings and scores will be published in the *QCWA News* (summer, 1982, issue).

ENTRIES:

Logs should include the following information: time (GMT), call, QSO numbers, name, chapter number or name, and state or country. It is the responsibility of each contestant to provide a legible log (no carbon copies) and to list all claimed contacts. The total contacts for each page will be recorded at the bottom of each page. The total contacts for the party should be recorded at the top right of the first page of the log. Log sheets will not be returned. Make sure you have correct postage when you mail your logs. Send logs not later than March 31st to: Pine Tree Chapter #134, Glenn Baxter K1MAN, Long Pond Lodge, Belgrade Lakes ME 04918. Separate logs and scores must be submitted for both the CW and phone parties. Work as many QCWA members as possible and apply for any of the special QCWA certificates which you may have qualified for: Worked 50 States, Worked 60 Chapters, Worked 100 Members, and/or Worked 500 Members.

RSGB COMMONWEALTH CONTEST

Starts: 1200 GMT, March 13
Ends: 0900 GMT, March 14

This contest is open only to members of the RSGB resident in the UK, and radio amateurs licensed to operate within the British Commonwealth or British Mandated Territories.

The general rules for RSGB HF contests, published in the January, 1982, issue of *Radio Communication*, will apply. This contest is a single-operator, single-transmitter event. Evidence of simultaneous operation on more than one frequency may result in disqualification.

Also, all contacts must be on CW only. Contacts may be made with any station using a British Commonwealth callsign, except those within the entrant's own call area. UK stations may not work each other for points.

EXCHANGE:

RS(T) plus serial number starting at 001.

FREQUENCIES:

*Winner of QSO Party Certificate Award
#Operated from Skamania/Klickitat county line
Numbers after call letters are: QSOs, multiplier, and total score.

Use all bands, 80 through 10 meters. In accordance with IARU recommendations, contestants are requested to operate within the lower 30 kHz of each band except when contacting Novice stations.

SCORING:

Each completed contact counts 5 points per QSO. In addition, a bonus of 20 points may be claimed for the first, second, and third contacts with each Commonwealth call area. All British Isles prefixes (G, GB, GD, GI, GJ, GM, GU, and GW) count as one call area.

AWARDS:

To the winner, the BERU Senior Rose Bowl; to the runner-up, the BERU Junior Rose Bowl; and to the leading UK station, the Colonel Thomas Rose Bowl. Certificates of merit will be awarded to the first through third placings in home and overseas multi-band or single-band entries, as well as to the leading station in each overseas call area.

ENTRIES:

Separate logs are required for each band. Each band log should be separately totalled and should include, at the end, a check list of call areas worked on the band. Logs must include GMT time, callsign of station worked, exchanges, and points claimed. Separate band totals should be added together and total claimed score entered on the cover sheet. It is important that logs are carefully checked for duplicate contacts. Unmarked duplicate contacts for which points have been claimed will be heavily penalized and logs containing in excess of five will be disqualified.

Entries may be single- or multi-band. Single-band entries should show contacts on one band only; details of contacts made on other bands should be enclosed separately for checking purposes. Multi-band entries will not be eligible for single-band awards. Each entry will consist of the separate band logs together with a cover sheet, summary, and declaration that the rules and spirit of the contest were observed. Entries should be addressed to: D. J. Andrews G3MXJ, 18 Downsview Crescent, Uckfield, East Sussex TN22 1UB, England. All entries must be received no later than May 17th.

VIRGINIA STATE QSO PARTY

Starts: 1800Z, March 13
Ends: 0200Z, March 15

Sponsored by the Sterling Park Amateur Radio Club. This year there are three categories of participation: 1) fixed or portable single transmitter, 2) fixed or portable multi-transmitter, and 3) mobile.

EXCHANGE:

QSO number and QTH (county for VA stations; state, province, or country for others).

FREQUENCIES:

Phone—3930, 7230, 21375, 28575; CW—60 kHz from low end, plus Novice bands.

SCORING:

Count one point per QSO. A station may be worked once on each band/mode. In addition, Virginia mobiles may also work the same station from each county visited. Virginia stations multiply QSO points times total of states, provinces, countries, and VA counties worked to get final score. All others multiply QSO points times numbers of VA counties worked to get final score. Virginia counties are determined by the USA-CA counties list.

AWARDS:

A plaque will be awarded to the highest Virginia score. Certificates go to the highest score in each state, province, country, and VA county.

ENTRIES

Mail logs and summary sheets no later than April 15, 1982, to A. Ray Massie K3RZR, Rt. 1 Box 115E, Dunnsville VA 22454. For a copy of the results, please include an SASE.

YL ISSB QSO PARTY—CW

Starts: 0001 GMT, March 20
Ends: 2359 GMT, March 21

Two six-hour rest periods are required. Operating categories include: single operator, DX/WK teams, and YL/OM teams. All bands will be used and the same station may be contacted on different bands for contact points but not as country multipliers. Two meters may be used, but contacts must be direct and not through repeaters.

EXCHANGE:

Name, RST, SSBer number, country, state, and partner's call. If no partner, leave blank. If non-member, send "no number."

SCORING:

Score eight points for each member contacted on any continent. Non-member contacts count *one* point. Only member station contacts count for multipliers. Multipliers are each state, country, and province, as well as each team contacted (only once for each team). When DX/WK partners contact each other, it counts as a double multiplier. Final score is sum of QSO points times the total multiplier.

ENTRIES:

Logs must show date/time (GMT), RST, SSBer number, partner's call, mode of operation, band, and period of rest time. Summary sheets show number of states, Canadian provinces, countries, YL/OM teams, DX/WK teams, and partner contacts. Send logs, summary sheets, and completed YL ISSB QSO Party applications to Minnie Connolly

WISCONSIN ASSOCIATION OF REPEATERS
NEWSLETTER

NEWSLETTER OF THE MONTH

Some clubs have broad membership with diverse interests, while others focus much more closely on a single aspect of amateur radio. Similarly, a newsletter should contain information relating to the club's specialty. A general-interest club shouldn't fill its newsletter with DX info, while a DX-club newsletter would lose readership rapidly if it concentrated on 75-meter rag chewing.

This month's winner, the Wisconsin Association of Repeaters newsletter, sticks to its specialty and covers it well. WAR is the frequency coordinating body for repeaters in Wisconsin and, frequency coordination being the touchy matter it is, keeping the members (who are primarily repeater owners) informed is very important. The December issue is four letter-size pages long and includes an editorial regarding newsletter policies and an explanation of the new size of the newsletter (it used to be printed in half-page size). WAR's chairman writes concerning the new regulatory mood in Washington and the frequency coordinator describes in a "bedtime story" a recent problem concerning coordination in the state and uses it to point out the repeater owner's responsibility in the coordination process. The bulletin finishes off with minutes of the last (quarterly) meeting—particularly important for a club which draws its membership from across a large state.

The newsletter is printed by offset on colored paper with attractive graphics. Perhaps its nicest feature is the inclusion of an up-to-date listing of all coordinated repeaters in the state, arranged by geographical region. One portion of the list is a map of Wisconsin showing the regional breakdowns, so it is easy to determine in which region a repeater belongs. The list is printed on both sides of a separate letter-size sheet, so the newsletter needn't be defaced to save the list.

A newsletter editor needs to keep in mind the audience he is trying to reach; if he gives his specialized audience the specialized information that they joined together to learn, they will be happy both with the newsletter and with the club.

KA0ALX, Star Rt. #1, Crocker MO 65452. Anyone needing blank forms or further information should send an SASE to the same address.

BARTG SPRING RTTY CONTEST

Starts: 0200 GMT, March 20
Ends: 0200 GMT, March 22

The total contest period is 48 hours, but not more than 30 hours of operation is permitted. Time spent as listening counts as operating time. The 18 hours of non-operating time can be taken at any time during the contest, but off periods may not be less than 3 hours at a time. Times on the air must be summarized on the summary sheet.

There are separate categories for single-operator, multi-operator, and shortwave listener stations. Use all amateur bands from 80 through 10 meters. Stations may not be contacted more than once any one band.

EXCHANGE:

The message exchange consists of:

1) Time in GMT; this must consist of a full four-figure group and the use of the expression "same" or "same as yours" will not be acceptable.

2) RST and message number; the message must consist of a three-figure group starting with 001 for the first contact made.

SCORING:

All 2-way RTTY contacts with other stations within one's own country earn two points; contacts outside your country earn ten points. All stations can claim a bonus of 200 points for each country worked, including their own. Note that any one country may be counted again if worked on a different band, but the continents are counted once only. The ARRL country list is used and, in addition, each W/K, VE/VO, and VK call area will be counted as a separate country. Final score is (sum of QSO points times the total number of countries worked) added to (the number of countries times 200 bonus points each times the number of continents). Note: Proof of contact will be required in cases where the station worked does not appear in any other contest log received or the station worked does not submit a check log.

AWARDS:

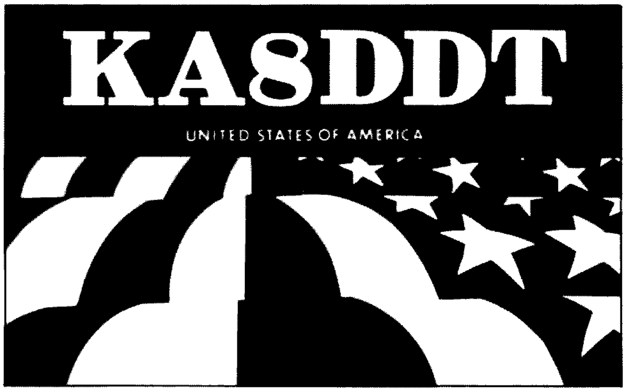
Certificates will be awarded to the leading stations in each of the three classes, the top station in each continent, and to the top station in each W/K, VE/VO, and VK area.

If a contestant manages to contact 25 or more different countries on 2-way RTTY during the contest, a claim may be made for the Quarter Century Award (QCA) issued by BARTG and for which a fee of $3.00 (USA) or 15 IRCs is required. Make your claim at the same time you send your log. Holders of existing QCA awards should indicate and list any new countries to be added to their existing records. Make your claims at the same time that you send in your log. However, due to the high volume of work, it will not be possible to prepare and dispatch any new awards or update any existing awards until the final results of the contest have been evaluated and published.

Additionally, if any contestant manages to make contacts on 2-way RTTY with each of the six continents and the BARTG Contest Manager has received either a contest or check log from each of the six stations concerned, a claim may be made for the WAC Award issued by the American *RTTY Journal*. The necessary information will be sent to the *Journal*, which will issue the WAC Award free of charge.

ENTRIES:

Use a separate sheet for each band and indicate all times on the air. Logs should contain: date/time in GMT, callsign of station worked, RST and message number sent, time RST and number received, and points claimed. Logs received from shortwave listeners *must* contain the callsign of the station heard and the report sent by that station to the station he is working. Incomplete loggings are not eligible for scoring. The summary sheet should show the full scoring, the time *on* the air, and, in the case of multi-operator stations, the names and callsigns of all operators involved with the operation of the station. All logs must be received by May 31st in order to qualify. Summary and log sheets are available from the Contest Manager at the address shown below. The judges' decision will be final and no correspondence can be entered into with respect to incorrect or late entries. All logs submitted will remain the property of the British Amateur Radio Teleprinter Group. Send entries to: Ted Double G8CDW, 89 Linden Gardens, Enfield, Middlesex EN1 4DX, England.



QSL OF THE MONTH: KA8DDT

Does the design on David Ashenfelter KA8DDT's card look familiar? It's based on graphics used by ABC News during the 1980 presidential election.

If you would like to enter our contest, put your QSL card *in an envelope* and mail it, along with your choice of a book from *73*'s Radio Bookshop, to *73 Magazine*, Pine Street, Peterborough NH 03458, Attention: QSL of the Month. Entries which do not use an envelope (the Postal Service does *occasionally* damage cards) and do not specify a book will not be considered.

SPRING VHF QSO PARTY

Starts: 1600 local time, March 27
Ends: 2400 local time, March 28

Sponsored by the Ramapo Mountain ARC. The contest rules are considerably different from the last two contests.

Classes of entry include single- and multi-transmitter. A station of the single-transmitter class may operate using several different transmitters but may not emit more than one signal at any given time. A station of the multi-transmitter class may operate simultaneously with a single emission on several different bands. The number of operators, loggers, etc., does not affect the class of the station entry.

A section is defined as a geographical area one degree in longitude by one degree in latitude, identified by a 4- or 5-digit number indicating the next lowest degree of longitude and latitude. Example: RMARC club station WA2SNA, located in Oakland NJ at 74° 15' west and 41° 3' north, would use a section designator of 7441.

Each QSO has a point of value based on the distance between stations as determined by the larger of the differences between the section designators' latitude or longitude plus 1, with a maximum of 10 QSO points. Example: WA2SNA in 7441 works W3XX in 7638. The difference between 74 and 76 is 2. The difference between 41 and 38 is 3. Three is the larger difference, so adding 1 to it would result in 4 QSO points.

The section multiplier is the total number of different sections worked per band. The following band multipliers are used to determine the final score per band: 50 MHz = ×1, 144 MHz = ×2, 220 MHz = ×4, 432 MHz = ×8, 1296 MHz = ×16, and 2304+ MHz = ×32. The score per band is equal to the total of QSO point values per band times the section multiplier times the band multiplier. The total score is the total of individual band scores. Each two-way QSO must include an exchange of station callsign, section designator, and class of entry (single- or multi-transmitter).

Prepare a separate log sheet for each band. Heading information must include your station callsign, section designator, and class of entry. Each individual QSO entry must include date/time (GMT), callsign, section designator, and entry class of the station worked, and the QSO point value. Per band summary information must include the total of QSO point values

and the total of different sections worked.

Prepare one entry sheet, indicating for each band: band, QSO point total, number of sections, band multiplier, and band score. Also include the total of all band scores. This sheet must also include your station callsign, your section designator, ARRL section and division, and mailing address, and *must be signed* by the licensee or trustee of the call used.

An SASE to the RMARC will obtain log and entry forms. All who submit the required data will receive a copy of their newsletter with results. Award certificates will be issued to the highest scoring stations on each band as well as on a total basis in each ARRL section, division, and overall. Mail forms no later than May 1st to: Ramapo Mountain ARC, PO Box 364, Oakland NJ 07436.

CW & RTTY WORLD CHAMPIONSHIPS

CW Event: 0000 to 2400 GMT, April 3

Phone Event: 0000 to 2400 GMT, April 4

Sponsored jointly by *73 Magazine* and the *RTTY Journal*. Use all bands, 10 through 80 meters, on the specified mode. Cross-mode contacts do not count. The same station may be worked *once* per mode.

Operator classes are: a) single operator, single transmitter, non-computerized; b) single operator, single transmitter, computerized; c) multi-operator, single transmitter, non-computerized; and d) multi-operator, single transmitter, computerized. Single operator stations may work 18 hours maximum per mode, while multi-operator stations may operate the entire 24-hour period. Off times are no less than 30 minutes each and must be noted in logs. To be eligible for the computerized class, your station must be interfaced with a microprocessor-controlled RTTY and/or CW operating system such as the TRS-80, Heath/Zenith, Apple, PET, OSI, Hal, etc. Utilizing a memory keyer for CW does not constitute a computerized station.

Entry categories are: a) CW only, b) RTTY only, and c) CW and RTTY both.

EXCHANGE:

Stations within the 48 contiguous United States and Canada must send RST and state, province, or territory. All others will send RST and a consecutive contact number. If your station is computerized, add the letter "C" to the end of your exchange.

SCORING:

Count 1 QSO point for each valid contact. An additional *bonus* point is earned if the station worked is computerized and sent a "C" at the end of his exchange. Count 1 multiplier point for each of the 48 contiguous United States and each Canadian province/territory and DX country (outside the contiguous US and Canada). The total claimed score is the total QSO points times the total multiplier points.

AWARDS:

Contest awards will be issued in each entry category and operator class in each of the US call districts and Canadian provinces and territories, as well as in each DX country represented. Other awards may be issued at the discretion of the awards committee. A minimum of 5 hours and 50 QSOs must be worked on a mode to be eligible for awards.

ENTRIES:

Entries must include a *separate* log for each event entered, a dupe sheet, a summary sheet, a multiplier check list, and a list of equipment used for each mode of operation. Contestants are asked to send an SASE to the contest address for official forms!

Omission of the required entry forms, operating in excess of legal power, manipulating scores or times to achieve a score advantage, or failure to omit duplicate contacts which would reduce the overall score more than 2% are all grounds for immediate disqualification.

Entries must be postmarked *no later than* May 10th and sent to: CW and RTTY Championships, c/o The *RTTY Journal*, PO Box RY, Cardiff CA 92007.

Hara Arena and Exhibition Center — Dayton, Ohio

Meet your amateur radio friends from all over the world at the internationally famous Dayton HAMVENTION. Seating will be limited for Grand Banquet and Entertainment on Saturday evening so please make reservations early. Banquet speaker is Roy Neal, K6DUE, NBC News.

If you have registered within the last 3 years you will receive a brochure in late February. If not write Box 44, Dayton, OH 45401.

Nominations are requested for Radio Amateur of the Year and Special Achievement Awards. Nomination forms are available from Awards Chairman, Box 44, Dayton, OH 45401.

For special motel rates and reservations write to Hamvention Housing, 1406 Third National Bldg., Dayton, OH 45402. **NO RESERVATIONS WILL BE ACCEPTED BY TELEPHONE.**

All other inquiries write Box 44, Dayton, OH 45401 or phone (513) 849-1720.

Rates for ALL 3 Days: Admission: $7 in advance, $8 at door.
Banquet: $14 in advance, $16 at door.
Flea Market Space: $15 in advance.

Make checks payable to Dayton HAMVENTION, Box 333, Dayton, OH 45405.
Bring your family and enjoy a great weekend in Dayton.
Sponsored by the Dayton Amateur Radio Association, Inc.

AWARDS

Bill Gosney KE7C
Micro-80, Inc.
2665 North Busby Road
Oak Harbor WA 98277

TEN-METER FM AWARDS

- Sponsored by the North Whidbey Island Repeater Association (NWIRA).
- All contacts, to be valid, must have been made on/after January 1, 1981.
- Crossmode contacts do not count. Contacts must be 2-way ten-meter FM.
- Special endorsements can be made for all-mobile, all-simplex, and single-frequency accomplishments and contacts made within a single day, week, month, or year.
- Note: Members of the NWIRA monitor 29.600 MHz, as well as the area repeater on 29.640 MHz (an 1800-Hz tone or whistle is required to access).
- *Do not* send QSL cards! Forward your list of contacts showing the date, time, and frequency of each QSO and provide a brief station description, along with the fee of $4.00 for each award, to Ten-Meter FM Awards Program, 2665 North Busby Road, Oak Harbor WA 98277.

Worked All Districts Award

To qualify, applicants must work one ten-meter FM station in each of the ten US call districts.

Worked All States Award

Applicants must work a *minimum* of fifty US states on ten-meter FM.

Centurion Award

This award requires the applicant to work a *minimum* of 100 stations on ten-meter FM.

DX Decade Award

Applicants must work a *minimum* of ten DX stations outside the fifty US states and Canada on ten-meter FM.

North American Award

To qualify, applicants must work all ten US call districts, a *minimum* of six Canadian provinces and/or territories, and at least four DX countries within the North American continent (other than the US and Canada) on ten-meter FM.

OPERATING ACHIEVEMENT AWARDS FROM *A5 MAGAZINE*

Fast-Scan ATV Award

"Getting the amateur television station operating is an award in itself!" This award certificate recognizes the "first" amateur television two-way contact. Endorsements for DX mileage and color ATV are available. Contacts via ATV repeaters are allowed. Award inscriptions are made around the border of the A5 block. Black/white, 8" × 10".

Master Scanner A5 SSTV Award

This award certificate recognizes the serious SSTVer. Entry level is 100 two-way SSTV contacts. Endorsements for 500, 1000, 1500, 2000, etc., are available. Special endorsement for color SSTV available with verified print copy. A must for every SSTVer! Gold, 8" × 10".

Specialized Communications Achievement Award

This award recognizes accomplishments in ATV, MSTV, NBTV, SSTV, fax, RTTY, EME, microwaves, and satellites. Entry levels are contacts over 100 miles on ATV. Special-event ATV projects, 25 DX country contacts on SSTV, reception of HF MSTV or fax signals via amateurs, microwave DX, 10 DX foreign countries via EME, 10 two-way contacts on an amateur satellite, and 25 DX countries on RTTY are required, with special endorsements available for additional contacts. Certificates are numbered as received. Gold, 8" × 10", suitable for framing.

Worked All States SSTV

Work all 50 states (including Hawaii and Alaska) with exchange of callsign and signal report in video. A special WAS map is available to color in the states as you get them. This is an ongoing award not limited to the annual contest. Special endorsements available for multiband WAS.

Worked All States RTTY

Work all 50 states (including Hawaii and Alaska) with log copy verification. This is an ongoing award not limited to the annual contest. Special endorsements available for multiband WAS.

"Good Image" Award

Awarded at the Dayton Hamvention each year, the Good Image Award is presented to the individual or group of individuals who contributed to the advancement of the A5 code of communication by technical achievement or public awareness. Top-of-the-line award!

All *A5 Magazine* awards require subscription label information date codes. Enclose $1.00 for the cost of the award certificate and 50¢ postage for return mailing (envelope is provided). Allow 2-3 weeks for verification and mailing. Send all requests to Awards Manager, *A5 Magazine*, PO Box H, Lowden IA 52255-0408. Winners of awards will be published on a regular basis in *A5 Magazine*.

CENTRAL STATES VHF SOCIETY OPERATING AWARDS

At the 1981 Central States VHF Conference in Sioux Falls, South Dakota, in August, the Central States VHF Society formally announced its new operating awards program with three colorful awards for VHF/UHF/SHF bands.

Each award was designed to stimulate activity on the bands above 144 MHz. The differences in the awards as well as the variety of endorsements available provide challenging but achievable goals regardless of the station's geographic location or capabilities.

The awards are open to all amateurs—not just CSVHF Society members. To receive rules and application sheets, send a legal-size SASE (with two stamps) to Bob Taylor WB5LBT,

10715 Waverland, Baton Rouge LA 70815.

General Rules—All Awards

● The awards described below are available to all amateurs worldwide who submit details of the required contacts (on the separate award Application Detail Sheet) and have the accuracy of the application certified by a local member in good standing of the CSVHF Society. In addition to the basic awards, certain optional endorsements are available as described below and on the Application Cover Sheet.

● For all awards, direct two-way communication must be established on amateur radio bands of 144 MHz and above. Minimum contact requirements are the exchange of callsigns, signal reports (or other mutually understood information), and receipt of acknowledgement that both stations have received this information. All contacts for each award must be on the same band.

● Contacts must be made from the same location or from other location(s) licensed to the applicant, no two of which are more than 50 miles apart.

● Contacts for the VUCC and WHG awards may be made over any period of years, with no starting date, but *numbered* certificates will only be issued to those who have made all the required contacts after August 1, 1981. 1K Coverage Award contacts must be made during any two consecutive months after August 1, 1981.

● Contacts made through "repeater" devices or any other power relay method do not count toward any of the awards. In addition, no crossband contacts are permitted.

● False statements on the Application Cover Sheet or on the Detail Sheet(s) shall result in immediate disqualification for any of the awards.

● Remember, you do not have to be a member of the CSVHF Society to apply for an award. However, if you wish to join, send the $5.00 membership dues to: Ted Mathewson W4FJ, CSVHF Society Secretary, 1525 Sunset Lane, Richmond VA 23221. Please do not send dues with awards applications.

VUCC

The VUCC (VHF/UHF Century Club) award simply requires contacts with 100 different amateur stations. Optional endorsements for working additional stations in increments of 25 (e.g., 125, 150, 175, etc.) or for making all the contacts during a single calendar year (Jan. 1 through Dec. 31) are available *only* if all the contacts were made on the same mode of propagation (sporadic E skip, EME, meteor scatter, or aurora).

1KCA

The 1K Coverage Award requires contacts of sufficient number and distance such that the sum of the QSO points for all the contacts during *each* of any two consecutive calendar months is equal to or greater than 1000. The QSO points for any given contact are the band points multiplied by the distance points. The band points are determined as follows: 144 = 2, 220 = 5, 432 = 4, 1295 = 5, 2300 = 10, 3300 = 15, 5650 = 25, and 10 GHz and up = 50. The distance points are simply the number of 1° × 1° "grids" (see definition under WHG Award) you are away from the other station's 1° × 1° grid. For example, if the station is in the next grid over from yours, the distance points for the contact are 1; if it is two grids over, the distance points are 2, etc. Contacts in your own grid have a distance point value of 1. For stations which are not in a grid directly north, south, east, or west of yours (i.e., off at an angle), the distance points have to be calculated. In such cases, the distance points are equal to the square root of the sum of the latitude difference squared and the longitude distance squared, where the differences in latitude and longitude are measured in numbers of whole 1° × 1° grids. The resulting distance points are to be rounded off to the nearest tenth. Only one contact with a given station per GMT day counts toward this award, and EME contacts do not count. There are no additional endorsements available for this award.

WHG

The WHG (Worked Hundred Grids) award requires contacts with stations in 100 different 1° × 1° geographic "grids." The 1° × 1° grids are defined as the area bounded by integral values of latitude and longitude. For example, a station whose longitude is 112° 32' 15" west and latitude is 37° 25' 16" north would be in the grid 112W37N. All stations are urged to include their latitude and longitude and/or equivalent recognized QTH locator code on their station cards to assist others in determining their grid. If you have to determine the other station's grid yourself, it can be easily done by looking up the town location in any good road atlas and the locating the position on a larger map which shows the 1° lines of latitude and longitude. Two such maps are:

1. "Map 2-A," which comes in two halves (54" × 80" assembled) and is available for $3.00 postpaid from: Branch of Distribution, U.S. Geological Survey, Federal Center, Denver CO 80225. Shown are counties, county seats, capitals, and cities larger than 500,000.

2. Rand McNally's "Contemporary United States," which measures 36" × 54" and is available through bookstores for $2.95. The map does not show counties but does include major highways, a number of cities and towns, and 3° more latitude in Canada than the USGS map.

Optional endorsements are available for working additional 1° × 1° grids in increments of 25 (e.g., 125, 150, 175, etc.) or for working all the different grids in a single calendar year.

FUN!

John Edwards KI2U

Glendale NY 11385

HOW HAMS VIEW THEMSELVES II

Here we go again. One year and two postal increases later, it's time once more for the famous Fun! poll.

For those who missed last year's event, the Fun! poll is not a scientific survey. What it represents, though, are the gut feelings of amateurs as they answer questions ranging from their personal lifestyles to how they view emerging trends in our hobby. Last year we discovered, for instance, that 12 percent of our respondents used a "cheat book" to upgrade, 54 percent felt that ham radio interfered with their personal relationships, and 61 percent would give up the hobby for a million dollars.

This time around we're keeping many of the old questions and adding some new ones. I hope that you'll take the time to fill out the response sheet and mail it to *the address at the top of this column*.

Last year, some club officers wrote in to say that they made the poll a meeting activity. Photocopy ballots were passed out and members were encouraged to voice their opinions on the various topics. I think that's a great idea. Anything that can get hams thinking and talking can't be all bad. Just be sure to mail in those ballots

ELEMENT 1—BACKGROUND

1) Sex:

A) Male
B) Female

2) Age:
A) 15 or below
B) 16-21
C) 22-39
D) 40-59
E) 60 and above

3) License class:
A) Novice

B) 1-5 years
C) 6-10 years
D) 11-20 years
E) 21 years and up

5) Do you have a new (post-March '78) call?
A) Yes
B) No

6) How many hours a week do you devote to amateur radio?
A) 0-1 hour
B) 2-5 hours
C) 6-10 hours
D) 11-20 hours
E) 21 hours or more

7) Which HF band do you most use?
A) 80-75 meters
B) 40 meters
C) 20 meters
D) 15 and/or 10 meters
E) Don't operate HF

8) Which VHF-UHF band do you most use?
A) 6 meters
B) 2 meters
C) 220 MHz
D) 420 MHz and/or up
E) Don't operate VHF-UHF

9) Which mode do you most use?
A) SSB
B) CW
C) FM
D) RTTY
E) Other

10) How much money have you spent on amateur radio within the past year? (Include QSL expenses, magazine subscriptions, club dues, and other incidental expenditures.)
A) 0-$250
B) $251-$500
C) $501-$1,000
D) $1,001-$2,500
E) $2,501 and up

ELEMENT 2—SOCIAL CHARACTISTICS

11) Has amateur radio influenced your career choice?
A) Greatly
B) Somewhat
C) Not at all

12) Do you answer QSLs with no return postage?
A) Yes
B) No

13) Politically, how would you define yourself?
A) Conservative
B) Middle-of-road
C) Liberal

14) Do you think amateur radio will exist 20 years from now?
A) Yes
B) No

15) Have you ever had a fight with a family member over amateur radio?
A) Yes
B) No

16) Do you have any relatives who are hams?
A) Yes
B) No

17) Are most of your friends (more than half) hams?
A) Yes
B) No

18) Did you ever use a "cheat book" (not counting the ARRL License Manual) to upgrade your license?
A) Yes
B) No

19) If someone offered you five million dollars, tax free, on the condition you give up amateur radio forever, would you?
A) Yes
B) No

20) Do you belong to a local ham radio club?
A) Yes
B) No

21) Have you ever attended a ham flea market?
A) Yes
B) No

22) Have you ever attended the Dayton Hamvention?
A) Yes
B) No

23) Would you pay five dollars to join the ARRL if they offered no magazine, QSL services, awards, or technical and instructional help?
A) Yes
B) No

24) Would you like to see another national organization compete with the ARRL?
A) Yes
B) No

ELEMENT 3—OPERATING HABITS

25) Would you favor a licensing system that had only two classes: Novice and General or Communicator and General?
A) Yes
B) No

26) Would you like to see the FCC turn over amateur testing responsibility to clubs?
A) Yes
B) No

27) Do you think religious and politically-oriented nets have a place in ham radio?
A) Yes
B) No

28) Should contests be outlawed?
A) Yes
B) No

29) Do you think the FCC should assign exclusive frequencies and times to nets?
A) Yes
B) No

30) Do you think the FCC should assign exclusive frequencies to repeaters?
A) Yes
B) No

31) Should there be a no-code, VHF and above, "digital-class" license? This license would require a heavy theory test and carry no phone or CW privileges (except perhaps for ID purposes).
A) Yes
B) No

32) Should there be a no-code, 220 MHz, "communicator-class" license? This license would require a moderately difficult theory test and carry only F3 privileges at a maximum of 50 Watts.
A) Yes
B) No

33) Do you own a microcomputer?
A) Yes
B) No

34) What sort of CW sending device do you most often use?
A) Straight key
B) Keyer
C) Bug
D) Keyboard
E) Never operate CW

35) If required, could you solidly copy CW at the speed at which you were licensed?
A) Yes
B) No

36) Have you ever purposely operated in an amateur subband you weren't licensed to use?
A) Yes
B) No

37) Do you think the FCC affects amateur radio in a positive manner?
A) Yes
B) No

38) Do you ever speak to foreign, non-English-speaking hams in their own language?
A) Always
B) Sometimes
C) I attempt it
D) Rarely
E) Never

39) Do you feel yourself competent to replace the finals in a tube-type rig?
A) Yes
B) No

40) Do you feel yourself competent to replace the finals in a transistor-type rig?
A) Yes
B) No

41) Have you ever built an electronic project from a kit?
A) Yes
B) No

42) Have you ever "home-brewed" an electronic project from a book or magazine?
A) Yes
B) No

43) Have you ever designed your own electronic project?
A) Yes
B) No

44) What do you think of contesting?
A) Great
B) Good
C) Okay
D) Don't like it
E) Despise it

45) What do you think of DXing?
A) Great
B) Good
C) Okay
D) Don't like it
E) Despise it

46) What do you think of repeaters?
A) Great
B) Good
C) Okay
D) Don't like them
E) Despise them

47) What do you think of traffic handling?
A) Great
B) Good
C) Okay
D) Don't like it
E) Despise it

48) Do you plan to use Phase III OSCAR within a year of its launch?
A) Yes
B) No

49) Do you plan to use the new 10.1 MHz band within one year of its opening?
A) Yes
B) No

50) Do you believe amateurs should have the right to build, use, and sell equipment intended for the reception of subscription television?
A) Yes
B) No

REVIEW

THE YAESU FT-680R TRANSCEIVER

The Yaesu FT-680R is a compact, six-meter, multi-mode transceiver designed for both mobile and fixed station use. It is part of a rather complete line of nearly identical VHF/UHF transceivers which includes the FT-480R two-meter and the FT-780R 430-MHz multi-mode rigs.

The FT-680R is fully synthesized, with a four-bit NMOS microprocessor-controlled operating frequency, scanning, priority channel selection, and the various memory functions. Frequency coverage is from 50 to 53.99999 MHz, in steps of 10 Hz, 100 Hz, and 1 kHz in SSB (CW and AM modes) and 1-kHz, 20-kHz, and 100-kHz steps in the FM mode. These steps correspond to one click on the main tuning knob, or one press of the up or down buttons on the microphone.

Of the sixteen controls on the front panel, eleven are associated with frequency selection. The other five are volume and squelch controls, high/low power switch, and a noise-blanker on/off switch. The microphone jack is an eight-pin affair identical to that found on many Icom rigs and provides for microphone-mounted up/down scanning switches, a "Call" button for tone-burst operation, and a microphone lock switch, in addition to the obligatory PTT, signal, and ground lines.

Underneath the front panel on the right-hand side are three switches: SAT, which allows the operating frequency to be changed while transmitting, a repeater offset selector, and a busy/clear scanning selector. A miniature connector is located near the back of the bottom panel, allowing tone burst on six meters. The unit's speaker is also on the bottom panel.

The rear panel is mostly heat sink, but squeezed into the corners are jacks for antenna, power, and CW key. The entire unit measures approximately 2½" high, 7¼" wide, and 9½" deep. A hefty mobile bracket is included, as is a wire bail for home use. The bail is necessary because the speaker housing prohibits the rig from sitting flat on a table without it.

Other Features

Upon first unpacking the FT-680R, I decided that the front panel was the most confusing I had ever encountered. This is no small distinction, considering the needlessly complex panels on some of the competition! However, my opinion was modified considerably after reading the instruction manual. In retrospect, the 680 offers a thoughtful layout. What need work are some of the labels over the switches. For example, use of the switch marked DIL is not exactly obvious. A glance at the manual explains everything. The switch "... transfers frequency control from the memory channels to the main tuning knob." That makes perfect sense, but please don't ask me what it has to do with DIL! Once you understand some of the confusing labels, the front panel is a lot friendlier.

There are four memories available as well as a priority channel. These function in the generally accepted manner. An interesting and extremely useful twist is the clever programming of the up/down switches on the microphone. At first, they appear to operate just like the mike switches on countless other rigs, but if you hold down one of the switches for more than half a second, the automatic scanner is activated. Even if you release the switch, the unit will continue to scan up or down the band. To stop, simply press either the up or down buttons or the PTT switch. Surprisingly, pushing the PTT switch during scanning will not result in a transmission. The next time you press it though, it will behave normally and you'll be on the air. Nice touch!

The controls on the underside of the transceiver are inconvenient and their labels impossible to read without turning the rig over. Yaesu's engineers correctly assumed that most users would rarely need access to these controls, but they failed to consider how easy it is for an operator unknowingly to change the position of the switches while moving the rig. Hopefully, Yaesu will not mount switches here on future rigs.

Particularly useful to the six-meter DXer is the inclusion of semi-break-in operation on the CW mode. Also included is an 800-Hz sidetone. Missing is an amplifier-keying jack. With 4CX250 amplifiers so easy to home-brew for this band, such a jack is sorely missed. Fortunately, adding one should prove to be easy for anyone on familiar terms with a soldering iron.

The Yaesu FT-680R six-meter transceiver. (Photo by KA1LR)

On the Air

The FT-680R spent several weeks accumulating dust on the shelf after its arrival because I couldn't find the time to install a proper six-meter yagi. One Friday evening as my wife and I settled in to view our favorite program on Channel 2, we found it had been pre-empted. The Boston station we had planned to watch faded in and out of the hash, and then for a few minutes a Florida news broadcast captured the set completely! Without so much as a word, Alyson went to the ham shack, got the FT-680R, and dropped it at my feet. We found a spare 12-volt supply and then hooked up the rig to a Radio Shack TV antenna on the roof. The swr was about 3:1, but the rig put out almost full power and didn't make any funny noises, so I started tuning up the band. Among other things, we heard a Georgia station calling CQ, and I gave him a quick call. Wonder of wonders, he came back with a 59 report! Over the weekend, I worked 21 states in the south and midwest, using 10 Watts PEP and a TV antenna fed with 75-Ohm coax. Bob Cooper in the Turks and Caicos came in 59 + 20 Saturday morning, but I apparently couldn't be heard over the pileup of kilowatts and stacked arrays. I did manage to make several contacts elsewhere using the low-power position (one Watt PEP), but signal strength reports at this power level were not uplifting.

When the band finally went dead and I reconnected the TV, it occurred to me that I had forgotten about the lossy 300-Ohm to 75-Ohm transformer installed at the antenna. Close examination revealed it to be undamaged, but I've always wondered how much power I lost in the darn thing!

All things considered, the 680's performance is outstanding. Receiver sensitivity is more than adequate for all but the most demanding weak-signal work. After a couple of hours with most multi-mode rigs, one usually begins thumbing the catalogs in search of a suitable preamp, but no one who used the 680 ever felt the urge. Receiver audio quality was very good—better than that found on other Yaesu transceivers. Transmit audio reports were excellent, and I'm just as glad the 680 doesn't include a speech processor! The Monadnock region of New Hampshire is not exactly bursting with FM six-meter activity, so about all I can say about the FM section is that it works.

The instruction manual is very complete. Several other well-known manufacturers would do well to offer the sincerest form of flattery—imitation. As well as the usual specifications and operating instructions, the FT-680R owner is furnished with alignment and service instructions, a parts list, a theory of

operation section, and three poster-sized schematics. An amateur radio operator deserves nothing less.

A rather complete line of optional accessories is offered for the 680. For those of us too lazy to build our own, there is the FP-80 dc power supply. The AD-1 antenna coupler permits a single mobile antenna (the RSL-50) to be used with both six- and two-meter rigs at the same time. One less hole in the old crate. Home-station operators will appreciate the choice of stand microphones, including one with scanning push-buttons in the base. Finally, for owners of the 680 and one of its twins, there is the SC-1 station console which makes the rigs into a single compact package and includes a power supply, digital clock, 16-button DTMF pad, and some convenient switching.

Conclusion

Six meters remains one of our interesting amateur bands. Propagation is often unpredictable and wild, rewarding the alert operator with dizzying tours of the country. On occasion, it is rather tame, behaving like a mischievous 10 meters, offering long, solid rag-chews before sweeping your friend off the S-meter. As solar activity provides fewer opportunities to sample the thrills of six-meter DX, the FM position on the mode switch will offer a bastion of tranquility and camaraderie, free from the crowding and circus-like atmosphere that prevails on other, more populous FM bands. Six meters offers some of the very best of the HF and VHF worlds, and the FT-680R provides an excellent means to sample the action. In features, price, and performance, it stands with the best. Yaesu has a winner!

THE CURTIS K5 KEYER

The Curtis keyer IC has been used in countless keyer models offered by a wide range of manufacturers, and with good reason. The chip offers almost every feature a radio operator could require in a non-memory keyer, and very few additional components are needed to produce a complete unit. But while everyone was building keyers around the chip, almost all neglected its most obvious use. Since the component count is so small, why not produce a tiny keyer that could go anywhere, anytime? Well, that's exactly what Curtis did!

The K5 keyer measures only 1-1/2" square by 3-1/16" deep. A tiny glass-epoxy circuit board is securely screwed to a U-shaped piece of .062" heavy aluminum. This assembly slides into a rectangular case, also made of .062" aluminum, and is held in place by friction fit.

On the rear panel are a phono jack for transmitter keying, a submini phone jack for power, and a submini phone jack for sidetone output. Four eight-inch-long lugged wires exit through a plastic grommet. These are for connection to keyer paddle and straight key.

Correctly, the Curtis engineers judged that the only control that most users would need immediate access to is the combination speed control and on/off switch. This is mounted on the otherwise bare front panel. By mounting seldom-used controls inside the box, enough space was saved to allow room for a standard 9-volt transistor battery.

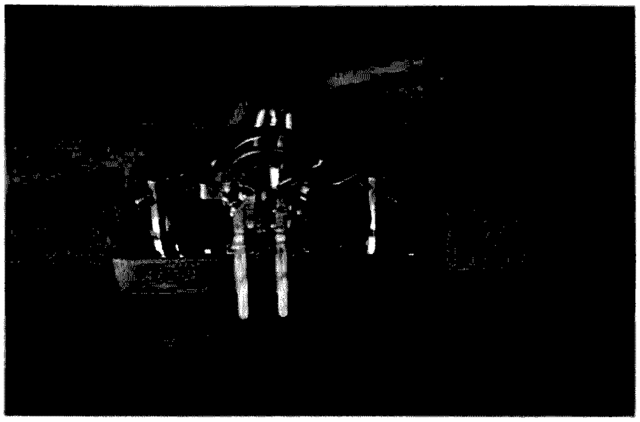
The internal controls are all miniature trimpots. Sidetone frequency is set to 1000 Hz and volume to a nominal level. The sidetone output is really only designed to drive headphones (there is no internal speaker), but the instruction manual points out that a 500-Ohm to 8-Ohm miniature transformer will bring up the volume to a usable speaker level.

There is also an internal control for weighting, factory-set to 3:1. Curtis discourages the use of nonstandard weighting, but provides complete instructions on the use of the control for hams with special requirements as well as for those diehards who insist on making a perfectly good keyer perform something like a grossly maladjusted Vibroplex bug. If you can't resist playing with the weighting, rest assured that it is easily reset to 3:1 by turning the control fully counterclockwise.

A particularly useful control is the maximum-speed trimmer. The keyer is factory-set for a top speed of 50 wpm, but this can be raised or lowered appreciably by adjusting the maximum-speed trimmer to taste. For example, I never send faster than 25 wpm. By setting the trimmer for this slower top speed, I enjoy a much wider range of adjustment with the front-panel speed control.

In the Real World

Curtis's years of experience producing keyers are evident in the design of the K5. It's no use



The Curtis K5 keyer with Bencher paddles. (Photo by KA1LR)

having a portable keyer if it places an unseemly demand on available power. The K5 draws less than 50-uA quiescent current and about 20 mA while keying with an average sidetone level. Turning the sidetone off completely reduces drain somewhat.

The K5 is designed to operate at 9 V dc, but can be operated at up to 20 V dc as long as the battery is removed before the higher voltage is applied. For lower voltages, the relay's current limiting resistor can be shorted out, which will permit operation with as low as 3 V dc input. The voltage range recommended for most reliable operation is 5 to 15 V dc.

Because of the K5's sealed-contact tungsten relay, keying incompatibility problems are a thing of the past. The touchiest solid-state keying circuit (like the one in my Icom IC-701) is keyed without complaint. No more changing polarity when switching rigs, either! The maximum contact rating of 500 V, 1 A at 15 VA should handle your swishing clobber from the fifties with ease. And if you are worried about getting along with a noisy relay, relax—this one makes less noise than the contacts on my Bencher paddle!

Importantly, the circuitry is well-protected against the harsh electrical environment amateur radio equipment often faces. A diode in the power-input line protects the keyer from reverse polarity. Both sides of the output relay are protected against inductive-kickback spikes. Anything and everything that could suffer from rf pickup is bypassed and/or equipped with a ferrite bead. The paddle inputs include debouncing circuitry, and two pairs of germanium diodes protect them from accidental application of voltage.

One potentially confusing feature of the K5 is its availability in two different models. The K5 offers iambic keying that handles like earlier Curtis keyers. The K5B offers iambic keying with characteristics similar to the Accukeyer, AEA, Heath, Nye, and Ten-Tec units. Make sure you order the model that provides the characteristics that you are familiar with. If this is to be your first keyer, the K5B would be your best choice since you won't have to relearn anything when you use a keyer from a different manufacturer. If you ever wish to try an alternate method of "paddling," you can simply unplug the chip and replace it with the other version.

It is hard to imagine a better keyer for the ham who doesn't require a unit with memory capabilities. It should be especially popular with hams who use portable multi-mode VHF and UHF gear. No more sending CW with the mike button to make a few contacts during a meteor shower!

Whenever you use it though, you'll find that the K5 produces code that is indistinguishable from its more expensive and bulkier competitors. And as a ham who frequently tests new transceivers, I find the relay-driven transmitter keying particularly useful. I own several excellent keyers from a variety of manufacturers, but because the K5 never needs rewiring to make it compatible with a new transceiver, it's always the first keyer connected to a new addition to the shack.

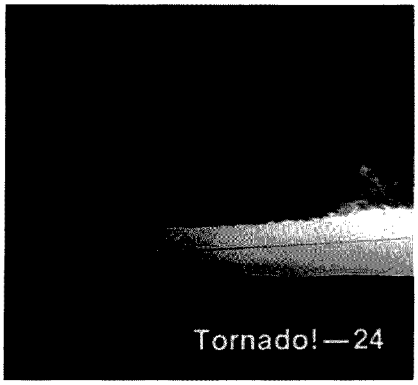
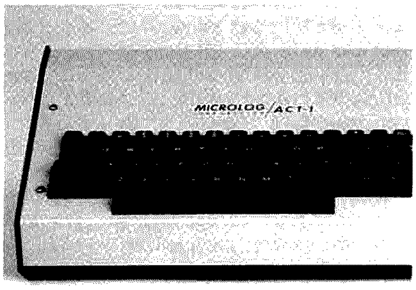
Sinkhole—18



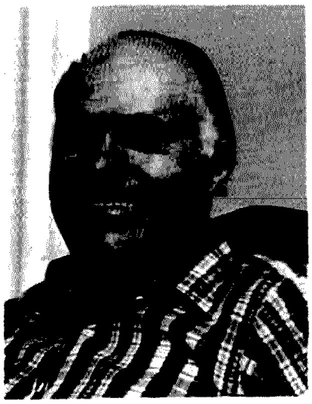
Tornado!—24



ACT-1—120

Cover: This month's cover by Alex Stevens depicts the astonishing 350-mater (1148') rotating tower of French amateur Pierre Avril FØOL. Erected during the spring and summer of 1981, the massive structure tapers from 5.25 meters (17' 2-5/8") at the base to 1.25 maters (4' 1-1/4") at the top. It was designed with the assistance of Swedish engineer Vassa Loppet SL1M and is constructed entirely of scrap metal salvaged from the Saturn V project and Soviet world's fair exhibits. Pierre, who operates mostly CW, is an avid county hunter and holds numerous operating awards. He credits his now potent signal to the use of 6-cm (2-1/4") nitrogen-filled hardline, his trusty TH6DXX, and the selection of a hilltop OTH. This triumph of the amateur spirit is located at Pierre's home in the quiet village of St.-Fou-des-Ondes-Courtes, Dept. de la Haute Tour, southern France. Look for the construction details on this monster in an upcoming issue of 73.

W2NSD/1
NEVER SAY DIE
editorial by Wayne Green



WE'VE BEEN BASHED

Word has leaked out that Dick Bash, the chap who publishes the books with the answers for the FCC tests, is about to bring suit against *QST* because they won't let him advertise his books. Well, I don't know what their excuse is for that. I suspect that they just don't want to help sell a book in direct competition with their *Q&A Manual,* which does about the same thing, only not quite as well.

There was a fuss a little while back when the FCC was reported to have lowered the boom on *Ham Radio* magazine, essentially telling 'em that if they continued to carry ads for the Bash books, the FCC would cut off information for their *HR Reports* (now defunct). The FCC has made no bones about being very upset over what they see as a total defeat of their license exams.

My own view is that Bash's books are one of the most destructive forces in amateur radio. They have removed the last vestige of need for a newcomer to bother to learn even a shred of knowledge about the technical end of things, opening the gates to anyone who can learn the code at five words per minute. We've seen that kids of four can do that, so it certainly is no accomplishment worthy of great pride. And so, while on the one side I see most hams demanding that *only* the code be used to keep out the undesirables, on the other I hear them bitching about the growing mayhem on the bands as new turkeys get on the air.

The Bash books, as far as I'm concerned, are a poison which is rapidly sapping the strength of what was once a proud hobby. If Carrie Nation were around today, she would rip 'em up and let the dealers return them to Bash for a refund. Alas, most hams today can't get their wheelchairs into the ham stores...or maneuver their walkers to the book department. Only the frustrated CBers are making it.

As far as I know, only *CQ* is carrying ads for these insidious publications. The FCC can make rules against them, but how can they be enforced? So Bash goes on reprinting the FCC exams virtually word for word, complete with the answers. He started out at FCC offices interviewing people who had just been through the exam, getting everything they could remember and writing it down. Today I think he depends on cards sent in by people who have just taken the exam. It's a sure-fire way of totally destroying the FCC test...and the fabric of amateur radio. These cheat-sheets have been so successful that a large percentage of the ham clubs who had been giving technical classes to prepare people to pass the test have given them up. Why spend the time and money on classes when you can memorize a few test answers in a couple of hours and fly through the exam?

In turn, this has been keeping newcomers to amateur radio from having to contact the clubs...and has further discouraged club membership. So we are seeing many of our ham clubs dying. Many are becoming geriatric events where doddering old-timers regale each other with tales of long ago triumphs.

If anyone out there really cares about getting amateur radio repaired, if anyone would like to see us be able to provide emergency communications, if you'd like to see us start turning out some new inventions and pioneering new techniques, if you are sick of the crap on our bands...then start *doing* something about it. It is up to *you.* Go down to your ham store and talk the owner into throwing out those Bash books. Tell *CQ* what you think of their carrying the Bash ads. Let's take some steps to make this a technical hobby again. Let's see what we can do to get hams back into building, experimenting, and pioneering.

Let's get our ham contacts more interesting by weeding out the CBers who never grow up. Let's get those technical classes in clubs going again. I want to be proud to be a ham...and so do you.

Carrie Nation...where is your spirit?

THE CD DEBACLE

My editorials on the almost non-existent state of Civil Defense in the United States have apparently fallen upon apathetic and uninterested eyes. I've had virtually no response. Trying to get some life into this desperately needed service is like trying to move the *Queen Mary.*

To go back briefly over the situation: As part of the SALT agreements our politicians, with their usual wisdom and foresight, made a pact with Russia setting up the main nuclear deterrent as Mutual Assured Destruction (MAD). We agreed to not protect our cities and people and Russia made the same pact. Fine idea...if they blast our cities, we'll blast theirs, and no one wins.

As usual with Russian agreements, the first step to implement it was a massive building of nuclear bomb shelters throughout Russia. Well, they've done well with this. If you ever read any news more than the ball scores, you know that the Russian shelter system is an accomplished fact. Perhaps it is time to go back and change MAD to AAD, American Assured Destruction.

It is unlikely that our present government is going to do anything serious to revitalize Civil Defense. They're fighting to cut expenses, not generate them...fighting against the massive social reform expenses. A recent study of Sweden on PBS showed the result of socialism carried to the extreme. Depressing.

Amateur radio has never depended on the government for support. The fact is that in just about every case you can mention, the government has hurt amateur radio when it has meddled with it. Left to our own resources, we would have a much larger amateur radio service, would be years ahead in technology, and our country would not have been passed by

---

NEWS FLASH

On February 17, the Federal Communications Commission approved the release of a Notice of Proposed Rule Making and Notice of Inquiry that could result in a substantial expansion of the amateur HF phone subbands. The Commissioners propose to expand the present 20-meter allocation by 50 kHz, giving General, Advanced, and Extra Class amateurs phone, SSTV, and facsimile privileges from 14.150 to 14.200 MHz. The docket, which is labeled Private Radio Bureau 82-83, has a comment deadline of July 1, with reply comments due August 2. Along with proposing the 20-meter expansion, the Commissioners are seeking comments regarding the expansion of other US phone allocations. *73* will bring you the full text of PRB 82-83 as soon as it is available.

Japan and possibly Russia in technology.

With amateur radio the only practical system for emergency communications, one might think that the government would be interested and perhaps even cooperative. But no, CD is a disaster in most areas of the country. Few CD officials have wanted to cooperate with amateurs, so there isn't much doing as far as organized CD communications is concerned. This has not stopped the CD officials from spending all of the money allocated to their areas, even though most, if not all, of the money is wasted.

We can bring some light into this dark area if readers with personal knowledge of what is happening in their communities will write and let me know. Let's bring this out into the open and see if we can't get some official pressure to improve the situation.

With or without CD cooperation, I'd like to see amateurs set up a national emergency communications system...one which would provide the communications which will be needed in case of the worst. Remember, if we don't have such a system set up and working on a daily basis when there is no emergency, it is not likely to be of much value when things are in an uproar.

With some guidance and leadership, we might be able to get many ham clubs to establish special emergency teams. We'll be wanting to provide communications not only between hams, but also have a system of communicating with most of the other civilian and governmental radio services. This will mean the establishing of emergency communications centers with their own power and equipment capable of operating on a wide range of frequencies.

If any clubs are doing this, we'd like to have some pictures and an article. This might encourage other groups to work along similar lines.

Or would you rather just ragchew and wait, hoping that the Russians will feel sorry for our unprotected cities and be nice enough not to take advantage?

KILLING THE WOODPECKER

Yes, the damned thing is a pain. And it isn't going to go away unless *you* do something about it. We already know what it is. We know where it is. We know

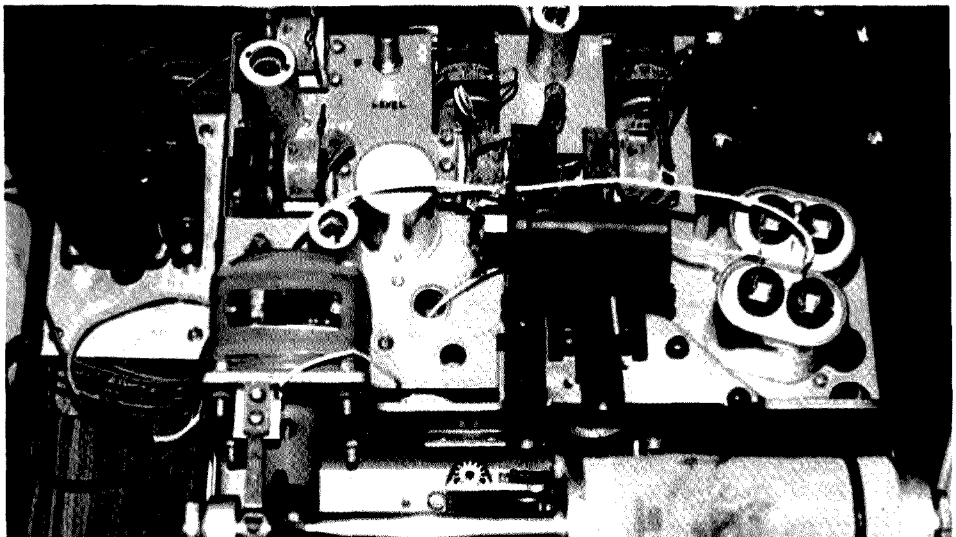
—a cheap and easy conversion



The converted fax unit. The autotransformer is to the left of the deskfax. The motor capacitors are shown between the drum and the power transformer occupying the area formerly used for the exciter lamp.

The Western Union deskfax offers an inexpensive approach to the reception of satellite cloud-cover pictures. This article describes a complete satellite receive system using the deskfax recorder. Little actual construction is necessary and the results can be equal to those of more complicated systems. The receive system and the fax display unit are separate elements and are discussed individually.

Receiver Conversion

The receiver needed here should be capable of FM reception somewhere between 20 and 50 MHz and should be tunable in order to compensate for Doppler shift. A receiving converter is used to bring the satellite frequencies within range of the FM receiver. Several radio sets which qualify are listed in Table 1.

All of the receivers mentioned in Table 1 sell for less than $35 and one of these or a similar receiver should be obtained first. Then it is a matter of selecting a converter with an output which falls within the tuning range of the receiver. The converter crystal determines this output frequency.

One attractive prospect is the use of a converter which reduces the incoming signal by exactly 100 MHz. A satellite signal transmitted at 137.45 MHz is thus converted to 37.45 MHz and the digit one is mentally added to the front of the receiver dial. However, it should be noted that receivers which cover 28-39 MHz usually sell for about ten dollars more than those which tune 20-28 MHz. In this case, the frequency conversion should be increased to 115 MHz for an output of 22 MHz. The converter should not change the satellite signals in such a manner that would permit interference from Citizens Band transmitters. That is, a frequency difference of 110 MHz should be avoided.

I use an R-108 military surplus receiver and a converter purchased from Hamtronics Co. The receiver is more sensitive than its BC-603 counterpart, but it requires a filament supply of 6 V dc at 6 Amperes as well as a 135-V dc B-plus supply. The R-108 does have some nice features to make it a worthwhile purchase. One is a fixed level of audio output that is independent of the speaker volume control. The fixed output can be fed directly to the deskfax recorder. A tuning aid in the form of an oscillator is also included.

A simple turnstile antenna, consisting of two crossed dipoles with reflectors, was made from a wooden mast and some ¼-inch aluminum tubing. RG-59 was used as feedline. This antenna provides excellent signals and good pictures can be obtained on overhead passes. Once the satellites have been heard, the orbit calculations are quite simple.

Some simple DXing and notetaking will reveal enough information for short-term predictions of the next satellite pass. Commercially-available satellite-tracking kits such as the one the ARRL provides for the OSCAR satellites are helpful in the initial efforts to understand orbital mechanics and the unusual behavior it imparts to satellite paths.

The Deskfax conversion system described in the text is pictured here. Although the deskfax is shown with the top cover in place, it is better to have the cover removed for actual use. The picture also shows the FM receiver and the converter, preamp, and power supply for the solid-state circuits.

Picture Display

The deskfax conversion is almost as simple as the receiving system. The deskfax unit is used essentially as is, with only minor modifications made for convenience. Since no type of transmission is desired in this unit, some of the transmit circuitry is disabled or removed.

Once the deskfax unit is obtained, a few operational checks should be made. The first check is to see that the unit functions when the incoming and outgoing buttons are pressed. It should be noted which of the relays operate in each mode, paying attention to the incoming function.

A relay marked LR, located near the back of the unit, must be operated manually as the incoming switch is pressed. A rubber band stretched around the LR contact wafer and attached to the 6AU6 tube, located between relays TR and ACK, provides a conve-

Radio Set	Type	Frequency Coverage	Notes
BC-603	military surplus	20-28 MHz	sold w/o power supply

BC-683	military surplus	28-39 MHz	sold w/o power supply
R-109	military surplus	28-39 MHz	sold w/o power supply
Radio Shack VHF Pro	police band	30-50 MHz	solid state, power supply included

Table 1. Possible radios for receiver conversion.

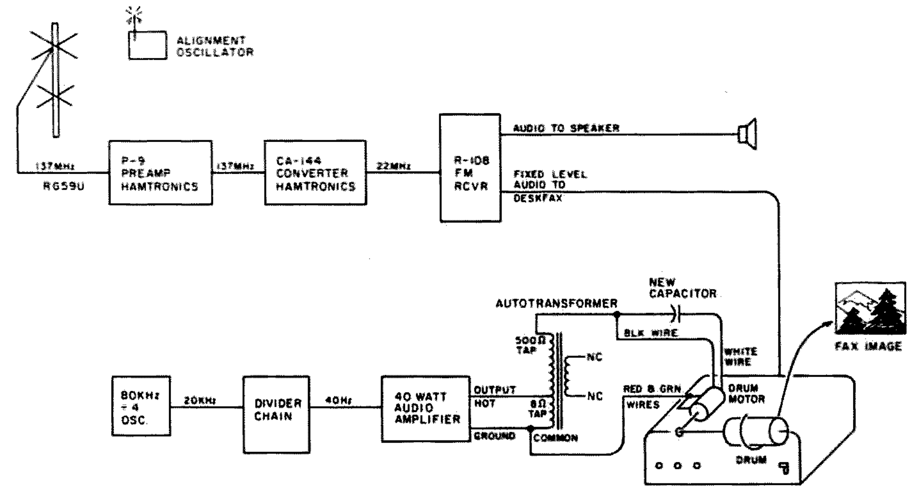

Fig. 1. Block diagram of the complete fax system.

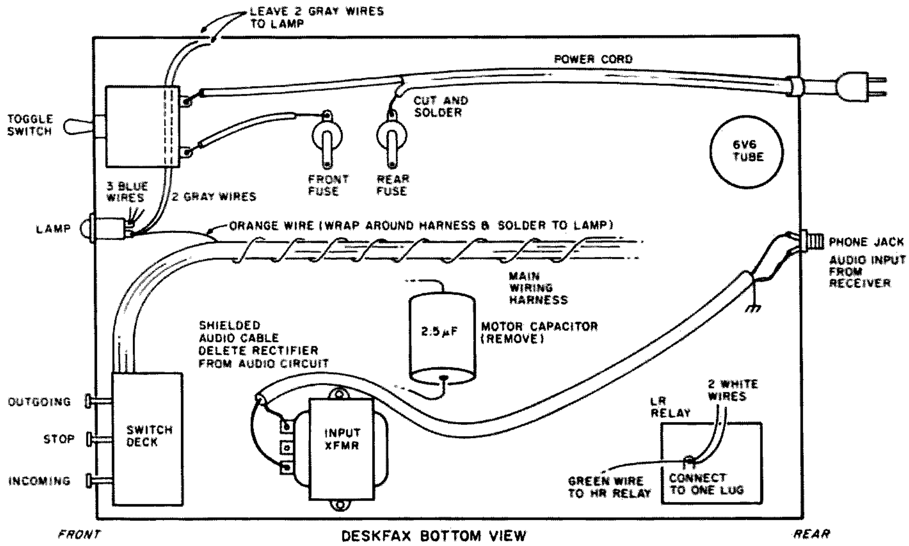

Fig. 2. A few simple wiring changes are needed to modify a deskfax unit.

nient way to anchor this relay into operation. Now relay PWR should close, and the 6V6 tube will start to glow. As the 6V6 tube warms up, a number 47 lamp in the B-plus power supply will also start to glow, dimly. The relay marked HR will close and the rotating drum will start to advance toward the opposite end of the fax machine. At the end of the drum's travel, a screw located on the forward end of the drum touches a post which shuts off the incoming switch deck, resets the relays, and allows the drum spring to return the drum to its original position.

If all this occurs, the unit is probably OK. If the 6V6 or HR relay fail to operate, check the cathode and plate voltages on the 6V6. The cathode should have 16-20 V dc and the plate should have 280-300 V dc. Failure to read these voltages indicates that one of the larger resistors in the deskfax is opened. The grid voltage on this tube is practically nil.

To the rear of the drum is the stylus arm. A small aluminum clip containing a steel wire stylus fastens to this arm. The incoming check should be repeated again, this time to verify operation of the stylus. With a piece of fax paper on the drum, begin the testing procedure again. At the rear of the deskfax, between relays LR and ACK, there is a pot listed as P1. After the drum starts moving, P1 should be advanced until the stylus begins to burn the fax paper. If the fax paper does not burn, try placing an audio signal across the end taps of the transformer located near the incoming switch deck. The fax paper will burn according to the intensity of the audio signal.

A new stylus, if needed, can be made from a steel wire cut from a wire brush or a wire wheel. It is not necessary to solder the new wire to the old stylus clip; merely route the new wire though the holes that are in the clip, then install it in the holder. Using this method, it is possible to attach a 2-inch-long wire and extract it toward the drum as it burns down. In this way, the stylus need not be changed so often.

Now the deskfax is ready for conversion. First, remove the wires that are connected to the coil of LR. Remove the buzzer and the ACK push-button switch. The orange wire which follows the switch deck harness should be attached to the ACK lamp and the jumper from the push-button to the lamp should be deleted. The short gray wire should also be removed. The ACK lamp will now have one side connected to 3 blue wires and the other side will have 2 gray wires and 1 orange wire. The ACK lamp will not light. A toggle switch should be attached where the push-button was mounted. Unsolder the power cord and move it farther into the chassis until one wire will reach the new toggle switch. Then solder that wire to one side of the switch. Trace the remaining wire back to the rear power fuse. Cut the wire there and solder it to the empty terminal on the rear fuseholder. Using the piece of power cord that was just cut off, connect the empty terminal of the front fuseholder to the remaining terminal of the toggle switch. This will complete the wiring of the main power switch.

Remove the exciter lamp assembly and its transformer. If you do not desire to manually operate relay LR, it may be left on permanently by soldering the contacts together or jump-

Reader Service for facing page ✓303→

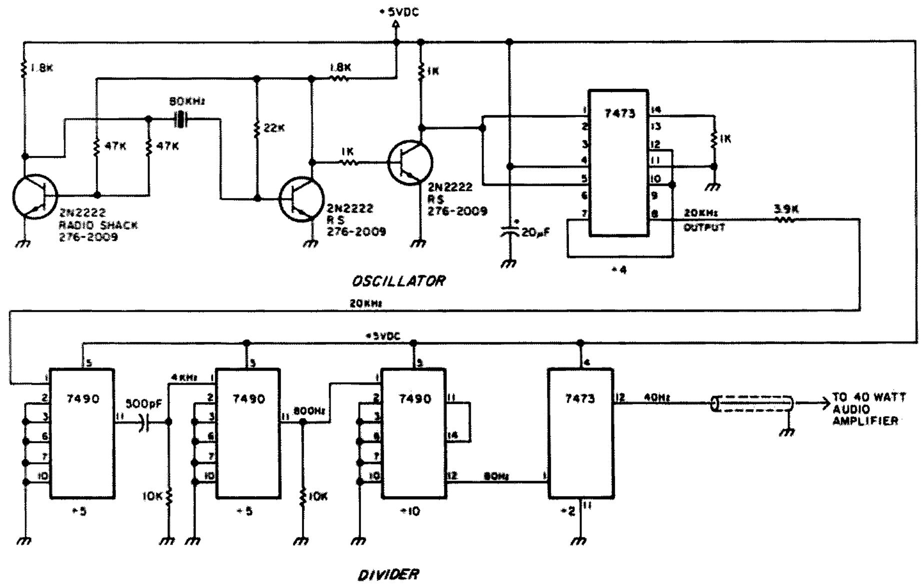

Fig. 3. This 40-Hertz signal source drives an audio amplifier which powers the deskfax drum motor.

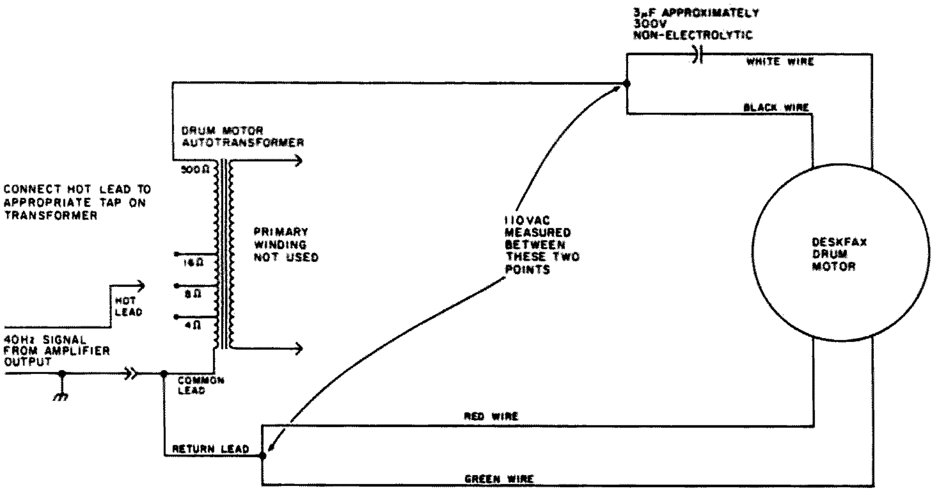

Fig. 4. The 40-Hertz signal from the amplifier is stepped up to run the motor. A dc voltmeter placed at the output of the amplifier will read approximately 12 volts going into the autotransformer. A lower voltage indicates the amplifier does not have sufficient output power to drive the motor.

ering them. The unshielded leads of the input line leading to the input transformer should be replaced with shielded audio wire. The original wire exited through a hole in the rear of the chassis. This hole will accommodate a phone jack very nicely.

Up to now the conversion steps described have been for the sake of convenience and could be bypassed if desired. But the final step is a must. There are four wires that lead from the gray drum motor located at the top of the fax machine. Trace these wires as far back from the motor as possible, then clip them loose. This should only be done *after* the fax machine checks out completely. The white wire will attach to a 2.5-μF capacitor located below the exciter lamp transformer and this capacitor should also be removed.

Originally the drum motor turned the drum at 180 rpm; this will not synchronize with any 120-rpm fax signals presently used on the satellite bands. In order to minimize the cost and complexity of fax systems, a plan was long ago devised which makes use of the existing motor by altering the frequency at which the motor operates. This is accomplished by replacing the 60-Hertz line voltage with one operating at 40 Hertz. This system is by no means new, but few details have ever been published on how to go about it. This approach becomes more desirable when fax units which operate at 120 rpm are priced.

My circuit consists of an oscillator and a divider chain which together produce a 40-Hertz square-wave output which is fed to an audio amplifier, where the signal is coupled to the drum motor through an autotransformer. A square wave is necessary for the divider chain to function properly.

The oscillator circuit was originally designed by Ken Cornell as part of a transmitter for the license-free 1750-meter band and was first published in the newsletter of the Longwave Club of America. It is with Ken's kind permission that the modified circuit is included here. The circuit was selected for its stable square-wave output. The oscillator and the divider chain both operate from a five-volt power supply. The Cornell circuit makes use of a crystal operating at 80 kHz and divides the signal down to the 20 kHz the divider chain requires. Since the oscillator circuit was designed for a much higher crystal frequency, it may take a few seconds warmup time to get the oscillator perking. A suitable substitute for Ken's design would be an oscillator operating at 100 kHz, divided by 5. Only the 80-kHz crystal and 7473 IC chip need to be changed. This should be considered if a 100-kHz crystal is more readily available.

The divider chain consists of a few components and a handful of ICs. The frequency divisions may be verified by monitoring the outputs of each IC. The 40-Hertz output is then fed to an audio amplifier. I used a tape recorder am-

The Sinkhole That Ate Winter Park

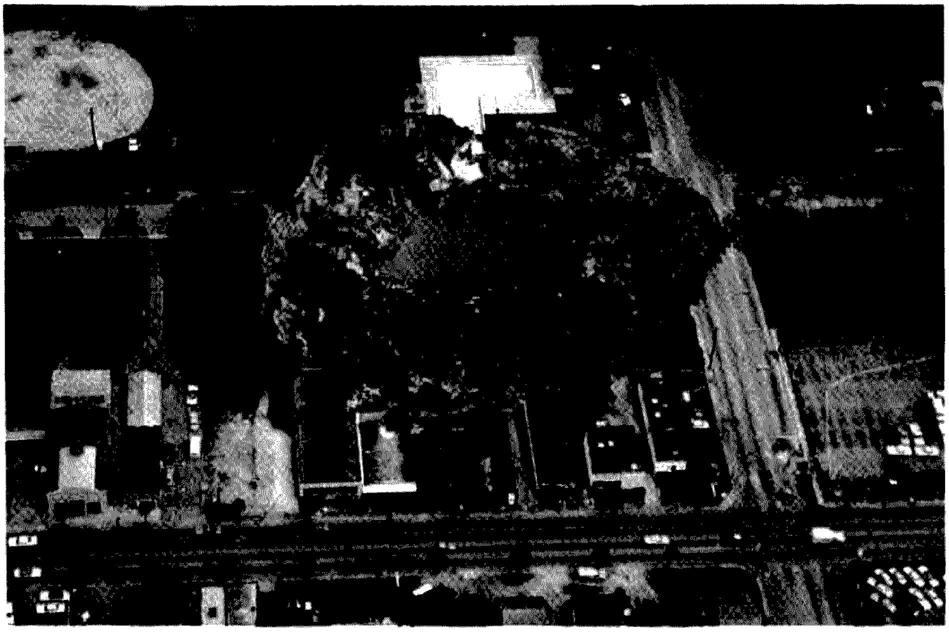
—hams vs. hole

When I locked the door to my business on the afternoon of Friday May 8, 1981, looking forward to a weekend of relaxation, I did not know that within 48 hours my faith in terra firma would be shaken forever and that my faith in the value of amateur radio would be renewed.

Winter Park is just across the city line from Orlando and right in the center of the state of Florida. The area is noted for the many lakes which dot the landscape. These lakes are fed from the massive Florida aquifer, a spongy, water-soaked limestone bed that lies under the whole central area of Florida. During times of drought, the water level falls and the porous rock can collapse. When this happens on a large scale, the resultant depression is called a sinkhole. It appears to be a monstrous crater to the center of the Earth which is devouring its surroundings. It is both frightening and, when occurring in an urban area, dangerous and disastrous.

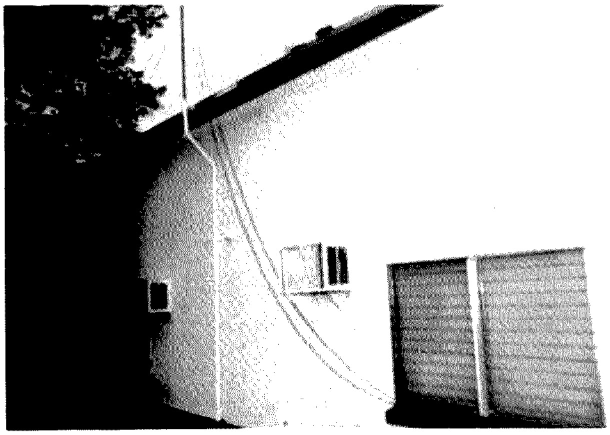
Early Saturday morning, I was behind my lawnmower enjoying the Fruits of Suburban Living, the Right to Life, Liberty, and the Pursuit of Crabgrass, when the ringing telephone offered a respite from the sun. It was an employee of mine, calling to find out if I knew anything about my shop's condition. She had heard that the area was sinking.

I called the police immediately, but they had no information to give me other than the fact that there was a sinkhole; they advised me to stay away. That same information was confirmed by a call to the Fire Department. I frantically called City Hall—no answer. Then a thought flashed in my mind and I raced to the shack, flipped on the 2-meter rig, and dialed up the local repeater. I called for a break, and there on frequency and at the sinkhole was a ham friend, Ed Cox WØRAO/4. He had just happened to be passing, noticed the emergency vehicles, and stopped for a look! Ed described the activities and area of involvement and then advised me on the best way to get into the area.



Armed with this information, I raced over from my home for an inspection. The area looked like a scene from a B horror movie. Fairbanks Avenue, normally the main east-west road through the town, had a six-block section barricaded. Many emergency vehicles skirted the perimeter. Police had established a crowd-control line. And there in front of the widened eyes of hundreds of spectators was a gaping cra-

Reader Service for facing page ✓15→



ter. One almost expected some primordial beast to rear its head from the depths. The pit was 400 feet across, over 150 feet deep, and contained a dry cleaning plant, a TV store, a print shop, six Porsches, and the back end of an auto repair shop. For dessert, it had eaten a three-bedroom house, parts of two streets, and an Olympic-size city swimming pool.

I stood in the front door of my shop—just 125 feet from the rim—in total disbelief. I had been a resident of central Florida for awhile and knew that although sinkholes were not too uncommon, this gigantic one was very unusual. A passing police officer said that three other smaller sinkholes had opened up elsewhere in the county.

As the crater began to assume a round rim, however, I felt that perhaps my property would be saved. And when a telephone utility worker came by and muttered that if a nearby main trunk line went, south Florida would be sending letters for a while, I got an idea.

Here was the prospect of a communication emergency and mounting national and international interest. I should set up a portable amateur station on my property near the hole! I also had easy access to the local geologist's temporary field headquarters, where complete factual information would be available on this and other sinkholes.

I made the ten-minute trip home and rushed into the shack. I wondered—what kind of antenna? What rig? What about power? I would have to homebrew an antenna. I grabbed some RG-58/U from a pile of Hamfest Fallout. I also found some 450-Ohm ladder line. In the utility room, I had a coil of Romex house wiring, scraps of stranded copper wire, and an old extension cord. I borrowed a marine battery from a neighbor. I was certain that I could do something with all this wire, but to be sure, I took the matchbox tuner. I also chose my tube-type rig (Drake R4B and T4XB) rather than my new solid-state rig because of the reputation of tubes in the finals during high swr conditions.

Finally, I took along my dummy load, a ham's most important device. I knew I could tune the rig with the known 50-Ohm value of the dummy load.

My station wagon looked as though I had just come from a binge at a hamfest. My XYL came running down the driveway with a D-104 mike and a CW key. She advised, "Be careful, Honey, and you need these, don't you?" I could see bits of tears in her eyes, and, had I waited, I think she would have renewed her pledge to get her ham ticket.

As I drove back to the shop, I heard national network news on a local station exclaim, "And in Winter Park, Florida, a massive sinkhole continues to swallow the business district. . ."

I screeched to a halt in my parking lot and assembled the gear in the front room of the shop. In the office, I had a fresh copy of the May issue of *73*, and there in the pages was an article on coaxial dipoles! I fished out the RG-58/U and home-brewed a 20-meter coax antenna. My emergency mast was a piece of 1 × 2 wood stuck down in the toilet vent pipe on the roof. I taped the center of the dipole to the mast using duct tape and used twine to support the ends, one strung from a tree limb and the other from my business sign. The feedline came in through a window.

A quick hookup to the power supply, and the tubes began to glow. The antenna worked! I heard the reassuring crackle of CW, then a fast load-up, and I was on the air. The band was down at the time, but I was reaching New York and the midwest with 599 signals. My Advanced class ticket was barely a month old, so I went up to the phone bands.

During the next several hours, the amateurs I contacted by CW and phone were very interested in the facts about the sinkhole and surprised that there was an amateur station so close to the event. They asked about relatives in the central Florida area, and we would tell them what we knew about the other sinkholes as well as ours. Several amateurs were concerned about their properties in Florida, and we provided information regarding water rationing in southern Florida as well as on sinkhole damages in the central areas.

Two days later, the geologists and city officials felt that the massive hole was stabilized and only minor expansion would continue. They decided to open Fairbanks Avenue, but for pedestrian traffic only. The crowds were huge. The Great Winter Park Sinkhole became the number one attraction in central Florida. We estimated that over 35,000 people flocked to the area to see the awesome sight. I made some quick arrangements with a T-shirt firm and reopened my business to cater to the crowds. On the front counter remained my portable rig, and we continued to operate, to the delight of the crowds.

I was forced to remain in my building for long hours during the initial collapse phase so that I could respond to the city engineers and be informed of the status of my property. After

Reader Service for facing page ✓331

the worst was over, I decided to experiment with the variety of materials I had and see just exactly what I could accomplish in antenna design with the barest of essentials.

I was pleasantly surprised to find that almost anything can be made to radiate. The antenna tuner was worth its weight in gold. Using coax feedline and standard dipole lengths, I constructed radiators from stripped Romex house wiring, lamp cord, and even a piece of transformer winding. The most novel was a length of kite-string doused with salty water! We assembled it on the roof and sponged on the brine. It loaded up fine, but then the swr meter went crazy. The observer on the roof yelled down, "Hey, the water is drying up!" Either the hot sun or the rf was evaporating the salty solution. We tried loading the string again at night, but evaporation was still rapid, so we never did conclude what the real culprit was. Perhaps it was a combination.

One fascinating observation was made with an end-fed zepp. The capacitance of the antenna and tuning values seemed to follow a slow shift while operating during the day and evening. I was baffled. The 40-meter antenna hadn't moved, we hadn't readjusted the rig, and nothing seemed to have changed. Late in the evening, however, a geologist was updating me on the hole and mentioned that the water was slowly rising in the bottom of the sinkhole. Could it be that the capacitance to ground had been changing and it was detected by the tuning values of the antenna? Since the level of water in the hole was the basic level under the building and antenna also, perhaps we had discovered a way of measuring the water table using antenna values!

There did seem to be a correlation, and the head geologist was excited about the prospects. This was real ham radio—experimenting, learning, and discovering!

On the operational side, I learned a lot of things since most of the time I was in the middle of a pileup. I found it difficult to write down the calls and reports and work the PTT button or the key. I soon developed the skill of writing with the right hand and working the PTT with the left. A footswitch would have been nice!

I gave up on VOX action due to the local noise level. On phone, rather than working one station at a time and then calling QRZ, I copied down all the calls I could hear within about 10 seconds and, as the action died down, repeated their calls. As soon as I had a list of a dozen or so, I worked each of the calls on the list. I found this system to be much more efficient than creating a shouting match after each call. On CW, I found the operators to be a little easier to work. I also discovered that the pileups occurred on CW down around 14.025 to 14.030, the secret hideout of the fluent CW ham.

To encourage participation with us, we developed a certificate, the W.A.S., or "Worked All Sinkholes." This bit of wallpaper served as a QSL and as an item to create interest.

Armed with a hemisphere map, I began to plot areas where our signal was reaching at various times of the operation. Sure enough, you could see the zones as the reports came back to us. I reconfirmed that by raising the antenna one lowers the angle of the radiation and thereby changes the area of coverage.

I continued to learn things back in the shack. I began to make lists of the things to remember during portable operation: Remember a box of spare fuses! Don't smoke around a battery; the bubbles are hydrogen! When you do run an ac power line, tape it down so that you don't trip over it. Little pieces of colored tape help to code things such as ground wires, coaxes, and connecting cords. Be sure to log all third-party traffic. Be as neat as possible on your main log or you find yourself wondering whether it was a U or a V, and what was that other letter?

I was amazed at the reaction of the general public to the operating amateur station. They seemed interested in the phone operation and somewhat confused by the CW. Using very unscientific sampling methods, the "sinkhole poll" showed that fewer than one in ten realized we were operating an amateur station. Only those who had a relative or friend in amateur radio understood the capabilities of amateur communications.

We did find spectators who were fascinated and very interested, however—maybe two out of ten people. Many were youngsters and teenagers. We furnished the names of several local amateur clubs, a local supply company, and magazine addresses. We wished we could have offered them more information. It is our opinion that amateur radio needs to do much more self-promotion and training of interested newcomers. The type of high-visibility operation that we carried out is a useful technique for raising the level of awareness of amateur communications in the general public.

As a final note, I must say that the sinkhole experience has been one of the most rewarding events of my life, and I am happy that amateur radio was a big part of it. I used to dream about the thrills of a far-off DXpedition and some remote island with waves crashing against a rocky beach.

There I was, in a tent, with the rigs fired up. As I sipped on coconut juice and stared at the big beams on temporary masts, I could hear half the amateur radio world calling me, amidst the cries of the seagulls! Ah, what a life!

Well, now I agree with Dorothy when she told the Wizard of Oz that she had learned her lesson. If I ever go searching for someplace special, I need only look in my own backyard! Sooner or later we will all get a chance to be in the middle of action, and we need to be prepared. Your chance may be next! ■

The Special Sinkhole Crew Advisers and Helpers

Joe Lewis WB4WPP	Ed Cox W0RAO/4
Gilbert Potyandy K4ISK	Jack Leavitt KA4ATV
Dan Martin KC4GO	Fred Hopkins N4EDM

Joe Lewis demonstrated his skills at a pileup that he learned while in Saudi Arabia as a field technician. Gilbert kept the rigs in repair and offered his technical skills. Danny Martin claims he is going to patent his special Toilet Vent Mast! Ed Cox first spotted the hole, and maintains the 2-meter link. Jack Leavitt and Fred Hopkins kept up the local interest and worked on the certificate.

The schedule now is sporadic, but normally is around the lower end of 20-meter CW (General portion) and 20-meter phone. To offer Novices and Technicians a chance, we work the lower end of 40 meters and 15-meter Novice CW. An SASE will get you the regular schedule by the month.

Operation Skywarn

—tracking tornadoes with two meters

Bill Richards WB5ZAM
1925 Juanita St.
San Angelo TX 76901

The following is a true and factual account, to the best of my recollection.
Time: 1900 hours local, on a partly cloudy day in late May.
Location: San Angelo, Tom Green County, Texas.
Frequency: 146.34/.94-MHz repeater.

"Well, guys, I'm tired and both my batteries and the ones in my talkie need a good night's recharge, so I'm going to pull out. If that cloud to the west looks like it's going to do anything, holler. I'll have the radio on but just monitoring. KA5BNJ and the group, this is W5FZY clear, adios."

"OK, Elmer, we'll see you. W5FZY clearing, this is KA5BNJ. Pick it up Noel. WD5BHX, this is KA5BNJ."

"Break! Break!"

"Go ahead break-break, this is KA5BNJ."

"Sorry to interrupt, John, but the Weather Service just issued a tornado warning for the western part of this county and Irion County [directly to the west of Tom Green County]. At 6:45, DPS [Department of Public Safety] reported a tornado on the ground 10 miles north of Mertzon [25 miles southwest of San Angelo] with an apparent northeasterly path. If you don't mind and there are no other volunteers, I'll go ahead and assume net control and activate the Skywarn Net."

There were no volunteers.

"This is WB5ZAM assuming net control for the Concho Valley Severe Weather Net. Do we have anyone on who has information for the

Is this a tornado? Members of the Concho Valley Severe Weather Net were not sure, but they kept a close eye on the ominous clouds.

net regarding the severe weather in the Mertzon area? If so, please call net control, WB5ZAM."

"This is K5JEZ Mertzon. Bill, we've got winds at 30 to 35 miles per hour from the west and northwest, with light rain. We aren't able to see very far to the north, but there are two large thunderheads to the west and northwest of me."

"This is W5RSV mobile, and I'm about 10 miles northeast of Charlie, and those clouds he's talking about are really building fast. It hasn't started to rain or blow here yet but those clouds are very dark and it does appear to be raining over towards Mertzon."

"Thanks, Charlie and Marion. This is WB5ZAM, net control for the Concho Valley two-meter Severe Weather Net, do we have any other reports of severe weather or anyone who can go to the Weather Service and man the station there? If so call WB5ZAM, net control."

"This is WD5BHX. Bill, if no one else can go, I'll be free here in a little bit and will go out, but I'm handie-talkie portable in the mall now. WB5ZAM, this is WD5BHX."

"Thanks, Noel. Is there anyone able to man the station at the Weather Service, please call now. If there are any other reports of severe weather, please call now. This is WB5ZAM, net control for the Concho Valley Severe Weather Net."

No volunteers spoke up.

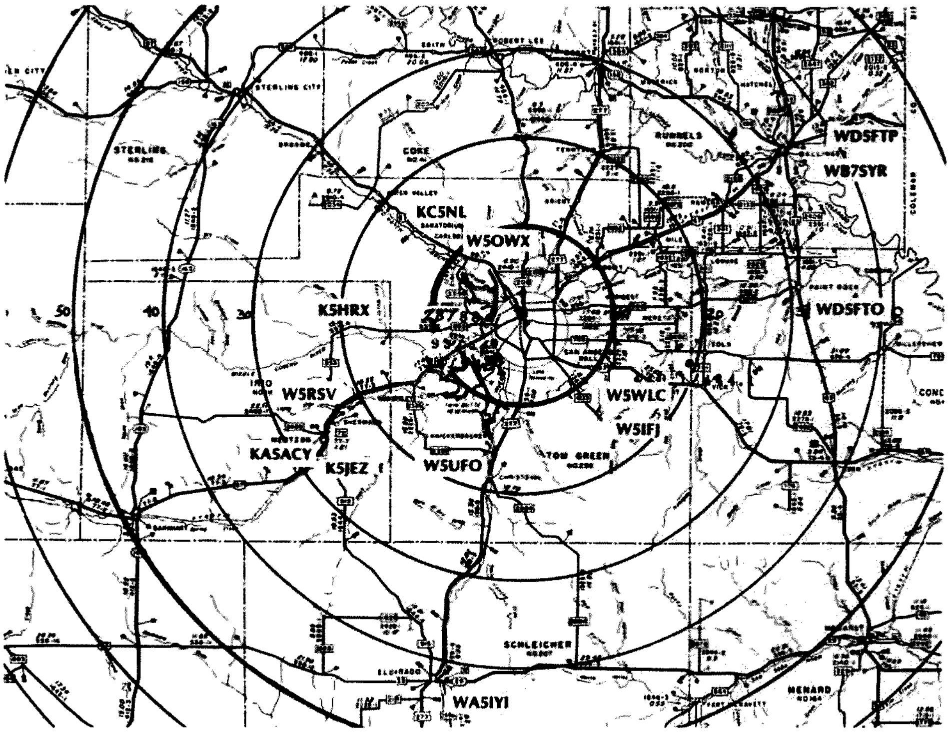
"No takers. Would you mind, Noel? I know Art could use someone experienced with the rig and the net."

"We'll be en route very shortly. WB5ZAM, this is WD5BHX."

"Thanks, Noel. Do we have any other net members with reports of severe weather only? Please call net control, WB5ZAM."

"KA5BNJ."

"W5OWX."



San Angelo, Texas (Tom Green County) and surrounding counties, with the locations of local hams. The rings mark ten-mile intervals from San Angelo.

"Break. This is Art at the Weather Service, W5QX."

"Go ahead, Art."

"Gentlemen, we have a tornado sighted by a DPS trooper, 10 miles north of Mertzon with an easterly path. We also have a line of thunderstorms of marked severity extending from 20 miles northwest of Mertzon to 20 miles west of Ozona, with a path of movement to the east and northeast at 20 miles per hour. These contain heavy rain and hail and do indicate tornadic-type winds aloft. This is W5QX."

"Thanks, Art. We have activated the net and Charlie reports 30- to 35-mph winds with light rain at Mertzon, and Marion reports light winds without rain 10 miles northeast of him. He does report heavy thunderstorms to the west. Thanks for your information and we do have someone on the way to man the radio for you. W5QX this is WB5ZAM, net control for the Concho Valley Severe Weather Net. Do we have—sorry, John, KA5BNJ."

"Bill, we have light rain and a westerly wind at 10 to 15 miles an hour here at Carlsbad [20 miles NW of San Angelo]. WB5ZAM, this is KA5BNJ."

"Thanks, John. W5OWX, WB5ZAM."

"Bill, the weather is about the same here, but I can hear thunder to the west and northwest of me, here in Grape Creek [12 miles NW]. WB5ZAM, this is W5OWX."

"OK, Al. This is WB5ZAM, net control. Do we have other check-ins with severe weather reports only? Please call WB5ZAM, net control."

"This is K5JEZ."

"Go ahead, Charlie."

"Bill, the wind has changed to the west and northwest, at 38 to 40 miles an hour—no, there's a gust to 50 miles an hour, and we have heavy rain now. If I lose power, I'll go to the mobile and be right back. WB5ZAM, this is K5JEZ Mertzon."

"OK, Charlie. Art, did you copy? W5QX, WB5ZAM?"

No response.

"WD5BHX?"

"Yes, Noel?"

"Bill, I'm en route to the Weather Service now. Art probably heard that report but was unable to reply as he went back to the radar. I'll have the radio manned very shortly. WB5ZAM, WD5BHX."

"OK, Noel. This is WB5ZAM, net control for the Concho Valley Emergency and Severe Weather Net. Do we have other reports of severe weather?—and if not, we'll begin taking check-ins from portables and mobiles, then we'll come back to the fixed stations. This is WB5ZAM."

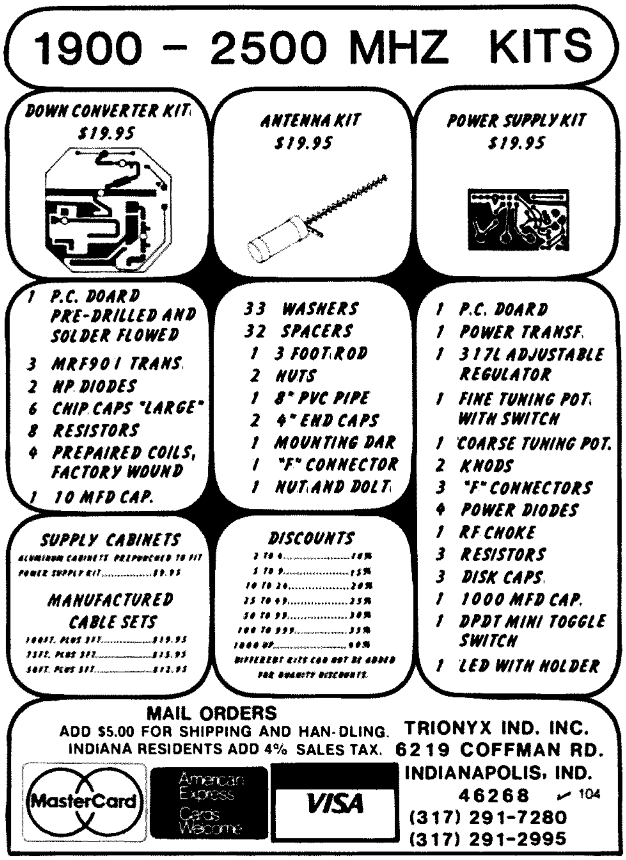
"W5RSV."

"K5JEZ."

"Yes, Marion?"

"Bill, the winds are buffeting the pickup pretty good now and we have a very heavy downpour here. Over."

"OK, I'll note that to Art. Go ahead, Charlie."



"Yeah, this is K5JEZ. The rain has let up some, but it's still pouring and the winds have settled down to 25 to 30 miles an hour, out of the west."

"Thanks, Charlie. K5JEZ and W5RSV, this is WB5ZAM, net control . . ."

And so it went, with thunderheads building to the west and southwest and moving in our direction. We had 46 check-ins: 18 portables, 12 mobiles, 14 fixed, and 2 via telephone, and we watched clouds for just over three hours as they built up and then dissipated.

This quick response on the part of local amateurs was not due to our working as communicators, but due to the weekly practice sessions, where everyone gets a chance to check in, test antennas, and even call the net, to get the hang of calling up the group and maintaining the net. From mid-April through mid-June, we get the real thing with frequent storm development and the possibility of severe weather developing. We watch not only for the Weather Service-NOAA, but for ourselves, the local media, and (you would be surprised who listens to the repeater frequencies during severe weather!) the numerous shortwave listeners.

Due to the size of the area we need to watch for threatening storms, we in the Concho Valley have tried to get the best repeater coverage possible and to keep all amateurs informed of the frequencies and nets. Our net members include lawyers, nurses, ranchers, retirees, salesmen, housewives, Armed Services personnel, executives, and college students. We will have check-ins from as many as 70 air miles away and as close to the repeater as two blocks. The storms that affect us can build near Ozona (70 air miles southwest), or to the northwest (near Carlsbad or Sterling City), or sneak up on us from the east, from Paint Rock or Ballinger, and can include everything from rain and wind to hail, high winds, and tornadoes.

Basing our techniques of cloud-, wind-, and rain-watching on the training provided by NOAA's National Weather Service, we are able to provide accurate information to the Weather Service and hence keep it aware of conditions on the ground under the clouds, an area where the Weather Service radar cannot tell the difference between blowing dirt and hail. To date, we have provided not only basic information on the storms but also have been able to act as indicators of the severity of storms, including the severity of the winds and actual amounts of rainfall. We also have been able to give aid when the radar at the Weather Service was inoperable, giving warnings of high winds and hail as a cell moved into the area.

We found that the best way to keep everyone current (as to who lived where in our area) was to publish a directory of local hams and take a highway department map and overlay it with concentric rings, approximating by tens the aeronautical miles from San Angelo. The map also has the sites of the three 2-meter repeaters and the site of the 450-MHz repeater. We then took the maps and used them to coordinate tests on the emergency-powered repeaters so as to test where we could reach the repeaters with what level of equipment (i.e., with a one-Watt handie-talkie, or 10 or 25 Watts, or if a directed array was necessary). All net and club members then were given maps, a list of current net check-ins, and the opportunity to call up the net in the weekly practice sessions.

Since the storms take fairly consistent paths, we found that a map showing the area southwest and west would serve better than a true circle around San Angelo. The map gives the net control an idea of who lives where in relation to a storm cell, and net control thus is able to ask these specific individuals for information on the cell, whether it is moving toward them, away from them, or around them. Then the net can ask for mobile stations to move to points paralleling the projected path of the storm. Since we have only about 60 amateurs active on 2 meters, this map gives the net control an idea of where each member is—especially those in the outlying towns.

The continuing improvement in the educational services from NOAA has helped to train more and more amateurs in the Skywarn system and has increased the number and accuracy of reports during the severe weather months. We also installed equipment at the Weather Service, giving them ready access to the net frequency, and have worked with them to get amateurs into the Weather Service during inclement weather to give them a trained communicator to exchange information between them and the spotters of Operation Skywarn.

So, the next time you hear a net call-up on 2 meters (or if you haven't tried 2 meters), go set your FM public service receiver or scanner to the net frequency; when the next severe weather system blows in, you can watch the storm through the eyes of others and know whether you are going to get a springtime shower or a frog-strangler. You, too, may want to join the "professional" amateurs on the Severe Weather/Operation Skywarn nets and help keep an eye on the storms. ■

Measure Ohms with Your Calculator?

—yes, and accurately, too!

Undoubtedly the dumbest electrical measurement made on a multimeter is the one on the high end of the Ohms scale, where the figures are so crowded together that what you read is more a matter of faith than reality. And then there's the zeroing problem—was the meter zeroed when you started?

Now, at last; there's a better way that doesn't crowd readings or require rezeroing . . . a linear, digital ohmmeter with great high-resistance sensitivity that exceeds the 20-megohm limit of many commercial digital multimeters!

But the best news is that you can put it together yourself in a cheap pocket calculator! Nowadays these little four-bangers are frequently on sale for less than the cost of their individual parts. This amounts to the manufacturer doing most of your assembly work and providing a professional-looking, compact case as well. Try agonizing through the alternatives and you'll quickly see what I mean in terms of the cost/benefits ratio. All this

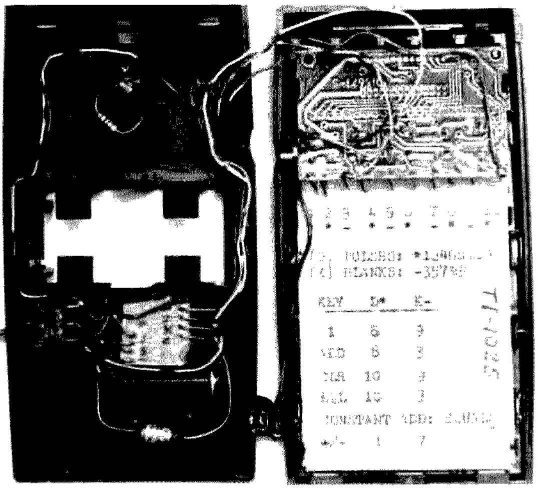

Photo A. Clamshell view of the completed calculator transformation. The final range capacitor is a 1-microfarad tantalum between switch and module. Just four wires connect to the calculator circuit proper; they were left long for strain relief. The assembly is ready to be closed up and used.

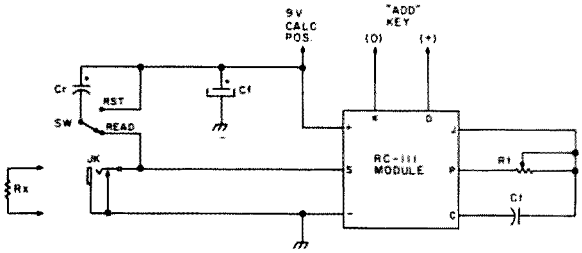

Fig. 1. Circuit for converting calculator to measure resistance.

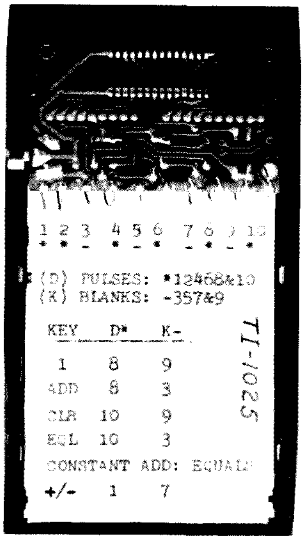
Parts List for Fig. 1

Cf—Filter capacitor, 10-100 uF, electrolytic
Cr—Range capacitor, polyester, 1-2 uF (see text)
Ct—Timing capacitor, polyester, .05 uF
Rt—Timing resistor, minipot, 1 megohm
Rx—"Unknown" or calibrating resistor, 1 megohm, 1%
JK—Phone (test) jack, miniature, w/plug and test leads
SW—Switch, SPDT, miniature, bat-handle toggle
Above parts are readily available from normal sources.
RC-111 Module—Available from Kaltek, Box 7462, Rochester NY 14615 ($14.62 ppd., plus NY state sales tax if applicable).

Photo B. Ten wires connect the keyboard to the calculator chip/display board. An oscilloscope from ground to each wire in turn identified the wires carrying digits pulses. The scope between each of these wires and each of the other "keys" wires showed which key joined each pair. The table shown cracks the code for the keys of interest. The module connects to the constant-add pair, numbers 10 and 3.



is now made possible by a newly-available module that begins where the calculator manufacturer left off . . . and does lots more.

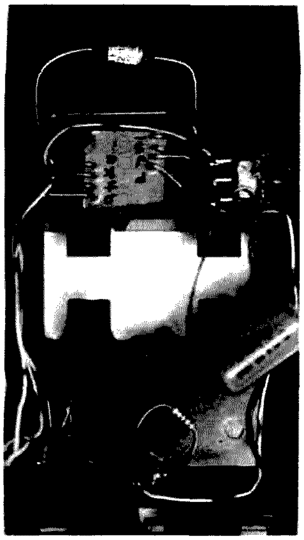


Fig. 1 shows the simple circuitry needed to transform your four-function, constant-add calculator into a *pièce de résistance*. So few parts are required that the whole addition almost invariably will fit completely inside the original case with room to spare. With simplicity like this, even the nicety of a printed circuit board is not worth the extra time and effort. The only external bits of evidence that your new instrument does more than calculate are the actuating switch, the test jack . . . and the smug look on your face when your friends see it do its stuff. You may, of course, want to exceed the bounds of the original case, but later.

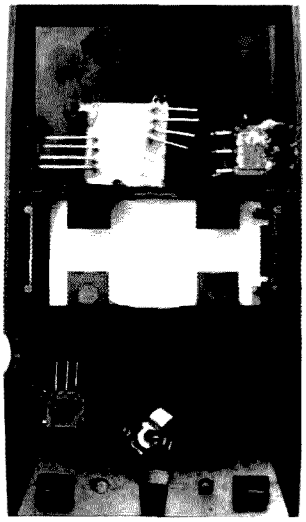
How It Works

The brain of this little circuit is Kaltek's RC-111 hybrid CMOS module with eight leads emerging from its 2×2×1 centimeter package. It utilizes the familiar time-constant principle to determine the value of the resistor under test. The calculator is caused to count and thus act as a timer to measure the time it takes for range capacitor Cr to charge through the unknown resistor, Rx. The counting function stops at a certain charge level on Cr as sensed by the high-impedance input (S) of the module.

Photo D. A 10-megohm resistor was soldered across the jack as an internal reference, and a 2-uF range capacitor (blurred) was temporarily enlisted to give a 20-second time constant for setting the counting speed. At top speed, the count was about 220 for the ten-megohm resistor, indicating that the range capacitor should be 1 microfarad and the timing pot slowed down for a count rate of 100,000-Ohms-per-count. The module lead identity is cast in the sides of the package; they were transcribed on the facing surface for clarity.

Photo C. The main fixtures—module, actuating switch, test jack, and count-rate pot—are stuck in the bottom of the TI-1025 case with hot-melt glue. This stuff is handy and can be cut off the stick and melted in place with your soldering iron. You don't need to buy the glue gun for the job.



The counting rate is adjusted by the combination of Rt and Ct, so what shows up when the display stops counting is a number equal to the value of Rx, with various numbers of decimal places determined by the size of Cr. Your personal intervention merely involves clearing the display and entering an initial "1" to count from, then flipping the actuating switch. Your calculator retains, unimpaired, all of the original functions it had, when the display is not running or when the test leads are removed to short the jack. If you have any parallel- or series-resistance calculations to make after the display shows the value of your unknown, you are immediately ready to make them on the keyboard.

Construction

There's really so little to do that the circuit diagram tells it better than words. About the only precaution is on behalf of the CMOS-based RC-111 module, which, although protected as well as functional requirements allow, should be handled so as to avoid any exposure to static electricity. That is, ground yourself and your (non-transformer) soldering iron before touching the module leads. Once it's in the circuit, it's rather safe (if wired as shown, of course).

For openers, wire the module separately as shown, with the leads uncut. Their functions are identified on the case. You need to start from some convenient known condition. For calibration accuracy, a 1% resistor should be chosen, somewhere around one megohm. For ease of handling the corrective arithmetic, use a 1-microfarad capacitor for Cr, of any tolerance. Chances are that you'll have to change or pad it later, any-

Photo E. The only things showing externally are the jack and switch . . . and your own look of satisfaction! The author plugged a photocell in the jack and used the freshly-built instrument as an enlarging exposure meter to make these prints. Only an initial test print was required to get the range.

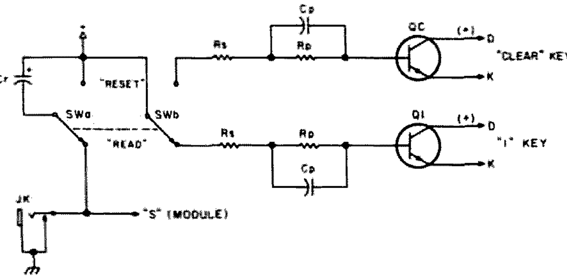


Fig. 2. Optional circuit to actuate CLEAR function, enter 1, and perform the READ function all from a DPDT switch.

Parts List for Fig. 2 (see text)

Rs—.5 to 1.5 megohm, ¼ W
Rp—10 to 22 megohm, ¼ W
Cp—.01 uF, ceramic, 10 V
QC,1—NPN silicon transistors, general purpose
SWa,b—DPDT toggle switch (replaces SPDT of Fig. 1)

how. The pot (Rt) should be at the high-resistance end of its span to begin with.

Now get intimate with your calculator. For the easiest trip, choose from the National Semiconductor Corporation's NOVUS 600 series or their private brand equivalents that now carpet the terrain like transistor radios ("Mathbox," for example). Some have fixed or switched-on decimal points. All have the necessary constant-add function, which means that if you enter a number and repeatedly punch the "ADD" key, the number will be added to itself in the display. Other brands with this function are also good contenders, but these are easy to find, cheap, and very cooperative. The earlier ones have an 18-DIP chip for the calculating, designated MM5736; later ones have the same characteristics, but the chip is buried under a plastic glob on the flip side of the display board.

Some have LED drivers, and some don't. That aspect doesn't matter. What does matter is how easily you can find and identify and polarize the leads from the CLEAR, 1, and ADD keys. The calculator can be a junk-box habitué, and many are by now for various reasons. If yours failed mechanically on the keyboard from bad key contacts, you still can use it for an ohmmeter and inject new life into the old box. For a DIP-cased MM5736 chip, the needed pin identifications are in Table 1.

The shared pin in Table 1 is coincidentally a result of the matrixing of the keyboard; all keys are shared, but you won't need the rest. Chances are if you are compelled to poke around looking for the needed ones, though, you'll find at least half the others first (in which case, if I didn't forewarn you, you might be non-plussed—minussed, even—to discover all these funny coincidences yourself).

If your machine isn't old enough to have pins, take a 10k-Ohm resistor and use it to jump the various keyboard leads you can spot, with a number entered in the display for you to watch the results on. Or, put your scope across the leads and poke the keyboard until the scope signal shorts. A standard ohmmeter used with calculator power off would do the same thing, but I hesitate to recommend putting its voltage, however low, on a dead section of the chip. The whole process only takes five or ten minutes with a resistor, and it's harmless. So try that method first, and as you identify the leads and determine their polarity from battery negative, mark everything down with a diagram to help you relocate the right ones later on.

Key	Pins	Called	Most-Positive	Remarks
ADD	1-3	D4-K3	1 (D4)	All "D" pins generate positive pulses to the K pins. ADD and CLEAR share pin 3 (K3).
1	4-17	K1-D2	17 (D2)	
CLEAR	2-3	D1-K3	2 (D1)	

Table 1. Pin identifications.

To recapitulate, at this stage you should have found your needed keyboard leads, identified their polarities, and have the module circuit wired and ready to connect to the calculator for temporary initial testing and calibration. With the power off, hook the module plus and minus leads to the calculator power points and set the module circuit switch to RESET, shorting the range capacitor. Now you're ready for the fun part, and you should make sure your battery is reasonably fresh, or else use an adapter. The MM5736 chip needs at least 6.5 volts to operate, but the module needs .5 volts more, so stay above 7.0 volts during testing.

Initial Testing and Calibration

Power up the calculator, clear the display, and enter a 1. Flip the module switch to READ and note that the display starts counting up from 1 and soon comes to a halt. You should then be able to enter more digits via the keyboard. Press CLEAR twice, enter 1 again, and flip the switch to RESET and then READ. Again the display should rack up about the same bunch of numbers.

So far, so good. Now you have proved that things are in working order and you can start shooting for the fastest counting rate your particular calculator chip can deliver. While alternately RESETing and READing the switch, twist your timing pot (Rt) towards minimum resistance to speed up the counting rate. You may get up to the magic limit of about 150 counts/second, but on average you'll hit around 60 before the display starts doing strange things like hesitating, stopping, showing EEEEEE, or otherwise not counting at a nice even clip. Back off on the pot setting and start over, babying up close to the forbidden point. Once you've found it, try timing the counts per second with a sweep second hand clock and record the results. You can do this most easily by leaving the switch at READ and putting a jumper across Cr, the range capacitor. That'll keep it running constantly.

So much for high speed; now you need to adjust your range capacitor so that the displayed number is a few counts higher than the value of the calibrating resistor... probably within a couple of decimal places. Say your Rx is one megohm and your count is 50 when it stopped running from a "1" start. That means you need to double your Cr value from its nominal one microfarad to extend the time to total 100 or more counts. Pick a combination of good capacitors for Cr that gets you there and a little beyond when paralleled with Cr. Run a few check counts, and then slow the count rate with the pot until it matches the calibrating resistor value. You should now have the best combination of high counting

speed and as much resolution as your chip can deliver.

For practical purposes, you are now ready to make a neat mess and pack it into the calculator-cum-ohmmeter. You may, however, want to consolidate your pile of add-on capacitors into the fewest number that will do the job. Try to stick with polystyrene or polyester caps to minimize dielectric absorption, which tends to throw off your first reading. Or else learn to accept the first reading and ignore any changes in a rapid retest of the same resistor. In any case, recheck your calibration once everthing is mounted permanently in the calculator case.

Locate the switch and test jack for your convenience; a thumb-actuatable position on the side of the case would work well for the switch, while the jack might be placed on the opposite side, consistent with the stuff already in your own calculator.

Error Sources

Over the 7.0-9.5-volt operating range you'll see a readout variation of about plus or minus 7%, which is quite adequate for most applications. If you wish to tighten up the precision, a zener diode with a bleed current of around 30-40 mA across the whole circuit—calculator and module—will hold variations to a couple of percent or less. This is rather tough on the battery, so an ac adapter should be considered, preferably with zener stiffening if you want to go all the way for precision. The slight error from the nature of the range capacitor dielectric has been mentioned; it's not big, but it's hard to avoid.

Real super capacitors carry a real super price tag; if you're that fussy, maybe you should send your unknown resistors to the National Bureau of Standards. Ceramics are compact and cute, but their capacity/voltage effects are impossible; forget them. If you intend to use large capacitance values for Cr in order to read low resistances, you should stick to tantalums and timing-grade types, if you can. Regular electrolytics will be quite hopeless for a good instrument. For 1000-Ohms-per-count, you'll need some 10-20 uF; for 100-Ohms-per-count, then about 100-200 uF would be required and your decade-matching problem would get a little sticky. At some level, you should best accept what your analog multimeter can deliver for the low resistance readings, to avoid fighting the uncertainties of large capacitors.

Additional Helps

Some additional circuitry can be incorporated to make your instrument more nearly a "hands-off" machine. That is, you can avoid having to clear and enter a digit into the display by doing it electronically when you actuate the RESET/READ switch. This refinement is shown in Fig. 2 and calls for a DPDT switch in place of the SPDT switch shown in Fig. 1. The extra pole is used to send a brief pulse to the CLEAR key when you RESET and another such pulse to the 1 key when you READ. The capacitors in the transistor base legs can be ceramic for compactness, but they and the resistors in series may require a little cut-and-try for best performance. The parallel resistors across the caps can be 10-22 megohms. The series resistors need to be around .5 megohms to 1.5 megohms, depending on your particular capacitor and transistor combinations.

The object is to inject a pulse of just sufficient duration to clear the display and enter 1 at any operating voltage without fail. If the pulse is too long, the key will hang up excessively and, especially, the 1 key pulse will subtract counting time from the ADD key function and cause a low readout on your unknown resistance. Too short a pulse will be more obvious; the display will fail to clear and/or will not inject a 1 for the module to count from.

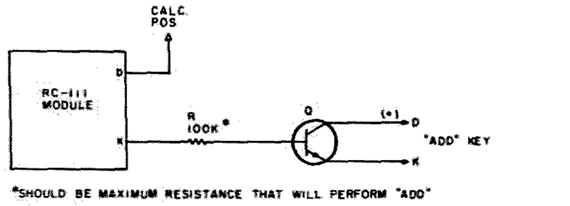

Fig. 3. Circuit for boosting module output for certain calculators (as needed).

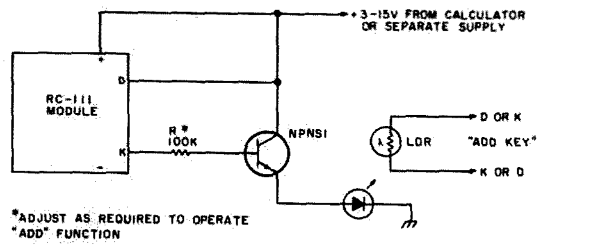

Fig. 4. Optically coupling module circuit to calculator.

Since the symptoms of erroneous choices are self-evident, it isn't too hard to land on the right combination. The series resistances should be on the high side to avoid ghosts in the display and excessive voltage on the transistor bases. The transistors can be just about any cheap silicon general-purpose units, the smaller the better. Once you have this circuit improvement squared away, the RESET/READ switch should do everything for you and prevent wear and tear on the fingertips.

Experimental Section

Other brands of calculators can be made to yield to this circuit scheme, but you may find that they have slightly different or perhaps more recalcitrant characteristics. Some appear to require a heavier current to actuate the keys, as evidenced by requiring a lower jumper resistor to do the job from the circuit side of the box. A boosted output for the module can be provided by a transistor in such a case, as shown in Fig. 3. In this case, the module D lead should be tied to the positive supply rail.

In calculators which have the necessary constant-add function performed by a third key (requiring, say, a CLEAR—1—ADD sequence followed by repeats on an EQUALS key, for instance), you still have the option of either entering the three initial keys and letting the module drive the EQUALS key or using the DPDT switch arrangement on the 1 and ADD, but leaving your finger to do the clearing. Again, the low-resistance keying problem might be present, which generally would result in three transistors being used for this arrangement.

Finally, if you have been intrigued by all the talk about opto-couplers, this project might be a useful place to start playing. Going back to the simple case of the module actuating the ADD key, you can produce this more exotically by shunting the key leads with a suitable light-dependent

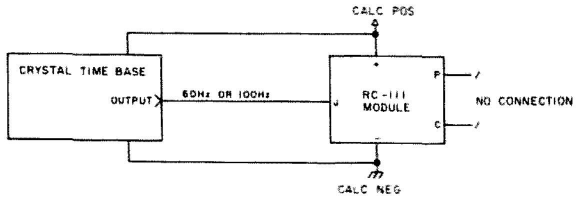

Fig. 5. Use of crystal timebase for high-precision ohmmeter and timer/stopwatch functions.

resistor (LDR) facing an LED operated by a transistor-boosted output from the RC-111 module as shown in Fig. 4. This scheme gives you a lot of potential design freedom, because the only necessary connection between the module circuit and the calculator can be a light beam. Consequently, if the gods and what-not are in your favor, you can operate the module on one battery (by itself, it only consumes a couple of milliamps, and only while counting) while the calculator operates on its own original supply, which can then include those situations beyond the 3-15-volt requirements of the module.

There are two precautions. First, the LDR has to act with reasonable speed in crossing from low resistance (to actuate the key) while illuminated by the LED to high resistance (for about an equal time) to let go of the key. Second, the LED has to be able to light the LDR sufficiently to effect the necessary low resistance, which means that it may require a pretty good-sized jolt of current to do the job. So, a satisfactory functional matching of LDR and LED is necessary and requires a little horsing around to get things just right.

Some LDRs are rather slow, and this might mean sacrificing some counting speed to incorporate this design. On the other hand, you may hit fat city and find that, for example, a fast and cheap photo-diode or photo-Darlington transistor will work just fine in your situation. Then you're home free. But you see why I entitled this part as an experimental section. As a hobbyist, you should be allowed to feel intrepid. On the other hand, I am obliged to state the disclaimers. I have to disclaim any responsibility for what you may do on your own hook. Fortunately, I have found so far that most calculators are very forgiving about all the rooting around in their guts.

Some Freebies

A number of non-ohmmeter possibilities may have become apparent by the time you have read this far. Yes, the module/calculator combo makes a pretty dandy and simple counter or timer or stopwatch, with or without the ohmmeter function. The timing will continue *ad nauseum* as long as module lead S is tied or switched to the positive supply rail and stop when it is on the negative rail. A second timing pot could be switched in to produce a timing speed more attuned to your needs.

Almost any calculator candidate should run fast enough to count by seconds; most will count by tenths, and some will make it to .01-second-per-count or beyond. For your own needs you might want to consider hundredths of minutes or even milli-hours or the like. Astronomers might even want to shoot for microsidereal-day time, in an extreme case. Although not crystal controlled, the precision is not bad with reasonable voltage regulation and can be set with an oscilloscope against multiples or submultiples of the 60-Hz line. For the calculator chips that can reach to 60 Hz or 100 Hz, one of the cute little boards that provides such with crystal control can be purchased for around $5.00 and run from most calculator power supplies. The output can be tied to the module as shown in Fig. 5, connected to the J lead while the P and C leads are left open.

Once you can measure Ohms digitally, you also can measure the ohmic relationships of other devices, of course. Therefore, this means that you can establish a relationship with light and temperature, to cite the most obvious examples. The aforementioned LDRs can be used to measure light, and at extremely low levels. So can a whole raft of other devices: photo-diodes, photo-transistors, and even plain LEDs. In these cases, the lower the light level, the higher the reading displayed, and if you have a big range capacitor, it might take minutes for the display to stop running if it is dutifully trying to count all the hundreds of megohms an LDR can reach at low light levels.

For this application I have found that a tiny 220-picofarad range capacitor worked about right for modest but useful counts when making enlargements in my darkroom. Because of the inverse light/count relationship, this combination is more properly a dark-meter, but that's beside the point. In effect, it reads out a number proportional to the right exposure . . . that's the bottom line in the photographic application. The LDR could optionally be connected to replace the timing pot (Rt) with a fixed combination of Cr and Rx chosen to time for a few seconds. In such a case you would get a reading that increased as the light intensity increased; however, in too-bright light, the calculator chip counting rate would be exceeded and the display would show funny results. With the LDR as Rx in the ohmmeter circuit, the excessive light intensity would register only your originally-entered 1 and would create less confusion.

A precaution about LDRs: As well as being a little slow, they have varying degrees of memory, so they don't immediately settle down on the first reading after a shift in light level. The fastest ones get there well enough to be extremely useful, but you would detect the discrepancy on a succession of readings. Thermistors are decidedly non-linear, and it takes some extra fooling around with the circuitry to get them to put out real temperature readings over a useful span. Ideally, you would fortify yourself with a calibration curve, or "normalize" the application.

If, for instance, you want to display a single photo-developer temperature digitally, and always use that temperature, the thermistor/range capacitor combination could be made to display "100" at the chosen temperature, from which you could empirically set acceptable limits from this value to suit the precision requirements for your needs.

Hams develop other situations for themselves in which a digital display of the results could be useful. An azimuth readout could be provided for an antenna, for example, by tying a suitable pot to the rotating antenna shaft as the Rx generator and scaling the display relationship to read out the number of degrees

representing the direction. Or, with a linear pot as the unknown, you could make a digital micrometer of sorts. The mind boggles at the prospects.

Perhaps the most immediately useful takeoff on the ohmmeter is the alternative of making the range capacitor the unknown and scaling with resistors in the Rx position to provide a few decades of readability. A megohm or two will give a display in microfarads to two decimal places. A commensurately longer string of resistors can enable you to reach to 100-picofarads-per-count and read microfarads on the same scale to too many decimal places to be of practical interest—and taking that much more time to count, as well.

The switching requirements to make a combined ohmmeter/capacimeter are not horrendous, but to do a really good job, you would want to consider a bigger case to accommodate range switching. If you have a dead-keyboard calculator to start with, perhaps try putting in a huge LED display in place of the usual small one. With commercial capacimeters selling for about ten times the cost of the Kaltek module, you can do almost as much (except for the teeny capacitances) and have the advantages of the digital ohmmeter in the bargain.

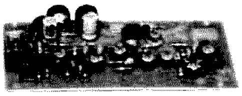
Conclusion

I could go on and on until the applications for the RC-111 module were limited by my imagination. But it seems fitting to leave off as above and tell you that the applications are limited by your imagination. In any event, this little device has a truly impressive cost-benefit ratio, and I'm confident that you'll flip over it.■

FAST SCAN *$249

A modular approach. . . for your own custom-designed ATV system. . . . Here's how

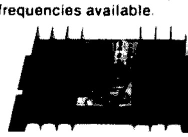
TXA5-4 ATV EXCITER/MODULATOR. $89 ppd



This wired and tested module is designed to drive the Motorola MHW-710 module in the PA5 10 watt linear amp. The crystal in the 100 mHz region keeps harmonics out of two meters for talk back. The video modulator is full 5 mHz for computer graphics and color. Requires 13.8 vdc reg @ 70 ma. Tuned with xtal on 439.25, 434.0, or 426.25 mHz. Provision for sync expanding. Two frequencies available.

PA5 10 WATT ATV POWER MODULE $89 ppd

The PA5 will put out 10 watts RMS power on the sync tips when driven with 80 mw by the TXA5 exciter. 50 ohms in and out, plus bandwidth for the whole band with good linearity for color and sound. Requires 13.8 vdc regulated @ 3 amps

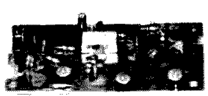


FMA5 AUDIO SUBCARRIER GENERATOR . . . . $29 ppd

Puts audio on with your camera video just as broadcast TV does at 4.5 mHz. Puts out up to 1 v p-p to drive the TXA5 or VM-2, 3, or 4 modulators. Requires low Z mic (150 to 600 ohms), and + 12 to 18 vdc @ 25 ma. Works with any xmtr with 5 mHz video bandwidth

TVC-2 ATV DOWNCONVERTER. . . . $55 ppd

Stripline MRF901 (1.7 db NF) preamp and double balanced mixer module digs out the weak ones but resists intermods and overload. Connects between uhf antenna and TV set tuned to channel 2 or 3. Varicap tunes 420 to 450 mHz. Requires + 12 to 18 vdc @ 20 ma. Super sensitive TVC-2L with NE64535 preamp (9db NF) stage . . $69 ppd.



***TXA5, PA5, FMA5 and TVC Basic Module Pkg.**

Call or write for our complete list of specifications, station set-up diagrams, and optional accessories which include antennas, modulators, detectors, test generators, cameras, etc. **WE ARE A FULL-LINE SUPPLIER OF ALL YOUR ATV NEEDS.**

The places to buy ARCO Solar™ Power Systems are popping up everywhere.

For some very sound reasons. Not all solar electric systems are created equal. ARCO Solar products offer all the features that add up to superior performance and increased value. Features like design, construction, warranty, accessories and service. Those who know what dependable, stand-alone power can do for their communications equipment, know how important these features are.

And now, there are 2,500 dealers across the United States and Canada offering ARCO Solar power systems. For the name of the dealer nearest you, contact one of our regional distributors:

Scanning with the IC-280

How many times have you seen a nifty circuit that would expand the capability of your operation only to be stopped cold by the thought of drilling holes or otherwise performing cosmetic surgery on your shiny new rig just to mount controls for the additional function? Here is a scanner that uses existing switches, costs about $25 maximum, and mounts inside the control head.

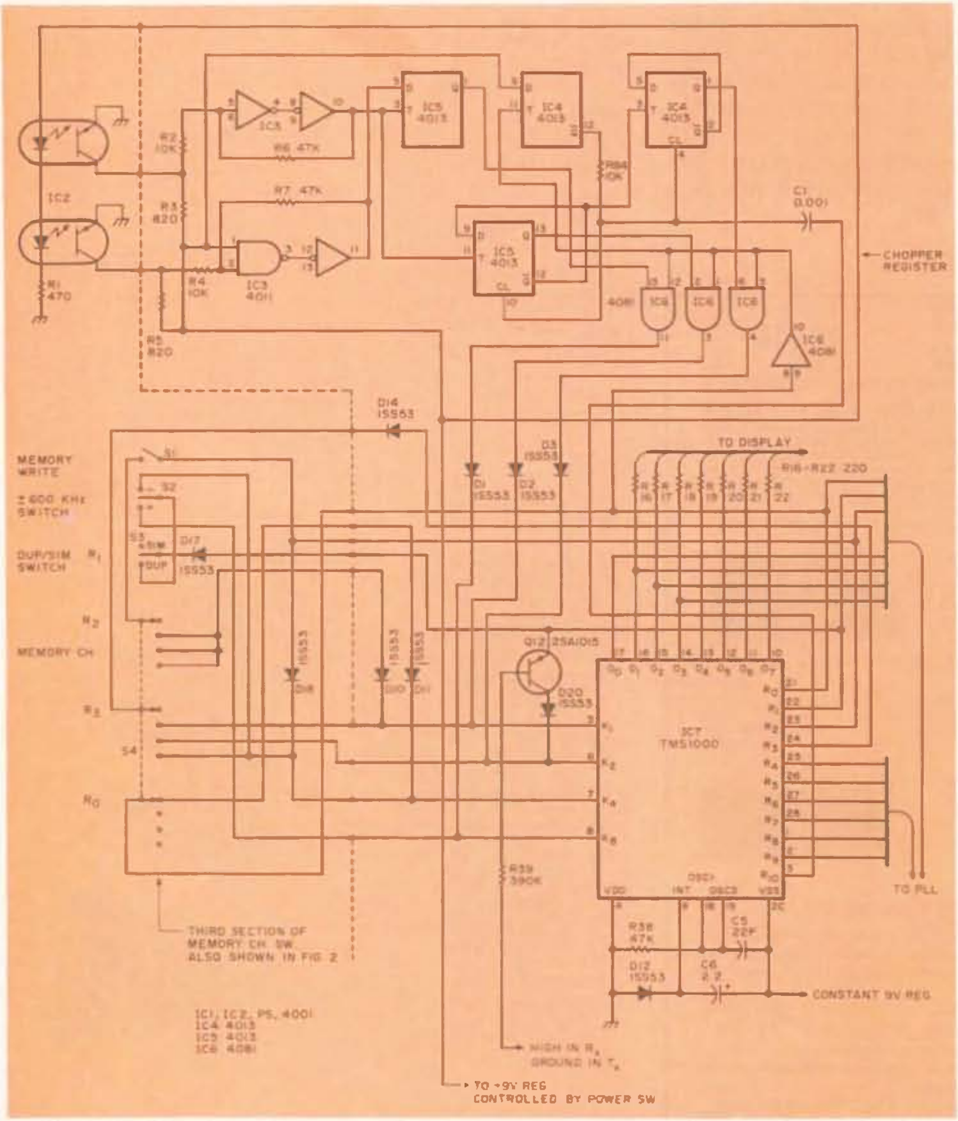

Fig. 1. IC-280 schematic diagram showing microprocessor and control input circuitry.

Two-meter transceivers as a class have been trending towards the low current drain of CMOS control circuitry, notably synthesizers and attendant display circuits with external control capability. The earliest example of this type of transceiver in the Icom line was the IC-22S which, for the first time, offered hams the ability to interface their rigs with a wide variety of hardware. Since then, several advances have been made, the latest of which incorporates a microprocessor into the control function.

Before proceeding further, one point should be emphasized. The microprocessor in the IC-280's control head resembles less a hobbyist's computer system (8080, 6800, Z80, etc.) and more the type found in a calculator. The chip is from Texas Instruments' TMS 1000 series of microprocessors which have all RAM and ROM in the same package and cannot access external memory of any kind. The ROM is mask-programmed at the factory and cannot be changed.

Nevertheless, it offers enormous flexibility (from the designer's point of view) in that it can be tailored for any type of control function in any type of system that can be imagined.

Flexible for the engineer but pretty well set for the user, right? Well, not quite.

The secret of enhancing the control capability of such a system lies in the realization that while the microprocessor is programmed for a limited number of control functions, these same functions need not be accessed via mechanical switches but electronically instead, upon command of other signals within the transceiver. In short, it is very easy to cause the radio to tell itself what to do.

Strobe/Function	Data Input Lines K1	K2	K4	K8
When dial is selected and RO is positive	N/C	N/C	High	N/C
R1 is the sim/dup strobe. When it is high and the dup. function switches are set, the following occurs	N/C	High if dup and in Tx	High if −600 kHz	High if +600 kHz
With memory-write switch depressed and R2 high	High	N/C	High regardless of memory write	N/C
If R3 is high and the memory-channel switch is set as follows:	High if Ch. 1	High if Ch. 2	High if Ch. 3	N/C

Table 1. Input data codes for microprocessor IC-7 in the IC-280 control head.

Theory of Operation

To understand how the scanner works, it is necessary to describe how data gets entered into the microprocessor.

The type of input used is called a scanning matrix. Basically, this means that there are just four lines (K_1, K_2, K_4, K_8) where information will go into the chip. However, due to internal circuits, the data input lines accept only certain types of information at certain times. These times coincide with a high R strobe, only one of which is positive at any given time.

For instance, of the four strobe lines we are interested in (R_0-R_3) for data input, we will assume that the R_0 strobe has just gone high, or positive. Strobes R_1-R_3 then are at a low, or ground potential. For the period of time that R_0 is high, the data lines K_1, K_2, K_4, and K_8 are interested only in data from the optical chopper register. This data will cause the frequency to increase, decrease, or remain unchanged and is updated at the strobe rate of about 125 pps (pulses per second).

Referring to the IC-280 control-head schematic in Fig. 1, it can be seen that the data lines are physically connected to a variety of switches and circuits. The reason that data from the chopper register is not garbled by these other components is that the common contact of each switch is connected to the strobe appropriate to its function. When the R_0 line is high and all other strobes are low, each low strobe is prevented from sinking current or pulling down voltage on the lines by means of a blocking diode.

When the R_1 line goes high, only data corresponding to that strobe is generated. Next, the R_1 strobe goes low and R_2 goes high, and so on. The function of each line in the matrix is listed in Table 1.

The scanner-module schematic is shown in Fig. 2. The switch section at the bottom of the diagram is the last section of the channel-select switch (see Fig. 1). The common contact normally connected to the R_0 strobe is now connected to the power switch through a resistor, R29. This allows the use of the switch section to select the dial mode in either the D or CH 3 positions by using analog switch S1 to perform the previous function of the channel switch. Thus, when the D position is selected, the transceiver operates normally.

However, with suitable modifications to the other two sections of the channel switch in the CH 3 position, the voltage now available from the last section in the CH 3 position is used to turn on analog switch S2 in the scanner, allowing pulses to pass through it. Analog switch S3 is normally turned on in the receive mode and will allow pulses from analog switch S2 to go to the chopper circuit. S3 is turned off in transmit, preventing scanning.

In the scanning position, a positive voltage is connected to pin 4, IC5 in the control head, which is the RESET input for the up/down flip-flop in the optical chopper circuit. Since the voltage causes the Q output to be forced low, the microprocessor always counts down.

To make the scanner count up, the SET line must receive the positive voltage while the RESET line is grounded. However, the scanner's performance is the same in either mode and it is easier to wire the IC to count down.

When the 280 receives a signal, a dc voltage imposed on the audio line is transmitted from the squelch circuit to the base of Q11, causing its collector to be grounded. The receive LED whose cathode is connected to the collector of Q11 is then lit. The collector of Q11 is also connected to terminal 11 of the scanner which in turn is connected to pin 12 of IC3, the input on a NAND gate. If pin 13, the other input to the NAND gate, is high, then the output on pin 11 will go to ground. A negative spike is then generated by C_4 and R_7 and is used to trip the monostable multivibrator which consists of two NOR gates from IC1 and C5 and R8, whose time constant will roughly determine the length of pause on an occupied channel. The values shown will yield about 9 seconds. R8 can be decreased to 50k Ohms to generate shorter pause times.

When the monostable is tripped, pin 10 of IC1 goes to ground, which pulls down the control line of analog switch S2 through D4. This action stops the pulses going to the chopper circuit, and the transceiver will stay on the channel until the one-shot resets.

The monostable circuit will not respond to further trip pulses on its input after the original spike so that the practical result is for the scanner to stop for a fixed length of time on an occupied channel no matter how many times the squelch is broken.

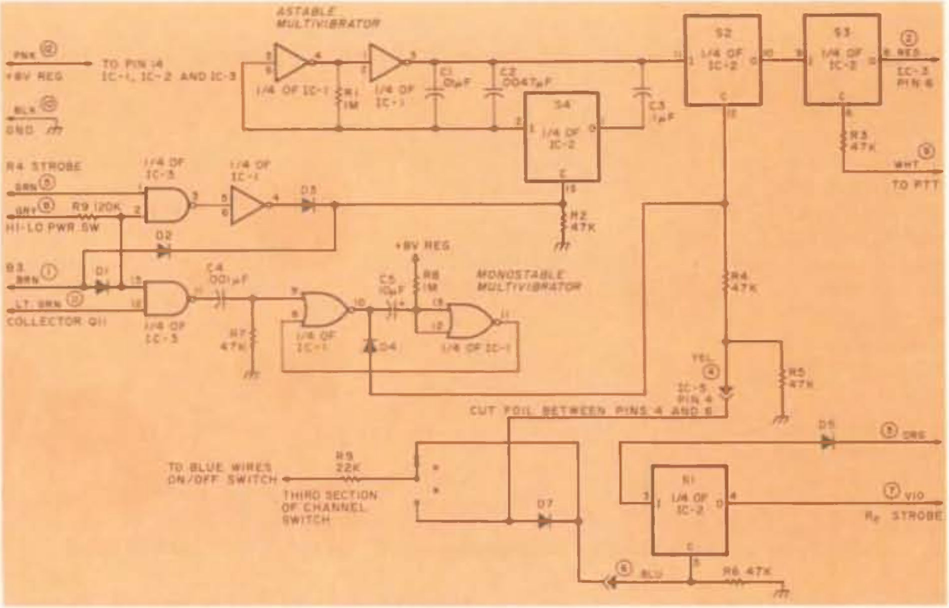

Fig. 2. Scanner module schematic.

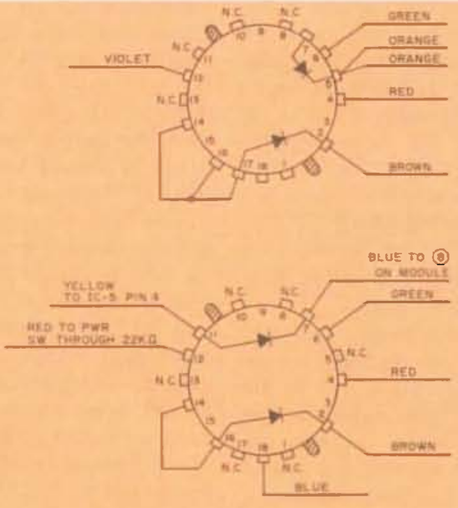


1-4	No change.
5	Remove cathode of diode. Remove 2 orange wires and splice with orange wire from module. Leave this tab unconnected.
6	No change.
7	Remove anode of diode (its cathode was removed from tab 5). Install cathode of new diode and blue wire from module.
8-10	No change.
11	Connect the yellow 6" wire (not from the module) and anode of the diode whose cathode was connected to tab #7.
12	Remove violet wire and splice to violet wire from module. Install the 3" red wire (goes to power switch through 22k).
13-15	No change.
16	Remove anode of diode connected to tab 17 and connect it to this tab. This will leave tab 17 unconnected.
17	See tab 16.
18	No change.

Fig. 3. Channel switch pictorial and modification instructions (rear view).

The astable multivibrator, whose output is fed to analog switch S2, has two speeds selected by analog switch S4. When S4 is on, more capacitance is connected in parallel with C2 and C3, lengthening the time constant and lowering the output repetition rate. When S4 is off, the repetition rate increases.

The reason for the two pulse rates is that in the 146-148-MHz portion of the band, the set tunes in 15-kHz steps, and the 143-145.99-MHz portion tunes in 5-kHz increments. To keep the time spent in the lower portion of the band more or less equal to that spent in the upper portion, the scan rate must increase. The fastest scan rate is used if one is not interested in the lower portion of the band, a more moderate speed is used to detect occupied frequencies below 146 MHz, and 146-148 MHz are always scanned at the same rate.

If one wishes to receive signals in the 143-145.99-MHz range, two contradictory problems are apparent. First, if the scan rate is too fast, the scanner will not reliably stop on frequency—if it stops at all. If the rate is slow enough to stop reliably, the unit will spend a much greater period of time in a portion of the band which is relatively unused. The solution is to connect NAND gates, one of which is used as an inverter, to terminals 5 and 8 of the scanner and turn analog switch S4 on or off, depending on the state of the inputs.

Terminal 5 of the module is connected to the R4 line which is low when the kHz digit is 5 and high when the digit is 0. If the Hi/Lo power button is pushed in, terminal 8 is high. This means that analog switch S4 will be off when the kHz digit is 5 and the astable will have a high repetition rate. When the kHz digit is 0, the astable will take a longer time to change state. Therefore, a minimum time is spent on frequencies ending in 5 kHz and a maximum time on all others when below 146 MHz.

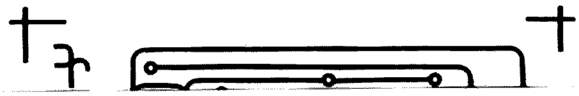
If terminal 8 is grounded (Hi/Lo button out), the scanner will be in the high-scan rate all the time unless terminal 1 goes high and turns on analog switch S4 through D2, slowing the scan rate. Terminal 1 is connected to the B_1 line (R_1 line from IC7) which goes high from 146 MHz to 148.11 MHz. The connection between pins 2 and 13 of IC3 on the module ensures that if terminal 8 is grounded, squelch breaks will not stop the scanner below 146 MHz, but will pause appropriately above 146 MHz.

Construction

Construction of the single-sided PC board is rather straightforward, and the foil layout is shown in Fig. 4. Wire color is specified in the schematic in Fig. 2, and component layout in Fig. 5. Tolerances are not critical; however, the components specified in the parts list fit the PC board. Since the

module is installed component side down, hookup wires should come out on the component side of the

and be careful not to strip the heads of the screws, which are generally quite



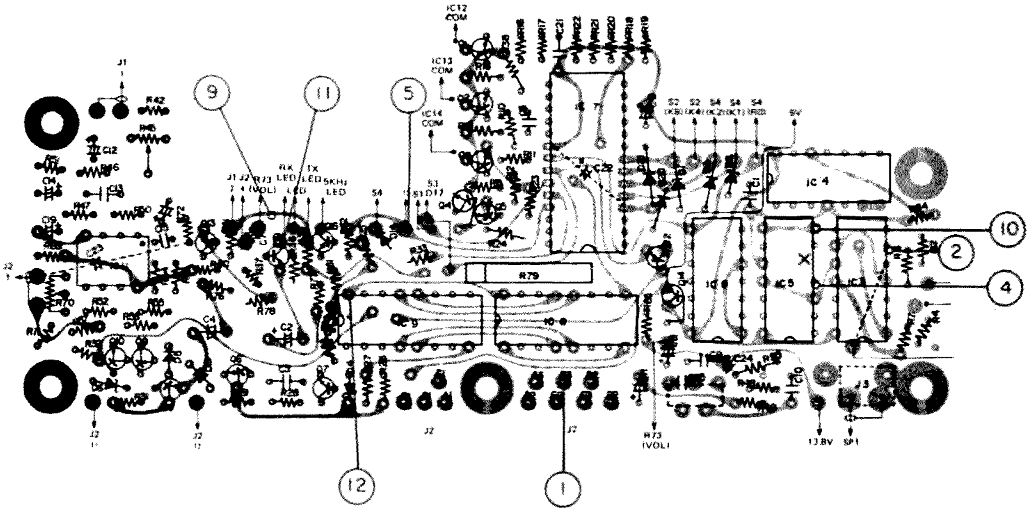


Fig. 6. Microprocessor and control board modifications location.

the leads of the CMOS IC in the head and also the tab on the memory-channel switch which has the yellow wire connected—it may be shorting to the metal frame.

To activate the scanner, select position 3 on the memory-channel switch. Do not be alarmed if nothing happens at first, but after about 10 seconds the digits will start counting down.

If the Hi/Lo power button is OUT, the scanner will pause again after changing from 146.00 MHz to 145.995 MHz whether or not a signal is received. After the pause, it should start counting rapidly downward until reaching 148.11 MHz, where it will count at a much slower rate.

When the Hi/Lo button is OUT and the displayed frequency is below 146.00 MHz and after the initial pause, a squelch break will not stop the scanner.

When the Hi/Lo button is IN, a squelch break (accompanied by the lighting of the Receive LED) should stop the scanner both above and below the 146.00-MHz boundary.

If these conditions cannot be obtained, check the input gate to the monostable on the module and also see if the cathode of scanner should always stop, thus preventing unwanted interference to others.

If a signal generator is available, hook it up to the antenna connector of the 280 and check to see that the scanner will stop on the right frequency. This check can also be performed using off-the-air signals if their frequency is known. If the scanner stops too late, increase the value of C3 by .001 uF to .005 uF.

Here are some ways the scanner may be used.

If the scanner pauses on a frequency of immediate interest, select position D on the memory-channel switch. This will be the same frequency as in the scanner position. Be sure to select the proper mode of duplex or simplex before transmitting.

If the scanner pauses on a frequency of less immediate interest, select either position 1 or 2 on the memory-channel switch and press the memory button to store the frequency. Select position 3 to resume scanning.

If a signal is received above 146.000 MHz and is not on the 15/30 kHz band plan, the scanner will pause will be quite readable. However, before transmitting the transceiver-tuning increments should be changed to 5-kHz steps according to the supplemental operator's sheet enclosed with the IC-280 in order to obtain the correct operating frequency.

Summary

With a few hours time and $10 to $25 invested, depending on where the parts are obtained, a reliable and simple-to-operate scanner can be added to the IC-280 without drilling holes or otherwise destroying the front panel. To date, seven scanners have been built using the above data and have been working with no problems.

For those who elect not to make the PC board, an assembled and tested module may be obtained by sending me a check or money order for $25. Etched and drilled PC boards only are available for $15.

Brief technical questions on the scanner can be answered only if you send me an SASE.

I would like to acknowledge the invaluable assistance given me by Allen

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 8

what to do about it, and lodging official complaints is not the answer. We've been that route for years.

The best solution to a nagging problem like this is to attack. Let's get organized and see what we can do to drive the dreaded dragon off our ham bands. If we work together, we can do it. And, yes, I'm suggesting some deliberate interference. Sauce for the goose.

Despite a lot of science fiction baloney about the woodpecker signals being used for behavior modification, all it is is long-range radar. The only behavior modified is the DX operators who start climbing the walls.

Okay, it's radar. Those of you who have an inkling of how radar works know the answer to the problem already. It's simple. If you want to screw up a radar signal, all you have to do is send a return signal on its frequency which blocks out the echos. Hams, from the earliest woodpecker days, have been driving the monster off their bands by getting on the frequency and sending properly spaced dots back. The screen somewhere in Russia blanks out and the operators utter some Russian oaths and change the frequency to get rid of the interference.

Now, if you chaps would get together into some networks to spot and erase this blight, we could get Ivan off our ham bands for good. You need a keyer which can be adjusted to send back pulses in between the woodpecker ticks.

There are a number of these pests around Russia, so you may have your hands full for a while. With persistence, I think they will stay out of our bands and go elsewhere for their radar work.

Or you can look on the bright side of things as you gnash your teeth over the noise. There is a good deal of evidence that the very high power transmitters being used for this work are having an effect upon the people immediately in its path. Indeed, one of the major woodpecker transmitter sites is just across the border from Finland and the incidence of cancer in the nearby Finnish town is reported to be exceptionally high. At this distance, *all* we get *is* apoplexy.

THE DANNALS DEAL

To say that I'm disappointed in a bunch of readers is to understate the case. I've gotten a lot of flack for my strong support of Dannals for the new general manager of the League and I think this needs to be brought out into the open.

Now look here... I think that some loyalty to the president of the League is in order and I don't want any more of those letters telling me that good old Harry is a pompous fathead. Harry and his father before him have been ARRL directors. Could you ask for any more loyalty than that?

And if you're worried about your League getting into trouble, just remember that Harry is already retiring from his lifetime of work as a union steward, so a couple of years as general manager of the League isn't going to make a lot of difference. Isn't it about time that a loyal supporter like that had a chance to get a decent salary for a year or two... and an unlimited expense account? Not to mention a very generous retirement from the League in a few years. That retirement pay plus his first retirement pay should allow Harry to go on as many DXpeditions as he wants without any further worry about money. It's only a few bucks out of your pocket, so why be chintzy?

Remember that amateur radio is in the doldrums right now. It's not the worst doldrums we've had... those were back in 1964-69... but they're pretty dol. Thus it really isn't going to make a big difference what the ARRL does for a while, so why get exercised? I say give Harry his due and stop all the beefing.

It is hard to stop the rumor mill, but I really don't put any credence in the gossip that Harry will be moving HQ to New York so it will be closer to his home. Of course, that would be a bit closer to Washington, where it really should be... but not close enough. Yes, I know that they don't need that huge building any more and that it is a bear as far as heating goes. But remember that the building didn't cost the League much since it was paid for by member building fund donations. With the staff cutbacks, they could make do with a lot smaller HQ building, or perhaps Harry will rent part of the building out to economize.

So let's not hear any more of this heresy and bad-mouthing of Harry, okay? Some of the things he's done have given the impression that he doesn't have both oars in the water, but that may be because you don't have all of the facts. Take heart and remember that even if Harry turns out to be as inept as Baldwin has appeared, the League will still survive. Not to worry.

ARRL ATTACKED

Those few of us who are still reading *HR* were aghast at the February vicious attack against the ARRL in the editorial. What is the world coming to? This would never have happened under the guidance of good old Jim Fisk, who was able to stomach anything the ARRL did.

Ham Radio magazine, which has been dropping steadily in ad support, had some corking good articles in February... too bad if you missed them *and* the ARRL attack. For instance, there was a pip of an article on how to use the HP-34C computer to design Pi-L matching networks, something which I'm sure has plagued all of us. Those pages of charts will be of incalculable value to thousands of hams who prefer to design their own matching networks and put them in place of the factory-built circuits in our sideband rigs.

Another spell-binder was a 7½-page article on the systematic design of crystal ladder filters. I'll bet they thought I'd forgotten all that calculus I was crammed with 40 years ago in college... well, here's where I could finally get it out and use it. You can bet that hams will be quoting that article for several years to come.

With the thermometer outside my window hovering at −10°, I read with amusement their state-of-the-art rotator article... using a rope going through two holes in the house to the beam. The two rope holes would let out enough heat to pay for a rotator in one winter here.

Well, I'm sure we're all glad to see *HR* hanging in there... even after losing both *Ham Horizons* and *Ham Radio Report*.

BUILDING

One of the ways in which radio amateurs have been of value to the country down through the years has been in their designing and building of new equipment. It's been a while since I've polled the *73* readers to see what percentage are into building, but the last poll showed that 80% had built at least one home construction project during the previous year.

The high percentage of ads for parts in *73* indicates that you readers are still building today. I don't think there is any other magazine with more ads for parts. Building is one of the more fun things to do in our hobby, so I'd like to do all I can to encourage more of it.

You know, it doesn't take a lot of technical knowledge to get started building. Once you get into it, you find that you are learning every day. It's a great fun way to learn the technical end of things... learn by doing. Then, when you get on the air, you have something real to talk about. You can beef over the problems you had in getting something to work, knowing that the chap on the other end is eating his heart out that he doesn't have a similar story to swap because he has bought *everything* he is using.

To help get more hams into building, I'm asking that everyone who has designed and built something unique write it up and send in the article. It's your responsibility to encourage more hams to build, and only a wealth of interesting projects will do this. Writing the articles is up to you. I'll publish them.

When I started *73*, it was with the idea of promoting ham building. Down through the years, *73* has always been the builder's magazine. We have used the space *QST* wastes on those endless activity reports to publish articles and more articles, a good percentage of

them on small construction projects which can be done in a weekend. Now, with *HR* rapidly fading away, we'll be running a few more of the back-breaking type of construction projects for which they were justly famous. We don't want them to stop just because *HR* is fading away.

Hams are builders. The more construction projects you send in for us to publish, the more you'll get in *73*. I would like to see articles on all aspects...simple projects and engineering masterpieces. I'd like to see 'em on digital circuits, gadgets for the home, for the car, antennas, tuners, automatic identifiers, new slow-scan circuits, color slow scan, and so on. We are perhaps five hundred articles behind on what I would like to see in RTTY developments.

There are some small groups working on ever more exciting repeater networking systems. Let's see articles on these which will spur other groups to get into the game. Let's see articles on the networking circuits. I don't know if you know about it, but there are at least a couple of ham UHF networks which connect virtually all of the western part of the country together. You can use an HT in San Diego and talk to El Paso or up to Oregon, all without interrupting local repeater operations along the way.

No one has figured out how to get from the Rockies east with these nets so far. The short hops in the flatlands have temporarily stopped the spread of these systems. Perhaps we can have some ideas on that...and more construction projects.

You design it, build it, and write about it...and I'll publish it, getting thousands of hams to build your circuits.

GOOD ARRL NEWS!

Just when I begin to get discouraged over the slowness of the League to react to technology and other changes, something interesting comes along. In this case, there is a report in a well-known DX bulletin to the effect that some badly needed changes in DX contest rules have been made.

The piece reports that the ARRL contest advisory committee in a vote of 8 to 3 has decided to modify the operating periods of both the CW and the phone DX contests to allow two additional hours of operation for both the first and second district stations. They noted that during the last few years the East Coast has come very close to losing its dominance in this event and the committee felt that this rule change would ensure that the traditions of the past are preserved. Bravo!

Anyone with comments pro or con should contact *QST* about this. I think we should continue to look to the League to preserve past traditions and look to *73* to preserve traditions yet to come.

FAVORS

Most of us have read some of the reports from the FCC on the trial and conviction of one of their licensing people for selling ham licenses. A lot of hams got furious when they heard about that.

After talking with some of the people who were intimately involved, a rather different story from the official version is told. It appears that there has been a good deal of cover-up of actions by higher FCC people who seem to have started the whole mess.

I've read the official reports and got the impression that this chap Zigler had been selling ham licenses and got caught, and that there were just a few bad hams involved.

This is reported to have gotten started when Prose Walker, who was the chief of the ham division of the FCC, started asking Zigler to do some "favors" for friends of his—upgrading of licenses, special calls. Zigler apparently got fed up with this after a while and told some of his close ham friends about the situation and asked if *they* had any special cases who might need a favor, as long as he was doing favors. No money was involved with any of this. One chap I talked with swears he was in the room with Zigler when Walker called with a request for five more friends of his to get favors.

Things mushroomed, with the final count being 843 favors granted by Zigler. That's more than a few. Eventually the word got around and Zigler's friends began getting cash offers for upgrading of their tickets. Then, after a while, some of the friends were sending Zigler cash. It's tough to send back unaccounted-for cash.

Someone finally blew the whistle. Zigler was convicted and put in prison for a few days. The FCC came out of it fairly clean, and a few of the favor recipients lost their tickets. Just a few, not 843.

This is still grinding along through the courts on some level, so some day we may get the facts and be able to put all this into perspective. The people involved use the term "favors" rather than bribery. This seems more applicable in this case. I understand, too, that Zigler was quite upset by the pressures he was under to do these favors for Walker and I suspect that the favors for friends were more in retaliation for being forced to do what he considered wrong than as an enterprise in itself. All agree that Zigler was one of the nicest guys you could ever want to meet and that he was a victim, not a criminal.

Well, that's the story. I'm open for any further information, pro or con, as this develops.

Some of the victims of this disaster are asking what the real difference is between someone who has been upgraded as a favor and the chap who has spent one day with Bash in his high-pressure memorization course which teaches you all of the test answers word for word. The end result is about the same: a higher grade license with no knowledge necessary.

The real misery comes later when these people get on the air and can't let their fellow amateurs know that they don't know anything. That's when we start finding bad language and disruptive operating.

I can't in any way defend what these chaps claim Walker got started...or Zigler continuing it. But is it fair to crucify Zigler and let Bash keep going?

SMITH CHARTS

That's right, Dick Smith of Dick Smith Electronics in Australia is charting a trip around the world via helicopter. And, yes, of course he'll have a ham rig aboard, working 20-40-80 meters as he flies.

The trip, which is scheduled to start in August, 1982, will be a solo flight, with most hops in the 200-400-mile ranges. It will start from Dallas and run up the east coast, across to Greenland, Iceland, the Faroes, down across Europe, down by Jordan and Egypt, across Saudi Arabia, Pakistan, up to New Delhi and Katmandu, down to Calcutta and Rangoon, and on down Australia to Sydney...home. Then he'll head back up through eastern Asia across the Philippines, Japan, and across the northern Pacific via a couple of shipboard refueling stops to Adak in Alaska, down to Anchorage, Seattle, and to Dallas. He's expecting to end the trip in early 1983...the first solo helicopter flight around the world.

Working him as he is flying will be fun, but I do hope he will plan some time on the ground to get on the air and give us DX fanatics contacts with the 30 countries he will be visiting along the way.

As the trip draws near, we'll

Australia's Dick Smith VK2ZIP.

try to have a lot of information on it for you.

READER RESPONSES

There are some questions about *73* on the reader response cards and every so often we get reports from the firm which processes these for us. I think you may find some of the news interesting.

For instance, the latest replies, sampling about 5% of the readers, gives our readers an average income of $26,400 per year. Surprisingly, perhaps, 31% are making over $30,000 per year. Affluent group, really. That's up from 21% a year ago.

We asked how much you spent last year on ham gear and the average was $750. That's the average! When we apply that to the entire readership of *73*, we find that you are spending nearly $8,000,000 per *month* on ham equipment. Now that's just you *73* readers, mind you, not the average ham. Indeed, there is a good reason to believe that our group represents about 70% of the total buying of ham gear. That's higher that we expected.

Manufacturers looking for new products which will interest hams should note that 13.1% of the readers are actually active on RTTY today and 48.9% say they are not on RTTY, but are interested in getting on RTTY. That comes to around 60,000 *73* readers who have expressed an interest in RTTY. That's a gold mine if I ever saw one.

With the increased circulation of recent months, and going by the reported readers per copy of the magazine, over 125,000 hams are reading *73* every month. At $3.00 per copy, there is a lot of pass-along readership, but the pass-alongees are mostly active buying hams, not retired old-timers on pensions.

Speaking of gold mines, 80.5% of the readers want more articles on satellite television. I honestly expected to run into the usual resistance to new ideas with this and am pleased that everyone is hot to trot. You know, it is only a matter of time (and not much) before hams start getting much more into satellite communications. The time is just about here for that.

From 73 MAGAZINE

THE MOST UP-TO-DATE REPEATER ATLAS AVAILABLE!

WORLD Repeater ATLAS

INCLUDES:

- LISTINGS BY STATE AND COUNTRY
- LISTINGS BY FREQUENCY
- MAPS FOR EACH STATE
- 28 MHZ THROUGH 1296 MHZ
- PERFECT FOR MOBILING

• WORLD REPEATER ATLAS—BK7315—Completely updated, over 230 pages of repeater listings are indexed by location and frequency. More than 50 maps pinpoint 2000 repeater locations throughout the USA. Foreign listings include Europe, the Middle East, South America and Africa. $4.95.

IN STOCK AND READY TO SHIP

*Use the order card on the Reader Service page of this magazine or itemize your order on a separate piece of paper and mail to: 73 Radio Bookshop • Peterborough NH 03458. Be sure to include check or detailed credit card information. No C.O.D. orders accepted. Add $1.50 handling charge for the first book; $1.00 for each additional book. Questions regarding your order? Please write to Customer Service at the above address. Please allow 4-6 weeks for delivery.

WALKMAN TALKMAN

About three years ago, Sony came up with one of their usual brilliant ideas... the Walkman. This was a tiny audio cassette player which could be worn on the belt and used with a startlingly new type of lightweight stereo earphone system to make it possible to enjoy truly high-fidelity sound reproduction.

Having been a manufacturer in the hi-fi business back in its early days and thus knowing what is involved in such reproduction, seldom heard with home systems which are affordable, I was astounded when I first heard the Walkman player. It was great for walks and even for skiing. Of course, by the time I loaded up for skiing with the Walkman, some tapes, and an HT, my pockets were so full of expensive electronics that I didn't dare fall down.

As tiny as the first Walkman from Sony was, a couple years later they surpassed themselves with an even smaller player... almost the size of the cassettes, only a bit thicker. This came out at about the time that the market was being flooded with knock-offs of the original Walkman made in Hong Kong and Taiwan.

If you have never listened to the sound from a Walkman, you should take the opportunity the next time you see a friend with one.

Okay, now on to the Talkman... not by Sony, but being made by an old Japanese friend of two-meter hams... Standard. I ran into an ad for this unit in the latest JS&A catalog. Joe Sugarman, who, by the way, is a ham, has built up quite a reputation for state-of-the-art men's toys, so I wasn't surprised to find this new gadget appearing first in his catalog.

The Talkman is a 50-MHz transceiver which you wear on your belt and which comes with a headphone-microphone set. It is designed for use by two people who want to be able to talk despite local noise or moderate separation. The transmitter is voice actuated, so you don't have to flick any switches. The sound is excellent quality, and there are a minimum of controls and adjustments so that anyone can put it on and use it.

This is just what Sherry and I have been looking for to use in the Dodge van. It is so noisy in the van that normal conversation is almost impossible, even when she is in the front seat. As soon as she heads for the seats in the middle or the lounge in the back, we've always had to scream to be heard. The Talkman is perfect for this type of use.

The Talkman is also great for things like skiing lessons where you want to talk to someone without having to yell a hundred yards or so. Or for talking with someone on top of the tower making adjustments while you are in the shack tuning up. The chap on the top of the tower does not need to hold an HT in one hand and the tower with the other. We lose a lot of hams that way.

Have you ever gnashed your teeth in frustration while waiting for your wife to come to an arranged meeting spot in a shopping mall? With a portable typewriter I could have written an encyclopedia just in waiting time. Now, with the Talkman... I'm able to find out just which of the toy stores has grabbed her and is holding her for ransom. Grandchildren, you know.

They're a lot lighter and easier to use for short-range communications than HTs, even if both people wanting to talk have tickets. No license required for these low-powered 50-MHz sets ... and the antenna is built into the headphone wires, so you don't even poke out eyes.

Sherry, who is into ballooning (just went down for her instructor's ticket), will find the sets great for balloon-to-ground communications. It's very handy to let the ground crew know where you're planning to land. Sherry got hooked on balloons when we went down to Florida about five years ago for a two-meter balloon-to-balloon operation. Now she has her own.

I've often wondered why Standard didn't keep up with the US two-meter market. They were one of the first and foremost in the field here, but then got behind when the Icom synthesized rigs came out. I still see some great looking Standard ham gear in the Japanese magazines, but no sign of US models being made. I'm still getting good use from my old Standard HTs.

Detect Killer Tornadoes

—use an ordinary TV set

Editor's Note: This article presents a controversial method for detecting tornadoes. *73 Magazine* urges you, the reader, to consider ALL practical methods of storm detection. We endorse no particular procedure but do encourage experimentation with the Weller Method and other promising ideas. We would like to hear from any group or individual who has automated the Weller Method or used it in conjunction with an amateur radio network. For more information, see *Tornado-Wise* by Vince Luciani. Available from Cologne Press, PO Box 682, Cologne NJ 08213. Soft cover, $3.95 plus $1.00 shipping and handling.

Grab the cat, Ma! Head for the cellar! The bloomin' TV set just went bright!

How many readers could apply a Sherlock Holmes analysis to those words and come up with the scenario of a tornado watch? A watch in which a family has been using the "Weller Method" of detecting killer tornadoes using a home TV set—and a funnel has just touched down!

Holmes would have had a problem in deciding whether the tornado detector was the cat or the TV set, although the modern detective would know it was the latter. Yet one day there may well be a study of the effect of tornado electrical radiation on cat's fur, for the subject, tornado electrical radiation, is quite controversial.

If you are among the few who have heard of the Weller Method, you may also be among those who remember what it is and—of much more importance to you, Ma, and the cat—how to use it properly.

Back in 1969, Newton Weller of West Des Moines, Iowa, had a garage packed with over 100 TV sets as he worked on his theory that the electrical radiation from killer tornadoes leaves a "signature" in the air for miles around, a signature that could be detected on an ordinary home TV set.

Technically speaking, the electrical radiation from tornadoes peaks very near to TV Channel 2, and Weller discovered that if you properly adjust your TV set's brightness control, the set could then respond to nothing but the tremendous electrical radiation from killer tornadoes. (A description of the Weller Method is given with this article. It should be read carefully before attempting to make use of the technique.)

When Weller had checked out every TV set marketed at the time (to make sure they would all respond properly as a tornado detector), he announced his discovery to the press via a Des Moines newspaper which printed the story a day before tornadoes struck the area. Weller's timing couldn't have been better, though Iowans claim that the probabilities of springtime tornado strikes are always uncomfortably high.

Iowans had a chance to check out Weller promptly, and some did exactly that. Several later wrote to thank him for his contribution to their welfare, explaining that their TV sets had, indeed, gone bright from tornado electrical radiation. This feature is the thrust of the Weller Method—that the electrical radiation from a killer tornado touching down will overcome a darkened screen and cause it to go as bright as a fluorescent bulb.

Closer to home, however, Weller commented, "My wife had all kinds of complaints about those TV sets in the garage, and if that strike hadn't happened when it did I might have given up on the whole idea."

Fortunately, he did not give up. Not that the weather service seems to care. The National Weather Service (NWS) has never cozied up to the notion of a mere TV set "broadcasting" tornado warnings on its own. Despite reports of successful results everywhere, Weller remains largely unrecognized for his work except in Tornado Alley.

NWS has conducted limited testing on tornado electrical radiation. One test, for example, was on a series

of strikes near the National Severe Storms Laboratory at Norman, Oklahoma. Those particular strikes apparently had reflected little electrical radiation—as happens with some—and based on those strikes, the report issued later disputed evidence of significant electrical radiation.

Apparently, several of the nation's leading meteorologists disagreed with the report, as was evidenced in counterpoints (somewhat biting) expressed to the NWS. There is, you see, quite a bit of controversy associated with tornadoes, and we really know very little about what causes them and what sustains them. More than cat's fur has been rubbed the wrong way in the argument over whether killer tornadoes pack significant electrical radiation.

While one side says there isn't any electrical radiation to tornadoes, the other side asks about those reports from people who have actually looked inside a tornado funnel and have lived to tell about it. Such reports have been of constant lightning, brilliantly-luminous clouds, "balls of fire," and rotating bands of deep, blue lights similar to those of an arc welder. And, they add, what about the reports of scorched vegetation along a funnel's path (later seen quite clearly from the air), and of the strong smell of ozone (so characteristic of strong electrical discharges)?

In a pig's eye, some have answered.

Pig's eye or cat's fur—the cat's got no one's tongue in the forever hanging controversy over tornado electrical radiation. The *subject* is quite electrifying, anyway, yet one seldom will read about this feature unless one subscribes to certain stuffy journals and is willing to wade through some weighty statements. Few contemporary writers who are meteorologically founded will broach the subject. Yet, the public has a need to know.

Readers should be able to choose for themselves. Perhaps, in a moment of off-season nonchalance, one may be inclined to stifle a yawn over a discussion of tornadoes, but if you are in the proper geographical area (as evidenced by having middle-range ZIP codes), and if it is getting on toward springtime, you are well advised to properly learn the Weller Method—its good points as well as bad.

And speaking of the bad side, it is, indeed, a fact that not all tornadoes pack the extent of electrical radiation that makes the TV screen go bright, which is why certain sides contend you've got holes in the bottom of your salt shaker if you even think the Weller Method is reliable.

"Of course it won't work with a weak tornado where the electrical energy is too low," says Weller. "But that weak tornado won't usually do much more than lift the roof off a hog shed—and even a straight windstorm will do that. The TV set *does* work on killer tornadoes, and they're the ones that count!"

Weller associate Paul J. Waite (Iowa State climatologist) has this to offer: "Until we have the perfect warning system, we should not neglect any opportunities to provide our populace with the means for self-protection from the ravaging destruction of tornadoes." Amen!

How close are we, these days, to perfection with NWS tornado detectors? Not very. Mostly, the NWS relies upon outdated vacuum-tube-type radars. Vacuum tubes, if you remember, were the gadgets that helped us advance our learning until we really took off with the discovery of transistors and solid-state circuitry. NWS definitely needs to replace those old radars.

Exactly, says the NWS, and they have proposed a $250 million network of modern Doppler-type radars, with a few of which they are currently experimenting. (Doppler, by the way, is a physical principle which involves motion detection; whatever else a tornado's funnel can be characterized as, it is certainly a dynamic picture of nature in motion!) But, a quarter-billion-dollar outlay in today's slash-everything economy? Not very likely.

Even so, Dopplers actually add very little improvement in the accuracy of tornado detection. They offer, instead, a significant increase in lead time once they do spot a for-real tornado. That *is* important. Lead time, as they like to say in Tornado Alley, carries a mite more concern in a tornado watch than does lead time on a rising covey of quail. Quite a mite more. It shouldn't surprise readers, then, to learn that the most effective tornado detector anywhere is the trained human eye. Which is exactly the talent NWS makes good use of via concerned citizens in an organization called "Skywarn." These are the civilian spotters throughout the country who offer their services

THE WELLER METHOD

1. Tune your TV set to Channel 13. Adjust its brightness control to make the screen nearly (though not entirely) dark.
2. Switch to Channel 2. Do not make any further adjustments to the set. The screen should still be nearly dark.
3. Sit and wait. If the screen suddenly flashes on brightly and stays lit, move fast! That's the indication that a killer tornado funnel is down anywhere within 5 to 15 miles of you—perhaps, quite near.

Notes

- Be careful, in Step 1, not to set the brightness control too low, or the set may be so desensitized as to not respond even to the tornado's tremendous electrical radiation. (For simplified understanding, consider tornado electrical radiation as being equivalent to a radio transmitter broadcasting on Channel 2; the analogy is reasonably accurate.)
- Some color sets cannot be made to respond to the brightness control adjustment. Be sure to check your set for this capability.
- If your color set does not turn down with the brightness control, your best bet (always) would be to use a portable black and white TV set for the Weller Method. The added advantage of being battery operated makes it useful when power lines inevitably go down in a tornado strike.
- If you are on a cable TV system, disconnect the cable from in back of the set and connect the built-in antenna.
- A local station on your Channel 2 may, during a tornado warning, cause the darkened screen to switch back and forth a few times from being brightly lit by the tornado to the local TV program. As the tornado approaches, its tremendous radiation will take over and cause the screen to stay bright.
- *Not all tornadoes pack intense electrical radiation.* Continue, therefore, to monitor news broadcasts either on a second TV set or by radio.
- Practice the Weller Method when lightning fills the air. Note how lightning affects your darkened screen, and become familiar with how dark to make the set. You will then be more sure of yourself when the time comes that your screen stays brightly lit.
- Be prepared ahead of time—you and your family—on what to do if the screen goes bright. Know your plan well enough to avoid panic reaction. Know what safety measures to take, and know them well in advance.

(often, quite courageously) for your benefit and mine.

People from all walks of life have taken up the public service banner in support of Skywarn, though perhaps no group has done so more completely, more effectively, than that special class of citizens known to us as amateur (ham) radio operators.

In Texas, for example, nearly 2,000 ham radio operators are on call to assist NWS when storm alerts are sounded. Most members take annual courses in tornado spotting, not only to improve their effectiveness but also to learn when to zig rather than zag as they are driving out there in the thick of things, spotting a downed twister as it snakes its deadly way across the plains.

Lone Star members of the hobby proved their worth at Wichita Falls, Texas, in 1979, when a series of killer tornadoes caused a half billion dollars damage. NWS credits the early-warning communications networks of radio amateurs with having saved 1,000 to 2,000 lives there. Such is the dedicated public-service nature of a hobby which includes ditch diggers, executives, and even a US senator!

Through it all, and continuing to survive the test of time (which is an admirable bottom-line characteristic to any theory) is the continuing undercurrent of support for the Weller Method. This is from an informed public, those who like the idea of having a detector for killer tornadoes right there in the house.

Not that the Weller Method works on every funnel that comes puffing and blowing down the field, but when the TV set does go bright . . . *"Grab the cat, Ma! Head for the cellar!"*■

TVRO Dish Selection Tactics

—Satellite Central, part V

Picking the right antenna for your TVRO can be dangerous! Too many people are ready to tell you that theirs is the best. Who can be trusted?

For example, we know the press release blitz touting the 3-foot dish for sparklie-free pictures was just a wild fantasy. All the hoopla was directed at the 12-GHz direct broadcast satellite (DBS), but somehow developed into identical claims for 4 GHz! The mere difference in frequency suggests that this isn't possible at 4 GHz. So you must arm yourself against those that would have you believe that the TVRO antenna department runs on magic!

At the moment, the biggest selling point is gain. But the three things you really should be looking for in a dish are *size, accuracy,* and *feed match.* Despite what sales claims may say, they all carry about equal weight!

Formula Blasts Wild Claims

Here's an easy way to rip away the veil of mystery concerning dish antenna gain versus size. Simply use this formula the next time you see a demonstration or see an ad touting high antenna gain. Just plug in the numbers to find the true gain.

$$\text{Gain in dB} = 10_{\log}(F^2 \times E \times D^2),$$

where F is the frequency in GHz (3.7), E is the efficiency in percent, and D is the diameter in meters. You can convert feet to meters by simply dividing feet by 3.28.

The trick to using the formula is knowing the efficiency of the antenna. While a quality dish may have 55 to 60 percent efficiency, the typical value for home-brew may only be 50 percent owing to poor surface integrity and feed design, as we shall soon see.

As a practical matter, you could stuff the formula into a programmable calculator and take it with you when you go dish shopping. Or you can type the dish gain program seen in Fig. 1 into a pocket computer such as the Sharp or TRS-80. It's only a few lines of code and may very well be worth the effort, especially when a salesman touts his 10-foot dish as having a whopping 43 dB gain! You can simply dig into your pocket and produce a better approximation of the true gain.

I saw an ad in another

The antenna wizard and his sacred tools of alchemy.

```
10 PAUSE "PARABOLIC DISH GAIN" : BEEP 1
20 INPUT "DIAMETER (FEET)"; D
30 INPUT "EFFICIENCY % (55)"; E
40 INPUT "FREQUENCY GHZ (3.7)"; F
50 D = D/3.2808 : G = 10*(LOG(E*(F*F)*(D*D)))
60 PRINT "GAIN = "; G
70 GOTO 10
```

Fig. 1. Calculate true dish antenna gain with this simple program for the Sharp or TRS-80 pocket computer. The program will run on almost any other computer supporting BASIC. What self-respecting computer doesn't nowadays? Only line 10 may need adjustment. The strange values in parentheses in lines 30 and 40 are suggested inputs.

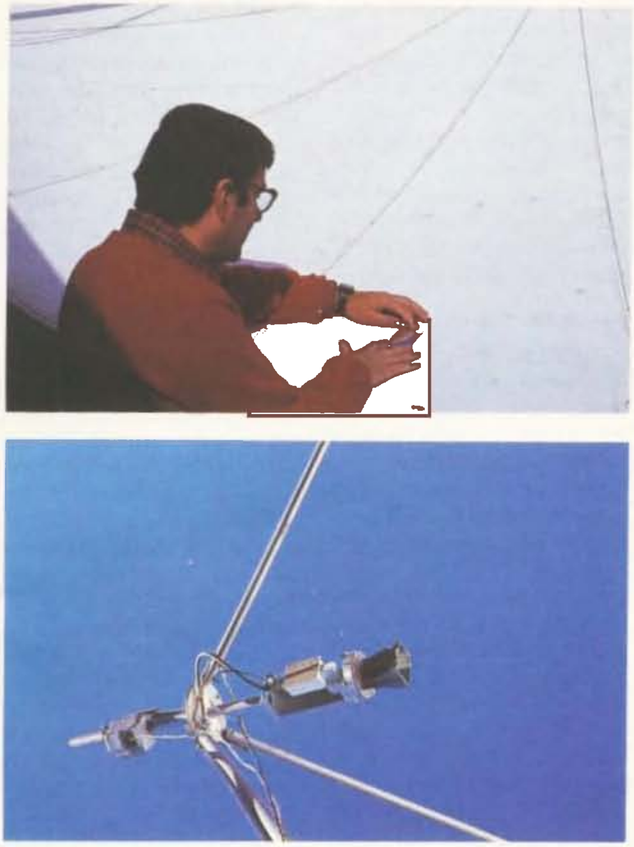

Fig. 2. Doing it with mirrors may tell you the whole story about dish accuracy. Use a small mirror and point the dish at the sun. The reflected rays should bounce into the feedhorn.

Fig. 3. A long pole or length of wall molding will reach anywhere on a dish and is safer. Tape the mirror to the pole like a hinge so it rests flat on the dish. Very few inexpensive dishes will pass this test. When you find one that does, buy it!

magazine recently that indeed claimed 43-dB gain from a 10-foot dish. This was beyond belief! In fact, I immediately tried to buy one because at 4 GHz, a 10-foot dish would have 100% efficiency and I wanted to be the first to own this eighth wonder of the world! But an excited call to their chief engineer revealed that he not only assumed 100% efficiency, but used a feedhorn known to achieve just 55% efficiency at best for this dish size and depth. He even did all his calculations at the high end of the band, which he was " told to do by the sales manager."

This is another trick you might want to watch out for. If gain is computed only at the high end of the band (4.2 GHz), you can make the numbers look nearly 1 dB hotter. Try it yourself. It's like adding nearly 2 feet to the dish diameter! This clever ruse can give the buyer or home builder a mistaken impression of the gain being the same at the low end of the band (3.7 GHz), which it isn't! After all, we do want to receive the entire band, don't we? You may think this an arbitrary point, which indeed it might be until you remember that just one single decibel in an FM system like this one can make the difference between a clear picture and a snowstorm. Many manufacturers today are calculating gain this way and you should know about it. *Caveat emptor!*

It's Not How Small You Make It

While it's possible to just get by threshold with only an 8-foot dish using a very low noise amplifier on a hot footprint, you will be better off using a 12-foot or larger dish for really sparklie-free pictures almost anywhere else. Even larger dishes may be necessary as you move off the footprint. Perhaps you recall from our past discussions that the LNA and dish operate on a kind of teeter-totter where a large dish can allow a cheap LNA to be used. Likewise, similar results are possible using a smaller dish and a higher grade LNA.

How small can you go? Eight feet is about the low end for wideband FM video due to the fact that the beamwidth and side-lobe response of smaller dishes let more ambient terrestrial noise reach the feed. Side-lobe response is very important with a TVRO antenna because the signal is about 30 dB or more *below* the noise.

It appears there's more to a TVRO antenna than just collecting a signal. It must also be a kind of rejector as well, a shield to the barrage of interference in the vicinity. It might be easier if the noise were man-made, but the music of the spheres is an annoying din, especially from our own particular sphere, *terra firma*, which demands we use ideas bordering on geometric optics to build workable antennas. As better and smaller antennas are designed, lower noise amplifiers will take up the slack in lost gain due to improved antenna shielding properties. But more work on this problem is needed. The horn/reflector is a very

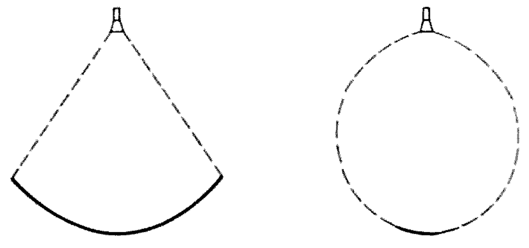

Fig. 4. Typical feedhorns fall off in sensitivity near the edge of the dish. Circular models may capture as much as 1 dB more signal. 1 dB is nothing to sneer at. It's like switching a 120-degree LNA for a more expensive 80-degree model!

good solution despite the plain fact that its large size makes it impractical at the moment.

How To Check Dish Accuracy

A really good dish will follow a parabolic curve to within plus or minus 1/16th of an inch. Achieving this accuracy is no easy feat. Some manufacturers will rightly say that such accuracy won't improve the gain, which is true to some extent. But the argument falls down flatter than a bad dish when side lobes are considered. Side-lobe response is directly related to surface accuracy.

Why are side lobes important? Remember, we are trying to hear a soft conversation in a room full of shouting people. The ambient noise floor at the antenna site may be −130 dBW, but the signal we want is a lowly −160 dBW . . . or worse. Only a narrow beamwidth dish with very low side lobes will receive it while rejecting the noise.

Now in the past, the only way to test a dish was to put it on a test range, feed it signals from a known microwave source, and plot a reception pattern. Then a few clever engineers worked out a method of antenna pattern plotting using noise from the sun. It works rather well but requires some test gear. A less accurate but easy way is to build a mating template that follows the ideal dish curve, place it in the dish, and hope it fits like a glove.

Doing It With Mirrors

But hauling a large template to a dealer or satellite show is not too practical. There must be a better way. And, of course, there always is, but long after you've completed the job, according to Murphy's law. Here's an easy trick I use to spot-check a dish. It's a real trial by fire. Simply place a small mirror anywhere on the reflector surface as seen in Fig. 2. Then point the dish at the sun and look where the reflected rays go. They should bounce right into the feedhorn!

If you imagine, for a moment, the sun as just another satellite, then the sun's rays should always hit the feed or else that particular portion of the dish isn't accurate. Try several spots on the dish. If the sun's rays don't make it, neither will microwaves! Right?

There are a few caveats to doing this test. First, use a small mirror. Less than 3 inches (one wavelength) is necessary. A larger mirror will only make things look worse. Second, crawling on a mounted dish isn't too safe no matter what latitude you're at. So the best method is to tape the mirror to a long pole or piece of wall molding as seen in Fig. 3 and move it around the surface. Third, wear dark glasses. You'll be looking almost directly at the sun. And fourth, don't be afraid of frying the LNA with this test. A flat mirror doesn't magnify. So a moment's reflection (despite the pun) will remind you that you are not increasing the LNA temperature more than you would if you simply pointed the bare LNA at the sun!

Feeds Are the Culprits

Perhaps you recall from last month's discussion that feeds limit antenna efficiency to the 50% to 60% range because their sensitivity pattern cannot adequately cover a dish. See Fig. 4. The ideal feed pattern would be flat as a pancake across the top and drop to zero at the sides. But that's not all. The manufacturer of this fabled horn would need several models, one for each size dish, because any overshoot by the horn would add a considerable amount of terrestrial noise to the signal and breed the dreaded "sparklies" faster than rabbits.

Back now to the real world. A lot of work was done on feedhorns in the '60s, mostly by radio astronomers. Their ideal feed overshoot occurs when the edges of the dish are illuminated at a level which is −15 to −20 dB down from the center. As a practical matter, TVRO designers use the −10-dB point on the curve. At the moment, several manufacturers offer nearly identical feeds that cover a narrow range of dish sizes and F/D ratios. Depending on dish size, a typical horn will operate over an F/D range of .3 to .5 with moderate efficiency. F/D is simply dish focal length divided by the diameter. Some companies will design a feedhorn for your specific dish. All that varies is the flare angle of the horn, which directly affects the angle of the illumination pattern.

Watch For Sleight Of Hand

If you see a demonstration where a small dish is used and the pictures look fine, stop and ask yourself if the salesman is showing you only the best transponders. Test your suspicions by asking if you can do the tuning. Then try all the transponders. RCA birds (Satcom) have 24 transponders, while Western Union birds (Westar) have only 12. Not all transponders lay the same footprint levels in a given area, so you must test. In many cases, you may find the test being conducted on a bird which may have a hot footprint in your area. Ask to see what all the transponders look like on other birds. It may be wise to have a log of what is available. A complete list of program sources and times on all the satellites is available from *Satellite TV Week*, PO Box 308, Fortuna CA 95540, (707)-725-2476. Cost is $48/year or $65/year, first class.

You may discover when you have free reins on the tuning knob that many transponders are buried in the sparklies. Throw the salesman off guard by asking why! The answers you get may cause you to reconsider a purchase. Be prepared for the interference argument. It may be valid. Quite often you may discover that satellite TV in your area will be plagued with interference from Ma Bell. At this point, you must be on special guard because location of the dish becomes very important. While your house can make a dandy shield to a direct signal, you must also narrow your search to a very high integrity dish so the side-lobe levels are at their lowest. This problem may cause you to re-think your location. A large rf fence is an eyesore even to the most understanding wife.

Of course you can stifle the interference to some

degree with notch filters in the receiver i-f. As a rule, Ma Bell carriers are located plus and minus 10 MHz from the center of a typical transponder. If you install notch filters at 60 and 80 MHz in a typical 70-MHz i-f amplifier, the interference will be drastically reduced and may turn an otherwise unwatchable picture into something that can be viewed, though not fully appreciated as studio quality, mainly because notch filters remove some of the signal you want to receive!

Magic Without Mirrors

Antennas for TVROs are no more different than for any other service when it comes to the rock-solid basics. But you must be on the lookout for magical claims because this field is new to the entrepreneur types who sell only the sizzle. There is a tendency among many (including myself) to buy a product because the advertising is slick or the numbers in the ad fit your calculations and pocketbook.

The problem is "newness." If you see everyone getting fantastic pictures with an Acme Whizbang Launcher, then it must be pretty good. But very few people even know what a TVRO is, let alone a Whizbang whatever. So it's up to you to break the new ground, to make the mistakes. . . and claim the victories. Just be careful and remember that a wise man always looks before he leaps.

The time is right for you to join in the fun of receiving TV from space. If you have a question regarding the topics we cover here, feel free to drop me a line (letters only, no calls please). Sorry, I can only answer mail that is accompanied by an SASE. ■

Taylor Howard: TVRO Trailblazer

Tim Daniel N8RK
73 Magazine Staff

Taylor Howard W6HD has been called many different names. He didn't mind when the Australian government nicknamed him the "Crazy Professor," but when opponents of the home-TVRO industry labeled Howard as a "pirate," he got mad. "There are pirates out there," Tay Howard freely admits, "but why should I be prohibited from receiving signals that I can't get any other way?"

For Dr. Taylor Howard, the future of satellite TV is a very serious business. Ever since he built the world's first private Earth station, W6HD has been in the forefront of the battle to legitimize the infant home-satellite-TV industry. The debate centers on the availability of services. Howard just wants access to the same entertainment and information that cable TV customers can get.

"I don't want to be a second-class citizen just because I don't live in a condo in New York" is his argument. Without missing a beat he goes on to acknowledge the need for Earth-station owners to pay a fair price for these services.

Tay Howard brings a unique viewpoint to the upstart TVRO field. His heart really lies in the workshop or laboratory, not in a congressional hearing room or courthouse. Howard, along with another ham, Robert Coleman, built the first satellite receivers that the average hobbyist could duplicate. The original Coleman-Howard design is at the root of most of the commercial receivers sold today. Other W6HD innovations include specialized TVRO test gear and a low-cost method of changing the polarity of a feed.

Today, Dr. Howard devotes most of his time to serving the TVRO industry as a spokesman and consultant, but he remains on the faculty at Stanford University where he contributes to NASA's deep-space exploration program. A major chunk of his time has been spent as member and the first President of SPACE (Society for Private and Commercial Earth Terminals), which represents the terminal owners and manufacturers.

The nickname "Crazy Professor" was given to W6HD when he proposed a satellite reception scheme for Australia's outback. Government officials said it couldn't be done—that the signals just weren't strong enough. Howard chose to ignore the doomsayers. After building a big spherical antenna, he attached a receiver and then sat back to watch TV. The aborigines, the government, and even some of Howard's backers were amazed. There wasn't any magic involved; Howard knew that the theory permitted success, but only if someone took the time to try.

In his quiet, yet confident manner, Taylor Howard offered the following thoughts:

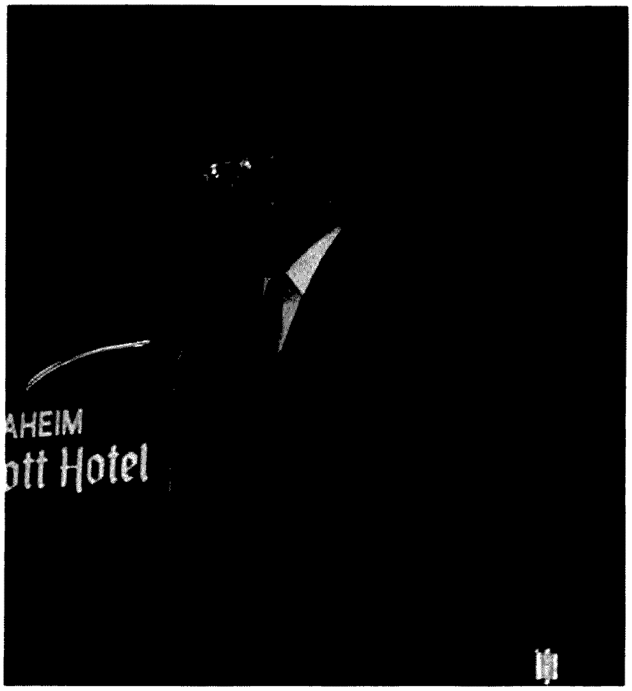
● 12-GHz Direct Broadcast Satellites: Aren't the 4-GHz satellites already direct broadcast? Technically, 12 GHz is not that far away. The problems are legal. Even the Europeans are having trouble. There is no way to limit the pattern of a satellite's signal to a country's geographical borders. The threat of cultural imperialism must be solved before the world is ready.

● Impact of Video: Satellite TV can have a positive effect on people's lives. It brings them into the mainstream of life regardless of where they live. Modern kids are pretty good about television. They know the difference between good and bad.

● Microwave Technology: Signal processing has been the downfall of the microwave industry. We need to learn how to integrate the entire system into one package. This would help reduce the expense for uplinking to satellites.

● Opportunities: Hams are a natural for getting involved in the satellite-TV field. We are totally short of competent people. There could be employment for every ham in the country. You need both digital and rf knowledge and the ability to combine the two. An understanding of transmission-line theory is important.

● Appliance Operators: There are lots of hams who are yakkers; you might say that they have a PhD in CB. But that is okay; we need people like that. I've always been technically inclined and will protect the individual experimenter.



Taylor Howard W6HD.

You won't find Tay Howard with a patch over his eye, stalking the deck of a galleon. Look for him in the Australian wilderness, a college laboratory, or in his dish-filled backyard. He won't be searching for buried treasure. Instead, he may be gazing skyward. Taylor Howard is a pioneer, not a pirate, and for him, satellite television is going to be "big, very big; we haven't seen anything yet!" ■

TVRO Q & A

—advice from WB0POP—part II

Ken Rae WB0POP
737 South Clarkson
Denver CO 80209

I found a great deal for a surplus antenna. The only problem is that it's bent. Can it be straightened?

Dents in a metal dish usually can be pushed out with a piece of wood. If the dish is warped from rim to rim, the antenna is probably hopeless unless you remold the entire surface. If the cure is not simple, then start looking for another antenna.

Fig. 1. A wooden template can be used to check the accuracy of an antenna surface.

How can I measure the accuracy of a dish?

The first step is to find the focal point and diameter. Next, using the appropriate equation, draw an accurate representation of the parabolic curve on a large piece of paper. This paper model can be used to make a wooden template that can be lined up against the dish to check its accuracy—see Fig. 1. (The most useful type of template has two of these "half moons," mounted at right angles.) You can check the rim by laying the dish face down, on a flat surface like a level concrete floor. A quick field test can be made by stretching two strings across the dish at right angles (see Fig. 2). A deflection or gap between the two strings indicates that part of the rim is bent or warped. If the rim is true, the two strings should just touch in the middle.

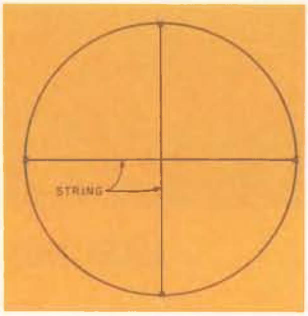

Fig. 2. Two pieces of string stretched at right angles should just touch the middle if the rim of the dish is true.

A friend of mine is thinking about buying an oval-shaped dish. The price is right, but will it work?

Unfortunately, an oval-shaped antenna would be next to useless, no matter what the price. The bore sight of an oval dish is not circular, so you will receive a mixture of horizontally- and vertically-polarized signals. This is unacceptable for conventional TVRO work.

What are my chances of finding an appropriate surplus dish?

You might be better off searching for a bikini-clad beachcomber in Denver during the dead of winter. The tremendous interest in TVRO has made surplus antennas a scarce commodity. There are a few hiding in corners of junk yards waiting to be scrapped. Others are being retired from commercial service. In any case, you'll have to do a lot of looking and have the right contacts.

I can't find a surplus antenna, nor can I afford to buy a new dish. What is my next option?

You can build your own antenna. The spherical de-

sign is probably a little bit cheaper and easier to duplicate than a parabolic, but it is also less versatile. If you are good at scrounging materials, you can build either a parabolic or spherical antenna for $100 to $400. However, don't underestimate the amount of work involved.

What about building a stressed dish?

Amateurs have been experimenting with this type of parabolic antenna for many years. Unfortunately, most stressed-type designs are not intended for continuous exposure to the elements. For best results, a stressed antenna must be guyed in position, eliminating the ability to change satellites easily.

Is there a simple way to spot potential obstructions between my antenna and the satellites?

Go to your tentative site and look due south. Raise your arm to about 45 degrees from horizontal. Sweep your arm across the sky, dropping it down as you move to the east or west. If you live in the central United States, this will give you a rough idea of the satellites' location. If there are trees, buildings, or other obstructions that look risky, take the time to run a serious check on the site.

What is the maximum distance I can have between my TV set and the satellite antenna?

If you are using a single-conversion receiver where the downconverter is located at the antenna and a 70-MHz signal is sent to the house, there can be as much as a 100-foot run of RG-8/U coaxial cable (or perhaps a good grade of RG-58) without losing a noticeable amount of the signal due to cable loss. If your system requires that you relay a 4-GHz signal, it will be necessary to run hardline or heliax cable, which costs as much as $4 per foot, or about ten times the cost of RG-8/U. If you do use a good grade of hardline, it can usually be 80 to 100 feet long before the losses catch up and degrade the picture. Line amplifiers can be added to increase this distance, but the cost may be prohibitive.

My neighbor is considering installing her own TVRO. Could that interfere with my system?

Just as hams living next to each other sometimes have interference problems, so can adjacent TVRO systems. The difficulty usually stems from local oscillator (LO) leakage. This unit typically has 10 milliwatts of output, and if it is not well shielded, a signal will be radiated. If your neighbor wants to receive a signal on the same frequency that your LO is operating on, there could be a problem. Dual-conversion receivers or well-shielded single-conversion designs go a long way towards reducing the interference.

What is an Az-El mount?

This type of mount allows you to move a dish vertically (El) and horizontally (Az). In my opinion, this is the hard way to do things unless you are chasing satellites that move, like Russia's Molniya birds. If you'll be watching only the geosynchronous satellites, a polar mount is probably more useful.

OK, what's a polar mount?

The polar mount allows you to rotate the dish from east to west or vice versa and keep the axis of the dish in line with the axis of the Earth. You can align the axis for a polar mount by using the North Star as a guide. When you sweep your dish across the sky, it will not be necessary to make any significant adjustments in the elevation if you have a polar mount.

What is a "tree" mount?

There is no strict definition for a tree mount. All you do is prop your dish against a handy tree, the side of a building, or anything else that is convenient. This kind of mount is useful if you are in too much of a hurry to build a polar or Az-El mount.

How do I center the feedhorn on a dish?

To place the feedhorn at the focal point requires measurement from the center of the feedhorn's mouth to the edge of the dish. This distance should be the same to all points on the edge.

When I was positioning my feedhorn, I found a better signal when the horn was slightly off center. Why?

If your signal improves when the horn is not centered, there may be two culprits: The dish is not pointed directly at the chosen satellite or the antenna's surface is warped, causing the actual focal point to differ from the theoretical focus. A distorted dish may have one or more false "hot" spots. On a well-built dish that is pointed directly at the satellite, your best signal will be found when the feedhorn's mouth is at the calculated focal point.

I have a good dish and I know it is pointed right; I still get two hot spots, one at the edge of the feedhorn mouth, the other just inside the horn. What gives?

When you move the horn back and forth through the focal point, there will be two distinct "hot" spots. The wave pattern has an hourglass shape since the impedance seen by the arriving signal changes according to the distance. The hot spot that is closest to the dish is the most efficient because it offers a narrow bore sight. This means that the focal point will lie about ¼ to ½ inch inside the horn.

When placing the horn, which is more critical, moving the mouth from side to side or moving it towards and away from the dish?

A two-inch shift to one side can result in as much as a 3-dB drop in signal level while a two-inch movement in or out will result in a 1-1.5-dB loss. Concentrate on lining up the side-to-side dimension.

As I sweep my dish across the sky, there is a slight "image" signal about four degrees on either side of the bore sight position for a particular satellite. What is this?

I discovered the same thing when I was installing a new antenna. First I thought it was a new satellite. After disproving that theory, I spent many hours carefully refocusing my antenna. Finally, after a lot of reading, I discovered that any parabolic antenna that is not perfect will exhibit side lobes. These will allow you to receive signals that are much weaker than those you find with the major lobe pointed at the satellite. The better the dish, the less prominent the side lobes.

Why do I receive vertical transponders better than horizontal transponders on the same satellite?

On Satcom F1, the vertical transponders were slightly stronger than the horizontal ones, but the one-half-dB difference was not enough for most hobbyists to notice. If you have a noticeable difference between the two polarities, it may be the result of inaccuracies in the antenna's surface. ■

VHF Converter

—easy to build, yet state of the art

Editor's Note: This state-of-the-art VHF converter design is reprinted from the British publication *Radio and Electronics World*. A complete parts kit is available from RadioKit, Box 411, Greenville NH 03048. The special TOKO coils are available from Ambit International, 200 North Service Road, Brentwood, Essex CM14 4SG, England.

Despite the plethora of ready-made equipment for the 2-meter (144-148 MHz) amateur communication band, most radio enthusiasts like to try to salve their consciences as participants in the once exclusively "practical" art of amateur radio by making at least one or two items of equipment that can justifiably be described as "home grown."

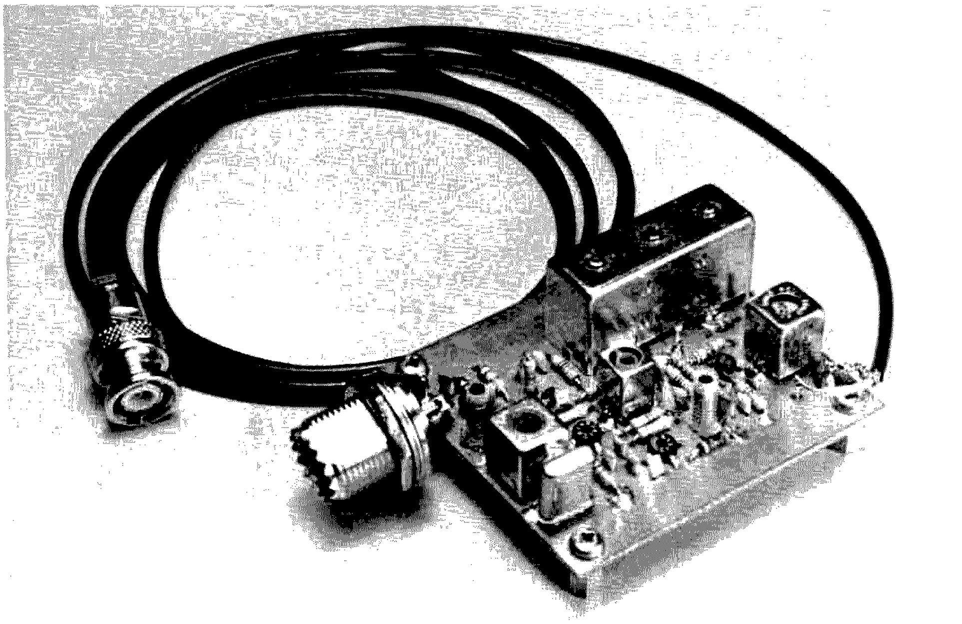

Photo A. The finished unit with cable.

Most of the commercial transceivers for the VHF bands are primarily FM systems for simply "nattering," and some of the hobby's traditionalists might suggest that the use of 2m NBFM bears more than a passing resemblance to the principles behind CB radio—but that's an entirely more contentious subject. . .

The exclusive use of NBFM tends to overlook the more interesting aspects of CW and SSB communications (Morse code and single sideband to the uninitiated). But since most enthusiasts have an HF communications receiver (or two) at their disposal, it is an easy enough task to

Specifications

Noise figure	less than 2 dB
Gain	28 dB nominal
3-dB bandwidth	144-146 MHz
I-f output	28-30 MHz
1-dB compression	+ 5-dB output
Saturated output	+ 7 dBm
Supply voltage	8-16 V
Supply current	15 mA nominal
In-out impedance	50 Ohms
Size	70 × 60 × 20 mm

make a thoroughly professional converter for 144-146 MHz, with an i-f output to be tuned on the 28-30-MHz section of the HF receiver. The radio enthusiast may thus fulfill the repressed constructional instinct, as well as be able to have a serious look at the CW and SSB aspects of the 2-meter band before launching into a few hundred dollars worth of oriental temptation.

The converter is basically a linear device within the expected range of input signal levels, so any mode (AM, FM and SSB) can be converted to the required HF output. Some HF receivers are available with NBFM demodulators, but to do the job properly, the correct bandwidth i-f filter needs to be used with a purpose-made NBFM i-f system. In the absence of this facility, slope detection of NBFM is better than nothing. (Slope detection relies on the i-f filter passband edge to translate the frequency modulation information into an amplitude variation for detection as simple AM.)

Judging by the numbers of "nearly new" SSB transceivers advertised for sale, it is no doubt better to investigate your long-term interest in this aspect of communication without first contributing to the wrong side of the balance of payments. This converter provides reception of repeaters, NBFM simplex, and demanding long-range communications using CW or SSB.

The 2-Meter Converter

This converter was originally designed to complement the RX80 receiver described in the British magazine *Radio Communication*, although it will obviously operate with such receivers as the FRG-7, R1000, DX160, etc. It has been designed with the latest state-of-the-art components, notably the NEC 3SK88 MOSFET which has been chosen for its repeatably low noise figure and low cost. The TOKO CBT series helical filter provides an outstanding bandpass and stopband response, but most significantly of all from the point of view of those of you wishing to duplicate this converter, it is supplied prealigned and requires virtually no trimming to optimize alignment.

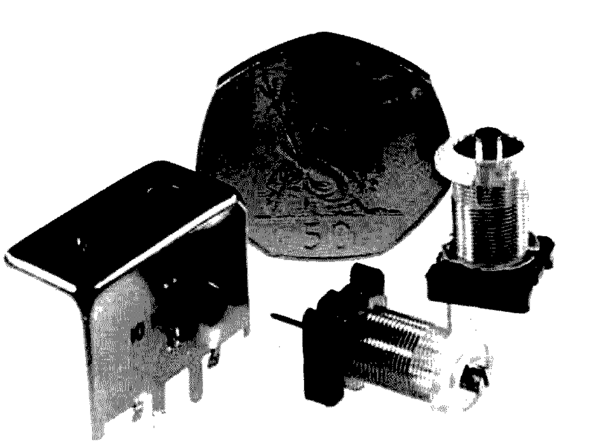

Photo B. An exploded view of the 2-pole version of the helical filter.

Although a VHF converter usually requires considerable expertise and recourse to a selection of signal generators and other analytical equipment, the converter can be built by anyone with kit building experience and a multimeter.

Circuit Description

Fig. 1 shows the complete circuit diagram. C1, C2, and L1 provide the optimum noise match between the 50-Ohm antenna input and the rf amplifier—this is a carefully derived selection of values, and not simply a haphazard choice from the junk box. Gate 2 of Q1 is biased at 5 V (externally derived—i.e., from the main receiver or tuneable i-f—negative-going agc may be applied at this point by those with adequate confidence and experience). The source of the rf amplifier, Q1, is then taken directly to ground to ensure minimum impedance.

The drain of Q1 is taken to the supply through R3, which provides the correct terminating impedance to the helical resonator, L2,

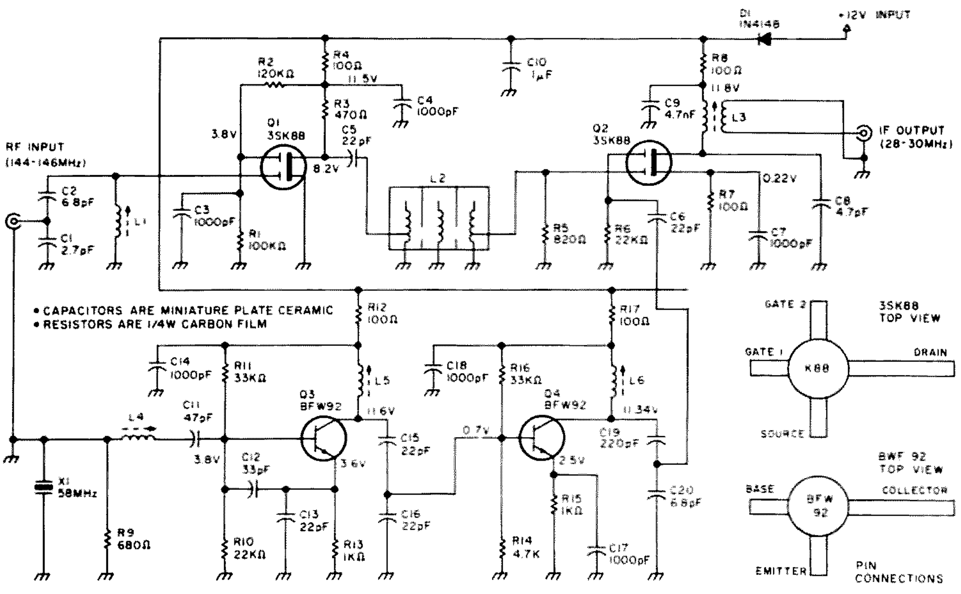

Fig. 1. Circuit diagram.

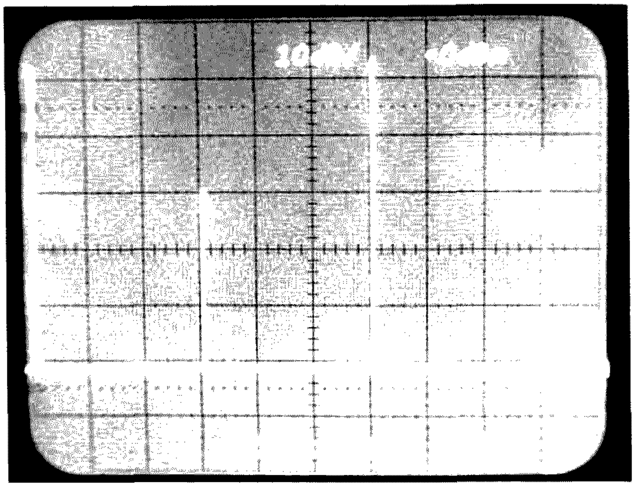

Photo C. The spectrum of the LO multiplier output (10 dB per vertical division, 20 MHz per horizontal division).

which has an input and output impedance of approximately 450 Ohms. The output of L2 is connected straight to the gate of the mixer, Q2, R5 providing the necessary extra load in parallel with gate 1 of Q2 for a correct 450-Ohrn matching load.

The appearance in the market of low-cost helical filter blocks (Photo B) will probably change the approach to VHF designs, since yet another circuit variable has now been substituted by a building block that takes out most of the problems for the less-experienced designer and user. More than 75% of the problems associated with VHF radio designs are simply those associated with getting lost in the MHz as a result of the uncertainties of DIY coil designs.

Helical filters will not salvage designs that fall into the all-too-familiar abyss of "dry" joints and a shortage of basic experience in handling components and a soldering iron—but these filters will help allay the fears of the more experienced audio constructor whose neat rf projects have always been relegated to the "pending" tray, since the problems of alignment associated with the green fingers of the rf engineer sometimes seem insurmountable.

Unlike the rf amplifier, the mixer does not use any dc bias on either of its gates. This is because the amplitude of the local oscillator injection voltage is designed to be sufficient to switch Q2 *directly* at 116 MHz, thereby improving the intermodulation performance of the converter. This technique is used in some professional receivers and is similar in concept to the esoteric Schottky diode double balanced mixer—except, of course, that this system is single ended. It is possibly the first time that this approach has been used in an enthusiast's constructional feature. Unless you know better...

At the drain of Q2, the wanted mixer product (28-30 MHz) is selected in the tuned circuit formed by L3 and C8 and matched at the secondary to 50 Ohms to feed the main receiver. It is this output network that mainly constitutes the 3-dB bandwidth of the converter. This means that the gain is approximately 25 dB at 144 MHz, 28 dB at 145 MHz, and 25 dB at 146 MHz. This reduction of gain is of no consequence as the design has plenty in hand at all times.

It should be noted that the ultimate sensitivity of any receiving system is defined by its noise figure and *not* its gain. This means that the sensitivity will be the same over at least 144-146 MHz, although the S-meter might read slightly less at the band edges.

The oscillator chain uses a 38.667-MHz crystal rather than the more usual 116-MHz type. Transistor Q3 serves the function of both oscillator and frequency doubler. L4 tunes out the capacitive reactance presented to the third overtone crystal and allows fine adjustment of its operating frequency. L5, C15, and C16 select the third harmonic from the oscillator at 116 MHz and match it into Q4 where it is amplified to an adequate level to switch the mixer, Q2. The capacitive divider, C19 and C20, provide the necessary level and impedance adjustment to feed the oscillator injection of approximately 2 mW to gate 2 of Q2.

On a general point about decoupling, note the way in which tuned circuits are decoupled with capacitance and inductance. Taking the example of L3 (R8/C9), R8 is apparently superfluous.

This presumes that there is zero ac impedance to the rf ground on the positive supply rail which—for reasons of the effects of lead inductance and the unpredictability of stray coupling at VHF—is certainly not always the case. Thus the low-pass filter formed by the RC combination provides a far more positive and reliable method for keeping the rf off the supply line. The danger of creating a positive feedback loop somewhere in the physical (as opposed to the-

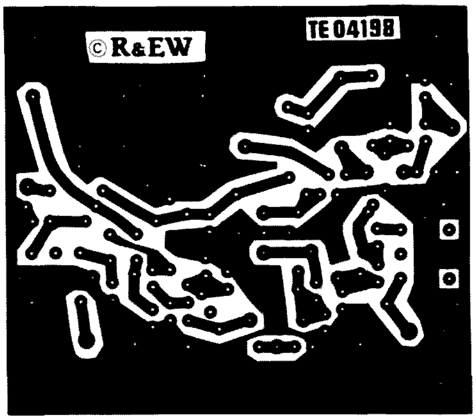

Fig. 2. PC board layout.

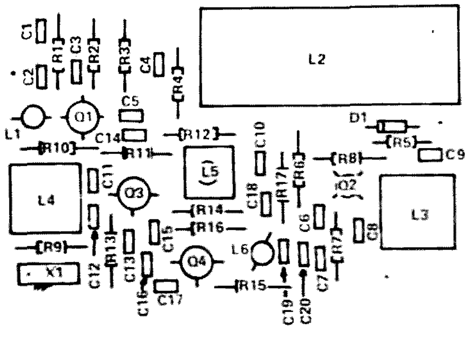

Fig. 3. Parts placement.

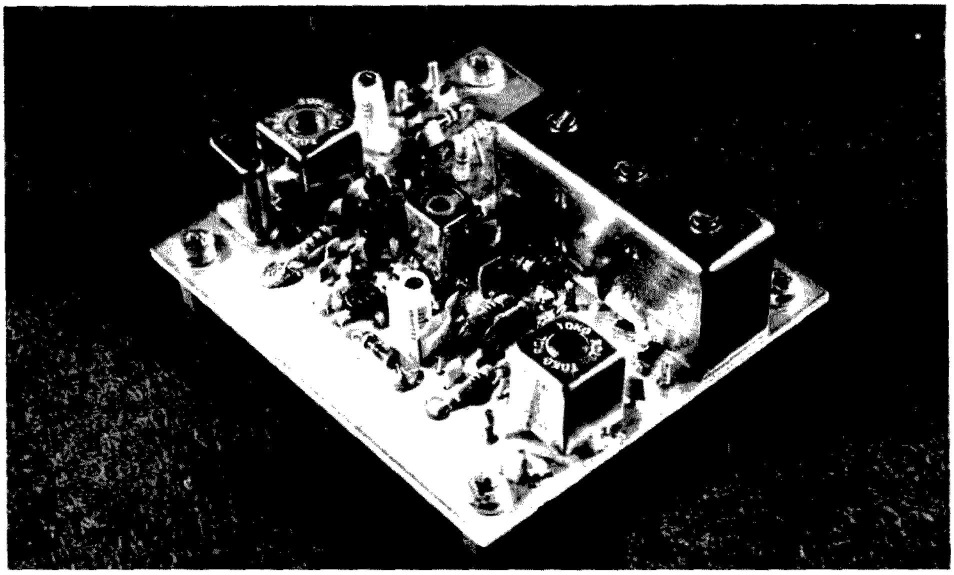

Photo D. The completed converter PCB.

oretical) circuit layout is thereby greatly reduced.

D1 provides reverse polarity protection, which most readers with practical experience will have discovered is essential when connecting things up in a hurry. Strangely enough, this simple and effective precaution is omitted from many designs. Perhaps more components get sold that way.

Construction And Alignment

Using the PCB and components placement guide (Figs. 2 and 3), assemble the converter. Do not forget to solder the earthy legs of R1, R5, R6, R7, R9, R13, R14, and R15—and also the can legs of L2, L3, L4, and L5. There are no critical or easily-damaged components, although due to their size it is advisable to leave the coils and helical filters until last.

After construction is completed, remove any solder splashes, check for dry joints, and remove the flux residue. Connect to a 12-V regulated power supply and check that the current consumption is about 10 mA without the crystal fitted.

Preset coils L1, L5, and L6 so that their cores are flush with the top of their formers. At this stage, do not touch L2, L3, and L4.

Connect a voltmeter between Q3 emitter and ground; the voltage should be approximately 3.2 V. Plug in the crystal, and the voltage should rise to about 3.5 V; slightly adjust L4 for maximum reading. Transfer the meter to Q4 emitter, and adjust L5 for maximum reading—which will be about 3.5 V. If the crystal is removed, the voltage will fall to approximately 0.48 V. Transfer the meter to the source of Q2 and adjust L6 for maximum reading. This will be about 0.15 V to 0.3 V, depending on the IDSS of Q2; there will be less than 0.1 V present with the crystal removed.

Connect a 50-Ohm aerial to the 2-meter input and a suitable receiver to the output via a 50-Ohm coax lead. Don't bother to tuck it all away neatly into a case/box just yet, since there is a reasonable chance that you will need to do some work on the unit to get everything working perfectly.

Tune to a weak signal around 145 MHz (the output will tune to 29 MHz) and adjust L3 for maximum output using the receiver's own S-meter. Adjust L1 for maximum signal-to-noise by ear, and do *not* use the S-meter if optimum results are required. Maximum gain does *not* coincide with minimum noise figure.

Unless you have the necessary equipment to sweep the 2-meter band with a spectrum analyzer and signal generator, do not adjust L2. There is little point anyway, as the helical resonator has been very accurately set up during the course of its manufacture and test, and no improvement could be effected on the samples tested. This is not unexpected, as TOKO offers an unparalleled repeatability in their ranges of high quality rf and i-f coils. Experience has shown them to be suitable for most demanding applications, and, indeed, there are hardly any high-quality receivers that do not use some.

The bandpass characteristic over 144-146 MHz shows a perfect textbook response (Photo C). The helical filters were originally designed for use by manufacturers of Oriental "black boxes." If you take the lid off some Kenwood and Standard equipment, you probably will find one of these devices lurking near the receiver front end.

The remaining adjustment is to put the converter onto the correct frequency, but this is not important unless the receiver itself has an accurate frequency readout. If it has, then tune to a known frequency such as a beacon signal or a repeater and adjust L4 so that output frequency corresponds to the known input signal. For example, a repeater on R6 (145.75 MHz) reads 29.75 MHz on the main receiver display.

This completes the alignment, and it is gratifying to be able to comment that no problems have occurred with stability in any examples tested so far—doubtless due to the carefully designed double-sided printed circuit board.

Conclusions

Once you are confident that all is well, fit the completed PCB into an appropriate container and fit

some form of rf connector such as PL259 or BNC. If you do not already possess a standard of your own, then the BNC system is probably the best choice. Fitting a BNC connector to a cable is not the easiest task for the uninitiated, but it is worth persevering and acquiring the necessary skills, since the BNC system is probably the best general-purpose rf connector available.

The spectrum analyzer photographs were taken using Tektronix and Hewlett Packard test equipment. Because the input and output frequencies are not the same, it was not possible to use the conventional technique of sweeping a tracking generator with the spectrum analyzer. Instead, a Hewlett Packard 8640B signal generator was swept by hand over 130-160 MHz while the spectrum analyzer was tuned to a center frequency of 29 MHz. The resulting display was stored in the analyzer and photographed with a Polaroid camera. The results speak for themselves and, best of all, are entirely repeatable.■

—BASIC message handling

William M. Kahn WA6ZZL
13450 Highway 8, Space 3
Lakeside CA 92040

When I first began handling formal message traffic, I was impressed with the professional "Western Union" look of the amateur radiogram forms published by the ARRL. Several months later, the romance ended as I reorganized desk drawers for the umpteenth time to make room for my ever-growing message file.* So, I began to design a program

***FCC regulations (Section 97.105) require retention of third-party traffic for one year.**

Program listing.

which would allow me to copy traffic directly onto my micro keyboard and store all my third-party messages in a cassette data file.

The program is written in Radio Shack Level II BASIC for the TRS-80 microcomputer and occupies less than 6K of RAM. This includes 3.2K reserved for the string inputs but does not include any overhead for the BASIC interpreter (12K of ROM in the TRS-80). Users of other systems may have to adjust accordingly. As is, this program will handle up to ten messages in the ARRL radiogram format. If you have less available memory, just reduce this capacity to fit your own needs. Any micro with 4K of available RAM should store up to four messages quite nicely.

Operating the program is simple. You begin by making keyboard entries of up to ten messages. The inputs for each message are in the same sequence in which they are normally received off the air (lines 80-200). The transmitting station usually gives a "break" before sending the actual text, and line 130 provides an opportunity to correct any errors or missed copy up to that point. Following the "TEXT & SIGNATURE" input in line 200, enter the information required in the "RECEIVED FROM" section of the radiogram form. The second statement in line 200 recalls the message number and precedence in case the message heading has scrolled off the display screen. (It can be embarrassing to acknowledge receipt of a message when you have forgotten the number.) When you are finished entering traffic, each message entered is displayed in subroutine 20000 and the "STATUS" of each (corresponding to "SENT" on the ARRL form) is entered. You may then continue making entries or dump what you have into a data tape (subroutine 30000).

Note the branching arguments and string comparisons in lines 212-310. These allow repeated use of a single string set (H$, N$, etc.) for the inputs and assign the final string names when each message is complete. On the tenth run, there is no change of string names.

Once you have established a message data file on tape, you can make inputs from this file at the beginning of each run (lines 4010-4110). Lines 4120-4220 print the "HEADING," "RECEIVED FROM," and "STATUS" sections of each message for a quick review. You may then either load the next series from the tape or review each message and make additional keyboard entries. Note that if you wish to combine tape and keyboard inputs in the same run, you must make the tape input first. The

ELECTRONIC HOBBY INNOVATIONS

7510 GRANBY STREET SUITE 207 NORFOLK, VIRGINIA 23505

number of messages available for keyboard input depends on the number loaded from the tape.

Since each "TEXT & SIGNATURE" input is a single string containing a maximum of 255 characters, some kind of line-length control is necessary in order to avoid breaking up words at the end of each line of text. Careful use of the space bar will accomplish this, but it consumes string space in the process. I prefer to use the "down-arrow" key on the TRS-80 keyboard. It performs a line feed/carriage return function without wasting memory and is excellent for separating the signature from the body of the text.

Notice the tape input and data dump sections (lines 4000-4110 and subroutine 30000). These functions are executed by the "INPUT#" and "PRINT#" statements. The phrase "−1" is required in Level II BASIC for multiple cassette deck control.

The series of "PRINT CHR$(10)" statements in subroutine 20000 execute the ASCII control code for "line feed/carriage return." The same result can be obtained by using separate PRINT statements for each string.

Finally, lines 4280-4310 are keyed to a separate but related program which automatically computes monthly traffic statistics from the data file. There is no effect on the resident program and the inputs are easily bypassed.

Whether you are presently handling a lot of traffic, a little traffic, or are now tempted to try traffic handling for the first time, I think you will find this program to be valuable and fun to work with.■

SOCIAL EVENTS

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received two months prior to the month in which the event takes place.

FLEMINGTON NJ
APR 3

The annual Flemington NJ Hamfest will be held on Saturday, April 3, 1982, from 8:30 am to 3:30 pm at the Hunterdon Central High School Field House, Flemington NJ, located between New York City and Philadelphia at the intersection of Rtes. 202 and 31, just 10 miles south of I-78. Admission is a $3.00 donation. There will be a flea market with a large heated indoor area, 200 tables, major manufacturers, and more. Talk-in on 146.52, 147.015, 224.12, and 224.54. For reservations or further information, call (201)-788-4080, or write Cherryville Repeater Association, c/o W2FCW, Box 76, Farview Drive, Annandale NJ 08801.

MEMPHIS TN
APR 3

The Memphis Mini-Fest will be held on Saturday, April 3, 1982, from 8:00 a.m. to 5:00 p.m. at the Pipkin Building in the Mid South Fairgrounds. Admission is $1.00. Flea market space is $5.00 or 2 spaces for $8.00 (bring your own tables and chairs; none will be furnished). Doors will be open at 6:00 am for unloading. There will be a hospitality party Saturday night at 7:30 p.m. For further details, contact Clayton Elam K4FZJ, President, Mid South Amateur Radio Association, 28 N. Cooper Street, Memphis TN 38104, or phone (901)-274-4418 (days) or (901)-473-6714 (nights).

ROCHESTER MN
APR 3

The Rochester Amateur Radio Club and the Rochester Repeater Society will sponsor the Rochester Area Hamfest on Saturday, April 3, 1982, at John Adams Junior High School, 1525 NW 31 Street, Rochester MN. Doors will open at 8:30 a.m. There will be a large indoor flea market for radio and electronic items, prize raffles, refreshments, and plenty of free parking. Talk-in on 146.22/.88 (WR0AFT). For further information, contact RARC, c/o WB0YEE, 2253 Nordic Ct. NW, Rochester MN 55901.

OAK RIDGE TN
APR 3-4

The Oak Ridge ARC will hold the fourth annual Oak Ridge Hamfest on April 3-4, 1982, at the Civic Center, Oak Ridge TN, from 9:00 am to 5:00 pm. Admission is $3.00 and accompanied children will be admitted free. There will be an indoor dealer display, forums, prizes, concessions, and an outdoor flea market. Talk-in on 146.28/.88, 147.72/.12 (backup), and 146.52. For more information, send an SASE to ORARC Hamfest, Attn: Jim McNair N4EXG, PO Box 291, Oak Ridge TN 37830.

MADISON WI
APR 4

The Madison Area Repeater Association, Inc. (MARA), will hold its tenth annual Madison Swapfest on Sunday, April 4, 1982, at the Dane County Exposition Center Forum Building, Madison WI. Doors will open at 8:00 am for sellers and exhibitors and at 9:00 am for the public. Admission is $2.50 per person in advance and $3.00 at the door. Children twelve and under will be admitted free. Tables are $4.00 each in advance (early reservations are recommended) and $5.00 at the door. Features will include a flea market, commercial exhibitors, and door prizes, as well as an all-you-can-eat pancake breakfast and a bar-b-q lunch. There are hotel accommodations nearby and plenty of parking space. Talk-in on 146.16/.76 WR9ABT. For reservations or more information, write to MARA, PO Box 3403, Madison WI 53704.

GROSSE POINTE MI
APR 4

The Southeastern Michigan Amateur Radio Association (SEMARA) will hold its 24th annual hamfest swap and shop on April 4, 1982, from 8:00 am to 3:00 pm at the Grosse Pointe North High School, Vernier Road (between Mack and Lakeshore), Grosse Pointe MI. The admission charge is $1.00 in advance and $2.00 at the door. There will be good food, plenty of free parking, door prizes, cash prizes, and a grand prize drawing. Talk-in on 147.75/.15. For further information, please send an SASE to SEMARA Swap, PO Box 646, St. Clair Shores MI 48083, or phone Ray Ninness WD8KXN at (313)-777-0119.

FRAMINGHAM MA
APR 4

The Framingham Amateur Radio Association will hold its 6th annual spring flea market on Sunday, April 4, 1982, at the Framingham Police Station drill shed, Framingham MA. Admission is $2.00. Sellers' tables are $8.00 before March 27, and $10.00 after that date. Doors will open at 10:00 am but sellers may begin setting up at 8:30 am. Radio equipment, computer gear, food, and bargains will be available. Talk-in on .75/.15 and .52. For more information, contact Ron Egalka K1YHM, 3 Driscoll Drive, Framingham MA 01701, or phone (617)-877-4520.

SOMERSWORTH NH
APR 17

The Great Bay Radio Association will hold its 2nd annual Hamfest-Flea Market on Saturday, April 17, 1982, from 9:00 am to 3:00 pm at the Somersworth

Swap tables are $5.00 each day. Special rates are available at the Holiday Inn Southwest if you specify that you are attending the Jackson hamfest. There will be a hospitality room at the hotel Saturday night and food will be available at the hamfest both days. Talk-in on 146.16/.76, 146.52, and 3987.5. For swap-table reservations or further information, contact Don Elder KC5VD, 2806 N. Mill Street, Jackson MS 39216, or phone (601)-362-0336.

TRENTON NJ
APR 17-18

The 7th Trenton Computer Festival will be held on Saturday and Sunday, April 17-18, 1982, from 10:00 am to 5:00 pm at Trenton State College, Trenton NJ. Admission for all activities is $5.00. Student admission is $3.00. Features will include commercial exhibits, an electronics flea market, many technical sessions, and, on Sunday, free short courses. For further information write TCF-82, Trenton State College, Hillwood Lakes CN550, Trenton NJ 08625, or call (609)-771-2487.

PADUCAH KY
APR 18

The Paducah Amateur Radio Association Ham/Swap Fest will be held on April 18, 1982, from 9:00 am to 3:00 pm CST at the Paducah Jaycee Civic Center, Paducah KY. Admission is $1.00 and includes a free table. There will be net meetings and a flea market. Talk-in on 147.66/.06. For more information, contact Bruce Huyck WD4BVW, Rte. 8, Box 431, Paducah KY 42001, or phone (502)-444-7725.

SULLIVAN IL
APR 18

The 21st annual Moultrie Amateur Radio Klub Hamfest will be held on April 18, 1982, at the Moultrie County 4-H Center Fairgrounds, Caldwell Road, located 5 miles east of Sullivan IL. There will be a heated indoor flea market and a large, covered, outdoor flea market. There is no charge to vendors and space is on a first come, first served basis. Talk-in on 146.94 and 146.655/.055. For more information, write Ralph Zancha N9CDK, President, MARK, PO Box 55, Lovington IL 61937, or call (217)-873-5287.

RALEIGH NC
APR 18

The Raleigh Amateur Radio Society will hold its 10th annual hamfest on Sunday, April 18, 1982, from 8:00 am to 4:00 pm at the Crabtree Valley Shopping Center parking area, Raleigh NC. Admission is $4.00; there will be a table charge for exhibitors and flea market displays. First prize is a choice of a Kenwood TS-830S transceiver or an Icom IC-251A multi-mode 2m transceiver with a Mirage B108 80-Watt amplifier. A hospitality room and party will be held the preceding evening from 7:00 pm to 10:00 pm. Talk-in on 146.04/146.64 and 146.28/146.88 both days. For more information, please contact Ken Boggs KB4RV, 8704 Cliff Top Ct., Raleigh NC 27612, or phone (919)-782-8646.

DAYTON OH
APR 23

The 13th annual B•A•S•H will be held on Friday night, April 23, 1982, at the Dayton Hamvention at the Convention Center, Main and Fifth Streets, Dayton OH. Admission is free and parking is available in adjacent city garage. Live entertainment, sandwiches, snacks, and a COD bar will be available. Awards will include a new synthesized HT and a synthesized pocket scanner. For further information, contact the Miami Valley FM Association, PO Box 263, Dayton OH 45401.

SPOKANE WA
APR 24

The Inland Empire Amateur Clubs will hold the third annual Inland Empire Swap Fest on April 24, 1982, beginning at 9:00 am at the Spokane Interstate Fairgrounds, Broadway and Havana, Spokane WA. Admission is $1.00 and includes a special door prize raffle ticket. Regular raffle tickets are $.50. Activities include commercial and non-commercial displays, an auction, YL craft sales, a snack bar, a banquet at Roy's Chuckwagon, and a flea market. Tables (4' x 8') are $5.00 per full table and exhibit space is free. Talk-in on 146.34/.94 and 146.52. For reservations for tables, exhibit space, and/or a free RV site (without electrical hookup), write Swap Fest, c/o Jan Thiemann KA7DDV, 78033 E. Mission, Spokane WA 99206.

BEMIDJI MN
APR 24

The Bemidji Amateur Radio Club will hold a swapfest on Saturday, April 24, 1982, starting at 9:00 am at the Holiday Inn, Highway 2 west, Bemidji MN. There will be door prizes, refreshments, and plenty of free parking. For more information, contact Bill Williams WAØABX, Rte. 1, Box 369J-3, Bemidji MN 56601, or phone (218)-751-9070.

DIXON IL
APR 25

The Rock River Amateur Radio Club will hold the 16th annual hamfest on Sunday, April 25, 1982, at the Lee County 4-H Club Center, 1 mile east of the junction of Rtes. 52 and 30, south of Dixon IL. Advance tickets are a $2.00 donation; at the gate a $2.50 donation will be asked. Breakfast will be served from 6:30 am to 9:00 am and lunch will be served from 9:00 am on. The grand prize is $500

cash and the second prize is $200 cash. You need not be present to win these, but you must be present to win the hourly door prizes. Talk-in on 146.52. For advance tickets, write Ed Webb WD9CJB, 618 Orchard, Dixon IL 61021.

BRAINTREE MA
APR 25

The South Shore Amateur Radio Club of Braintree MA will hold an indoor flea market on Sunday, April 25, 1982, at the Viking Club, 410 Quincy Avenue, Braintree MA from 11:00 am to 4:00 pm. An entrance fee of $1.00 will include one chance for the door prizes. Additional chances are 3 for $1.00. Plenty of parking will be available. The Viking Club will be open for vendors at 10:00 am. Eight-foot tables will be available for $8.00 each and may be reserved in advance by sending a check payable to the South Shore Amateur Radio Club to Ed Doherty W1MPT, 236 Wildwood Avenue, Braintree MA 02184. For further information, call Ed at (617)-843-0510 or (617)-843-4431 (evenings).

LYNNFIELD MA
MAY 1

The Quannapowitt Radio Association (QRA) will hold an indoor/outdoor hamfest on Saturday, May 1, 1982, from 9:00 am to 4:00 pm at South Hall Fire Station, corner of Salem and Summer Streets, Lynnfield MA. Admission is $1.00 at the door. Reserved tables are $5.00; at the hamfest, $7.00. Food will be available. Talk-in on 146.19/.79 or .52. For additional details, write Dave Meldrum KA1M1, 28 Cedar Lane, North Andover MA 01845.

HAM HELP

Our club is in dire need of a service manual for a Johnson Thunderbolt linear amplifier, catalog # 240-353.

Ronald Daly WB9ZNI

Central Falls RI 02863

Flash and Crash 101

—how to weather the storm

Dave Malley K1NYK
132 Lydall
Manchester CT 06040

Lightning is one of the most common occurrences found in nature and certainly tends toward the spectacular. It is responsible for starting about 10,000 wilderness fires in this country each year and also infrequently causes deaths. Furthermore, there have been many misconceptions and superstitions invented over the years.

In spite of the losses that can be involved, the average person knows very little about this phenomenon. It would seem that hams in particular have something of a vested interest in knowing the facts so that the fate of their equipment will not be left completely up to chance. This article will deal both with how lightning occurs and the various protection methods that are available.

A lot of information has been obtained since Ben Franklin first tried to electrocute himself with his experiments about 200 years ago. Meteorological observations now have established thunderstorm activity levels on a worldwide basis. Fig. 1 shows that the annual number of these storms varies from single-digit numbers up to as high as 200 in parts of South America. Interestingly, the maximum activity occurs over land masses that are located close to the equator. This relationship to latitude mostly reflects increased evaporation and cloud formation in the hotter climates.

Similar data has been generated for thunderstorm frequencies encountered across the United States. South Florida has the distinction of having the highest annual activity—100 thunderstorm days. Fig. 2 shows the thunderstorm activity throughout our country and can be used as a partial guide for determining the typical frequency in your area.

The information presented in Figs. 1 and 2 shows the number of days that thunder was heard and does not tell whether a lightning flash goes to ground or is contained inside the cloud. Furthermore, the number of flashes to ground increases substantially with increasing distance *away* from the equator (Fig. 3). Severity of storms is not reflected by the data at all. (A more precise method might involve recording thunderstorm duration instead of just occurrence.) Consequently, these activity levels should be considered as relative information rather than absolute values.

The clouds that typically are responsible for thunderstorms and lightning are termed cumulonimbus. These so-called "thunderheads" are usually very large and reach overall heights of 35,000 feet. The temperature at the top of the cloud is a rather brisk −40° F. Such a cloud formation will spread out horizontally over several miles. Lest you think that lightning is produced only by thunderstorms, you might be interested to know that sever-

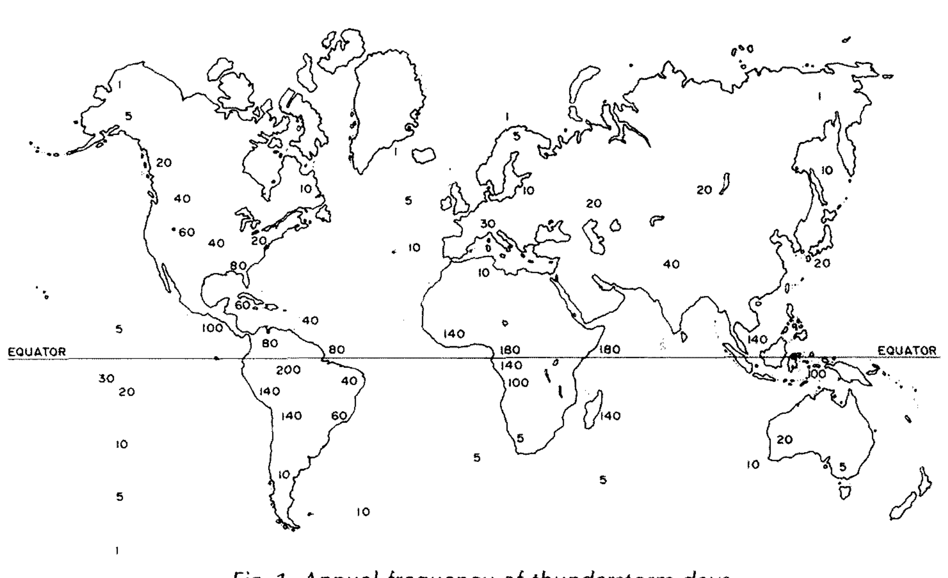

Fig. 1. Annual frequency of thunderstorm days.

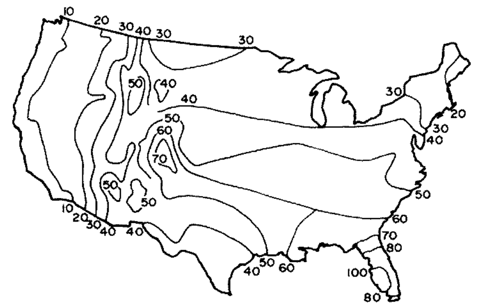

Fig. 2. Typical annual US frequency of thunderstorm days (Ref. 1).

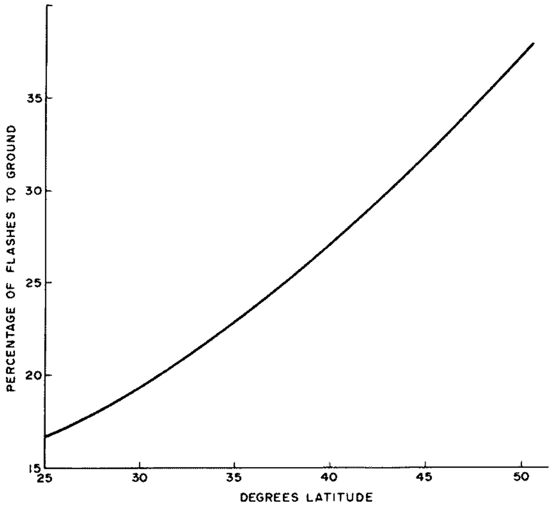

Fig. 3. Graph shows increasing probability of cloud-to-ground lightning strikes as distance from equator increases.

al other possibilities exist as well. These include: sandstorms, snowstorms, and clouds located over erupting volcanos (Reference 1). Lightning associated with snowstorms occurs often enough to be a concern to aircraft. Back on the ground, though, we will be interested in the common thunderstorms.

Contrary to widespread belief, lightning does not come instantly crashing down to the Earth whenever Zeus is angry. In fact, it does not always come *down*, but occasionally can extend up to the cloud. These items are in the folklore that we'll try to set straight. Lightning actually consists of several stages. These are: the leader, initial return stroke, residual decay current, and usually one or more restrikes (Reference 2). The high-current portion occurs in about 10-100 microseconds while the total cycle takes up to 0.25 seconds. The rate of propagation is something less than the speed of light because of inductance and capacitance effects along the path.

The source of energy that ultimately creates the discharge is presumed to be warm air rising toward the top of the cloud. The charging process in the cloud is thought to happen as a result of falling ice crystals. Portions of these crystals splinter off and become electrostatically charged. Wind currents then carry these positive charges up to the cloud's ceiling. The heavier remaining portions of the ice accumulate a negative charge at the bottom of the cloud.

Other theories also exist, but their common denominator is that the cloud contains one or more localized "cells" where the lower part of the cell is negative. Local potential differences can reach many millions of volts inside the cells. Relative to the Earth, the cell (cloud) has a net negative potential and a lifetime on the order of a half hour.

As the cloud comes overhead, the ground underneath it takes on a positive charge. Put more accurately, negative ions in the ground are repelled from the area directly under the cloud formation. When a vertical conductor (flagpole, tower, etc.) is present, an intense field concentration occurs at its tip which can exceed the breakdown (dielectric) strength of the air. This causes microampere "point-discharge" currents characterized by a bluish corona. Sailers used to call this corona St. Elmo's fire after a Mediterranean patron saint. Incidentally, this effect will cause severe local static. This is one reason why vertical antennas have a ball rather than a point at their tip. The ball's larger radius tends to reduce the possibility of corona discharges and their effects on reception.

Eventually, a column of ionized air called a pilot streamer reaches out from the cloud toward the ground. Afterwards, a more intense discharge takes place in the form of a series of incremental steps. This is referred to as the step-leader. This leader and its branches bring the negative cloud potential closer to the Earth—reduce the spark gap, if you will.

Earlier, it was noted that leaders occasionally start from the ground and nearly reach up to the cloud. Fig. 4 shows that fewer than 5% of the leaders associated with a 100-foot tower will behave like this. In all lightning discharges, however, short streamers extend upward from the object just before the discharge. This is the same phenomenon as St. Elmo's fire. When the two streamers connect, they provide a highly conducting path (filament) which allows the charge in the tip of the leader to flow to the ground.

As this current becomes higher, the filament impedance is reduced and more current flows. This reduces the charge at the leader's tip, allowing the conducting arc to reach higher up into the filament channel. Consequently, this arc propagates *up* to the cloud and is called the return stroke. The speed of this return stroke is much faster than the step-leader that was "feeling" its way down to Earth. However, the overall speed of propagation is only about one-third that of the speed of light.

Generally, people are not aware of this return stroke. However, this is what actually produces the bright lightning flash as well as the thunder. The light involved is simply a result of the arc itself, while the high currents result in rapid expansion of the surrounding air. This causes the thunderclap. An old rule of thumb says that your distance from the spot where the lightning struck, measured in miles, is equal to the number of seconds between the flash and the thunder.

The currents flowing during the return stroke average about 25,000 Amperes. Currents above 150k Amps have been recorded, but those over 80,000 Amps are rare. By comparison, the step-leader currents typically are in the tens or hundreds of Amperes. The high-current values are measured indirectly as you

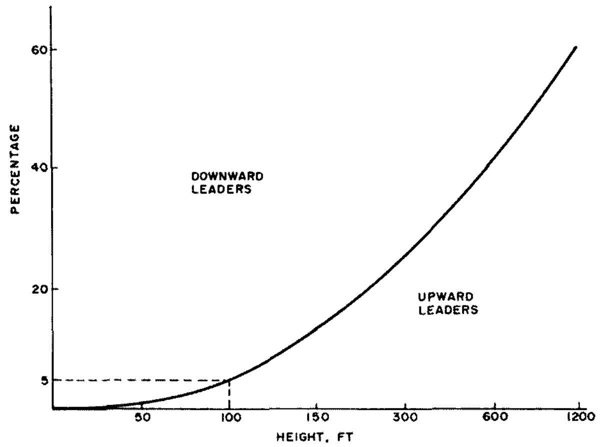

Fig. 4. Percentage of upward leaders is slight without very tall structures.

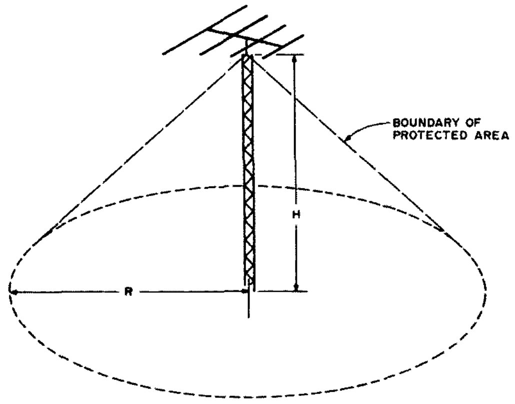

Fig. 5. Sketch showing principle of protective cone where the radius (R) at protective area (dotted) is equal to the tower height (H).

might imagine. Originally, small bundles of steel strips called magnetic links were placed perpendicularly near whatever was expected to be hit. Any eventual lightning current would magnetize the links, and the amount and direction of the current flow could be deduced. Recently, similar methods have used magnetic recording tape where the strike partially erases a pre-recorded signal of known strength. Again, the current would then be calculated.

The final phase in the overall lightning process consists of a low-level continuing current which provides the opportunity for at least one more immediate restrike. This usually happens about 200 millseconds (0.200 sec.) after the initial strike. This additional discharge invariably hits the same point on the Earth as its predecessors. This fact alone indicates that lightning can strike the same spot more than once.

Several factors can increase the probability of a building, tower, or whatever being struck. Geographic effects were mentioned earlier. Most of the others are not surprising. The type of terrain is important, with the valleys being struck less often than higher elevations. For a given location, the possibilities increase as the square of the height of objects above ground.

Grounding a tower will help reduce the amount of electrostatic charge present. This can help avoid a strike since the field strength at the top of the tower will be considerably lower, and upward streamers will find it that much harder to form. More important, though, the good ground will allow the current to be safely discharged into the ground.

Another factor is that the tower (or highest object) creates a so-called cone-of-protection which protects. other structures inside this cone. An example of this could be your house. The actual area protected is not well established, although a conservative figure seems to be that the radius of the cone is equal to the tower height (Fig. 5).

There are quite a number of ways to increase the protection of your equipment during a thunderstorm without going broke in the process. However, you should realize that there is no absolute protection short of tossing all transmission lines, rotor cables, etc., out of the window and unplugging the radio. (Even this assumes that you thought to take action well ahead of the storm and were at home to do so. Do not disconnect these cables just before the storm or when it is in progress.) Fortunately, there are some things that can be done that don't require you to be a recluse in the house.

The first major step is to provide all of the station equipment with a good earth ground. This means that all equipment in the house should be attached (bonded) to an outside ground rod using as short a length of heavy wire as possible. The standard rod is a 0.5-inch copper bar driven eight feet into the ground. This provides a low-impedance path. Experiments have shown that larger diameters or greater depths do not provide better performance. These rods can be bought from local electrical supply houses.

You should avoid copper-plated steel bars because the plating will wear or corrode off leaving a rusty ground rod. There goes any low impedance! Simply check your ground rod to make sure it is not magnetic. If it is really necessary to ground to a water pipe in the house, use a cold water pipe since corrosion can break the electrical continuity of the hot water ones. Also, check to see that the water meter has been bridged with a heavy wire.

At least two of the tower legs should be attached to individual ground rods. These should be driven into the ground rather than through the concrete and into the ground. The same store that carries the rods usually also will stock brass clamps to secure the wires to the tower and the ground stakes. Remember to similarly treat any guy wires. Copper is best for the ground wires, but if aluminum is used, it should be about a #2 size. Don't run aluminum through the concrete since corrosion will ruin the wire in short order.

The wires to each rod should be short and as direct as possible with no kinks or sharp bends. Lightning does not want to turn corners! No ground wire should be placed through a metal conduit. This setup would act as an rf choke and encourage the lightning to find an alternate route. If you are compelled to be neat, use porcelain or some other non-metallic material for the pass-through.

Methods also are available to reduce the risks of strikes to antennas. Again, bleeding off electrostatic-charge buildups caused by rain and snow is helpful. Some antennas such as ground-mounted verticals and beta-matched beams

are already at ground potential and require no further attention in this regard. If this is not the case and coaxial feedlines are used, a device such as Cushcraft's Blitz-Bug can be inserted in the coax near ground level where its case can be grounded. This device contains a built-in spark gap that will bleed off excess charges to ground.

There are other tricks that can be used with coax, also. I made several one-foot diameter turns in the coax at the base of the tower. This took up excess cable lengths and also provided an rf choke to help discourage the lightning from entering the house. A right-angle turn right after the choke arrangement performs similarly. Compared to your transceiver, the price of new coax is cheap!

When the station is not being used, the antenna switch should be turned to its ground position. Since extended inactivity periods occur with vacations, etc., it is convenient to homebrew a coax grounding box which is mounted to the tower or to a ground stake. Such a device is shown in Fig. 6.

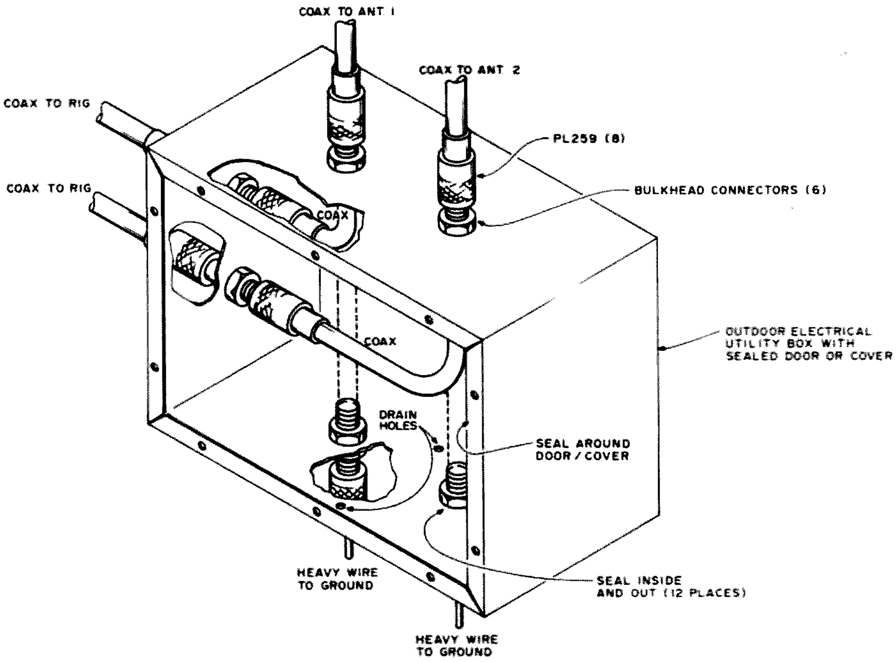

Fig. 6. Sketch showing grounding box configuration for coaxially-fed antennas.

An outdoor utility box with a hinged or removable cover and a good weather-tight seal forms the basis of the unit. Three male-male coaxial feedthrough connectors (UG363) are needed for each coaxially-fed antenna. Inside the box there is a short length of coax with PL-259 connectors attached to each end. One of the groups of three feedthough (bulkhead) connectors is located in the bottom of the box and its center conductor is grounded.

During normal use, a patch cord is connected directly from the antenna to the coax running to the radio. However, before the vacation, this patch cord is changed over to the grounded connector. This grounds the antenna directly and essentially eliminates the chance of a direct hit from entering the house via the coax lines. Remember to be sure to seal the holes around each connector mounted on the box. Silicone rubber, RV, or other compounds can be used effectively for this purpose. It is a good idea to drill one or two small holes (1/16-1/8 inch) in the bottom of the box to allow for condensate drainage.

If your station uses an open-wire transmission line, the above suggestions are not appropriate without some modification. However, this situation was covered long before we started using coax. The time-proven method of protecting gear in this case is to use an air gap (Fig. 7). The gap distance is chosen to be too large for the signal to bridge but small enough to allow lightning to jump across it and continue on to ground. Various handbooks deal with these air gaps in detail, and various things including spark plugs have been used.

In the potpourri department, a comment or two come to mind regarding roof-mounted VHF/UHF antennas and even the TV ones as well. Most people are aware that the mast that supports these antennas should be grounded. A typical installation involves bringing the transmission line, rotor cable, and the ground wire down the side of the house in a neat parallel manner. Electrically, though, it is not so pleasing. In the event of an actual strike, the lightning has a choice of paths to ground. Side flashes from the ground wire to one of the other cables is also possible. This problem can be overcome by making sure that the ground wire is the shortest and placing the other wires away from it. Again, we see the rule of thumb regarding short, direct ground wires coming into play.

One should realize that damage to electronic equipment does not necessarily require a direct lightning strike. Relatively large voltages (spikes) can be in-

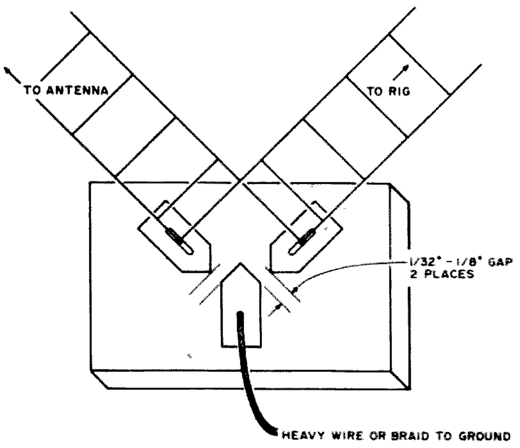

Fig. 7. One of several spark-gap methods used to protect open-wire-fed equipment.

duced into the ac distribution system when a neighborhood utility pole is hit. The voltage transients produced can travel into equipment via the house wiring. An obvious solution is to pull the plug, but this is not always convenient and can be forgotten. Protection against these spikes is especially important with solid-state rigs since they do not have the overvoltage capabilities of their tube predecessors. Fortunately, help is available in the form of a voltage-spike-protector device. This unit can be attached to essentially any transformer-type ac equipment. The device is a metal-oxide varistor sold by General Electric (Model GE-MOV) and others. The varistor is a two-lead unit that is attached across the transformer primary winding and breaks down to a low resistance in the presence of a large-surge voltage. The action happens very quickly (several microseconds) and shunts the spike across the transformer primary and prevents damage from occuring.

A Closing Note

Well, there you have the basics of how lightning develops and what can be done to minimize its occurrence and effects. Total protection cannot be ensured unless each piece of equipment is isolated from the antenna and the ac mains. Unfortunately, this is not always possible. However, the techniques presented in this article are simple to apply and will provide a significant measure of protection for your equipment. ■

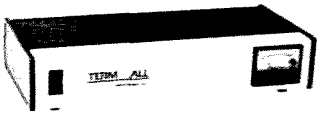
apple* TERMINALL

$499.00



Simplicity of Operation — Superior Performance
What are you waiting for? THIS IS THE WAY TO GO

TERMINALL now available for APPLE II ! TERMINALL T2 is a hardware and software system which converts your Apple II computer into a state of the art communications terminal. Simply insert the interface card into any available card slot (1-7) in your APPLE, then plug the attached cables into your radio.

Simplicity. TERMINALL was designed from the outset to be easy to connect to your radio and easy to use. Plug into your receiver headphone jack and copy Morse Code or radioteletype (RTTY). Plug into your CW key jack and send Morse Code. Attach a microphone connector and send Baudot or ASCII RTTY using audio tones (AFSK). That's all there is to hooking it up.

Complete software on DOS 3.2 diskette (Muffin to 3.3), assembled and tested hardware, and extensive instruction manual. Requires an APPLE II or APPLE II Plus, 48K and disk.

THE COMMUNICATIONS TERMINAL THAT DOES IT ALL!

The software is loaded into your computer from disk. Enter your callsign and the time and you will start receiving immediately. No settings or adjustments are necessary to receive Morse Code. It's fully automatic (and it works)! You may type your message while receiving or transmitting. You will be on the air receiving and transmitting in any mode in minutes. As we said, TERMINALL is simple.

- ■ TERMINALL has the RTTY terminal unit (demod and AFSK) built in. This results in a lower total cost.
- ■ **Fantastic Morse reception.** Six stage active filter demodulator copies the weak ones. Auto adaptive Morse algorithm copies the sloppy ones. Received code speed displayed on status line.
- ■ **Outstanding documentation.** Professionally written 90 page user manual contains step by step instructions.
- ■ **Built in separate multi stage active filter RTTY and CW demodulators.** No phase lock loops. RTTY demodulator has 170 and either 425 or 850 Hz shift (keyboard selectable) and uses either the panel meter or scope outputs for easy tuning. Copy the weak ones. Copy the noisy ones. Copy the fading ones.
- ■ **Built in crystal controlled AFSK.** Rock stable for even the most demanding VHF or HF applications. A must on many VHF RTTY repeaters.
- ■ **Built in 110 or 220** volt AC power supply.
- ■ **Built in parallel printer driver software.** Simply attach a parallel ASCII printer (e.g. the EPSON MX 80) to your printer port to obtain hardcopy in all modes.
- ■ **Multi level displays** allows examining and editing of historical text. Word wrapping, word mode editing, diddle, ignore carriage returns, user programmable end of line sequence, adjustable carriage width, multi user defined WRU, transmit delay (fixed, none or auto adaptive), break mode and more.
- ■ **The all-in-one TERMINALL** design makes it great for use on HF or VHF Ham, Commercial, SWL or MARS! SWL's TERMINALL may be jumpered for either 425 or 850 Hz reception to copy news and weather services.

Stormy Weather

—to be forewarned is to be forearmed

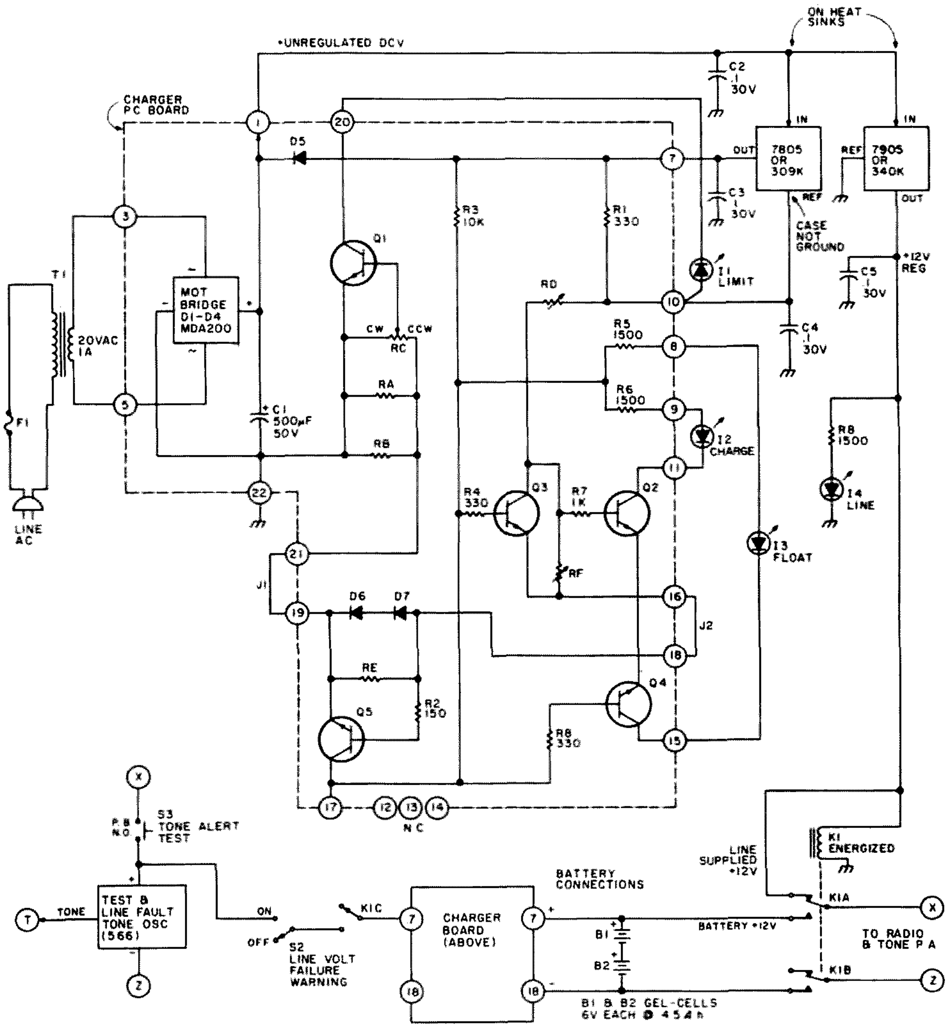

Fig. 1. Power pack: ac operation, dc battery and charging, and the automatic switching between ac and dc.

David J. Brown W9CGI
RR 5, Box 39
Noblesville IN 46060

You say the storm just turned your yard and basement into Lake Michigan? The swing set just tipped over into your picture window, and the St. Bernard got blown halfway through the fence—what's left of it? Is there something going 'round and 'round and marching down your street with your nice new car bouncing along on its top? Is that what's troubling you, Bunky?

The heavens truly opened up and delivered their wrath, but at least you and the family all made it through in one piece! Or maybe you have seen it happen to others, and it just came too close to you for comfort. Well, then, have I got something for you! No longer do you have to keep one eye on the sky, one foot in the basement, one hand on the most valuable thing you own, an ear screwed into the radio, and then still try to work and go around and about your business in that position. That is like the old shoulder to the

wheel, eye on the ball, etc., and-try-to-work-in-that-position joke. Why not let a very special monitor do the worry and watching, courtesy of the National Weather Service VHF radio broadcasts?

Should the "very special" comment lead you to believe my idea is also quite expensive like the special receivers used in schools for weather warnings, don't let it! It is just not true. The "special" refers to the dedicated and reliable job my unit does and some of the easy and inexpensive ways to accomplish really fantastic results.

The Source of Warning

The National Weather Service operates a weather-warning system of VHF stations throughout the country. They are located in nearly every major-size city, near any sizable body of water, and in some remote places you would never believe. A phone call to your local radio/TV station, a note to the National Weather Service (NWS), or punching up their frequency on a monitor will tell you quickly if one is nearby enough for you to use it. The frequencies in use are 162.400, 162.475, and 162.550 MHz, one frequency to any given area.

Our station in the Indianapolis area is on 162.550 MHz and serves a much wider territory of central Indiana than I think even NWS planned on. The transmissions are narrowband FM (approximately 5 to 7 kHz audio) and easily programmed into most of the available monitor/scanners.

A word about scanners, though. I have had Indy NWS programmed into my Bearcat 250 scanner since I first learned of it. I live on a farm, out in the open, and am, in a word, vulnerable! However, if you want the scanner to still scan, you must lock out the NWS channel except when you want to listen to it. Unfortunately, with it locked out, you may miss a weather alert/warning call when you need it most. You could be asleep, scanning 2m or the police, etc. I am not knocking a scanner or monitor for occasional NWS channel use, but to tie one up on it for serious warning and safety use is an expensive and silly approach.

Storms come up far too fast in the southwest and midwest, unlike, say, a hurricane approaching Florida or Texas. There were days of warning on recent hurricanes. In the midwest, when two air masses get together, we often get some hair-raising *minutes* of a tornado warning.

Solutions—Save Our Souls (. . . — — — . . .)

There are, fortunately, several answers to the problem. Proper equipment choice, the way NWS handles real alert conditions, and what you may already have on hand or be able to get cheap are all that I want to tie together in this article.

First, the service was not chosen in the 162-MHz region arbitrarily. It was originally a marine weather service and that fits the frequency range of most of the marine VHF radios nicely. To be useful, it is a 24-hours-a-day, 7-days-a-week continuous broadcast of weather and related information to serve those marine commercial and private boat owner/operators.

Downtime is for fixing a failure or preventative maintenance only, and most stations, if not all by now, have back-up gear to cover those times when the main transmitter is off the air. There is *no* receiving on those frequencies by NWS,

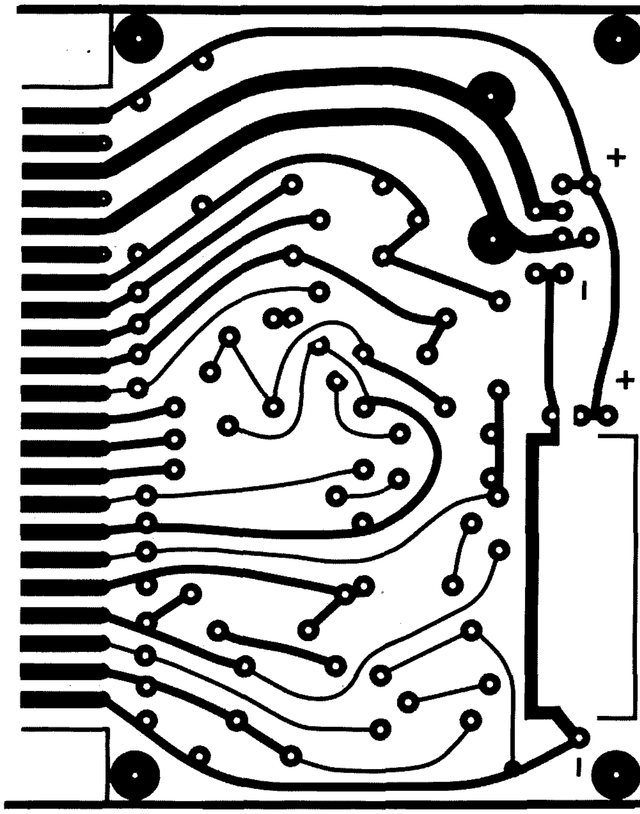

Fig. 2. PC board layout for power source.

and *please* do not transmit anything there! When a real danger exists in the station's area or approaching it, such as severe storms or a tornado watch or warning, the NWS station comes on with a live broadcast immediately.

These "alert" broadcasts are preceded by 15 to 20 seconds of continuous 1050-Hz audio tone. That is the trick to making my receiver idea work, without going insane listening to the all-day and all-night-long broadcasts. They are loop-taped, about 1 minute long, and updated about once per hour or as needed. Over and over, and believe me, it goes on, and on, and on! You could become an NWS announcer word-for-word after about 10 passes of that same information.

Since they use that 1050-Hz tone before every live broadcast of an "alert/warning" nature, I decided to detect it, open a receiver's audio and find out what all the commotion was about, and still not turn into a babbling idiot! So can you, and very inexpensively these days. I have shown and will explain in detail several ways to go about doing this from several different approaches. Then you can have your very own protection and enjoy a valuable and free service. This is not like snitching the HBO or cable services. NWS *wants* you to use this service. You could end up saving property damage to yourself and others, lessen personal injuries caused by these storms, and quite realistically protect life itself—and it could be your own. An ounce of prevention—a minute of warning—same story!

Power Sources

I have outlined a way to

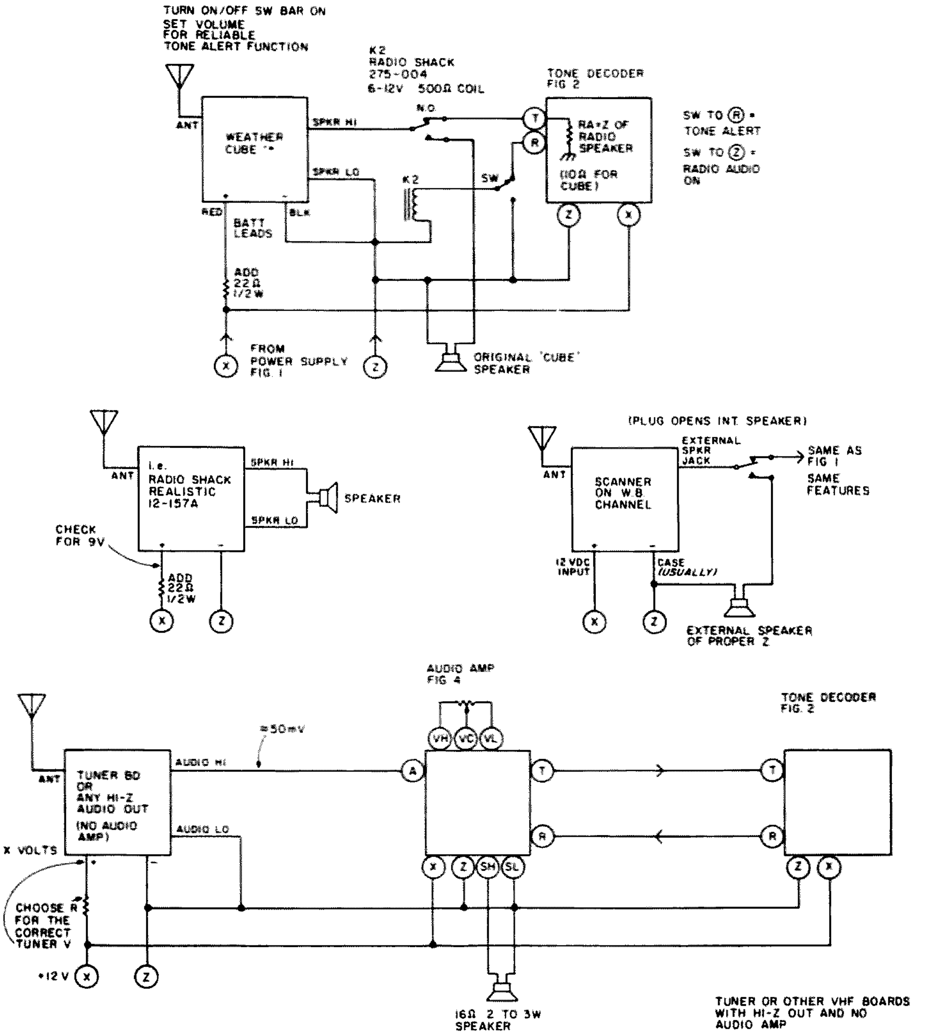

Fig. 3. Configurations: What can be put into service, uses, facts, and ideas. Configuration 1: Low-Z (speaker) radio audio, tone-alert feature, and power line failure feature. Configuration 2: Low-Z (speaker) radio audio, tone-alert built into radio, and power line failure feature. Configuration 3: Scanner use, e.g., Bearcat 101 or 250. Configuration 4: Tuner or other VHF boards with high-Z out and no audio amp. Configuration 5: Can be used like configurations 1 or 3 with 2m FM rig to monitor for tone calls only. Configuration 6: Same as 5, only WWV Time-cube and the tones given on the hour/half-hour/minute for contest or schedule operations. Configuration 7: Same as 5, with converted CB radio on 10m for local net or rag-chew call-up or messages. Configuration 8: Same as 5, with unconverted CB and emergency call-up, e.g., REACT, WTHR, disaster.

be warned of danger, but the danger is storms and with that goes wind, hail, ice, snow, tornadoes—and sooner or later loss of power from the ac mains. If lightning knocks a pole down up the road and your power goes off at the leading edge of the storm, and *then* the tornado comes dancing up to your doorstep, the alert monitor is not going to warn anybody with the juice off!

Any really useful monitor *must* have a standby power source and switch to it automatically. It should use rechargeable, rugged, sealed batteries like those I have shown as Gel/Cells in Fig. 1, B1 and B2. This figure describes my power system and the switching needed. I admittedly overkilled when it came to the Amp-hour rating and capacity of the batteries I used. I wanted to be sure if the power went off in the early evening, without having to forever eagle-eye the monitor, it would continue running on batteries—for days if need be. Further, a 12-volt jack on the back connected across (x) and (z) allows me to run the Bearcat 250 on 12 V dc all the time, by using the Bearcat mobile power input connection. In a real bind, I can even plug in my HW-202 2m FM rig with rubber ducky for full 2m operation. Note: The regulator supplying point (x) will *not* supply the Heathkit 2-Ampere transmit load when the power source is operational in ac mode, but then I have a Heathkit ac power pack for that. I am referring to real emergency conditions and battery operation only. The source in ac mode (point x) will supply 1 Ampere maximum.

In order to get the project into use as quickly as possible, I have "borrowed" heavily on others' designs that I knew worked. I have added a PC board if they did not, modified some circuits to do my bidding instead of the original author's, and created a lash-up that works and works well. I will try to credit the original authors and sources as I come to them, and I will point out my changes.

For opening credits, the battery charger complete with a very nice floating charge system for always live batteries is courtesy of Don Johnson WB6MXD via *73 Magazine*, August, 1980. I have had my alert monitor system for some time now, but the change to Don's system with float feature has really added dimension to it. It made good sense and worked right off, but it had no PC board. I added that as a plug-in or wire-in PC board and it is Fig. 2.

The batteries, as I said, are much more capable than the monitor requires. There is another good reason for staying with all that "grunt" capability, and that is that the batteries are readily available in the form of the replacement batteries for portable TV sets. One such source is RCA dealers or their Parts and Accessories Department (RCA part number 1437888-501—one 6-volt pack, i.e., B1 or B2). 12 volts requires two of these packs.

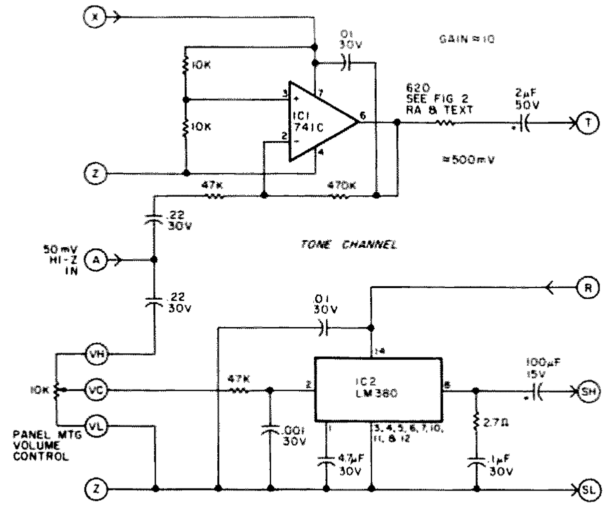

Fig. 4. Audio amplifiers: Using the total unit with tuners that have high-Z audio available and/or no audio output stage(s) to boost audio level for speaker.

It is a plastic package containing 3 cells, has leads of about 6" coming out with a rather standard molex™ 2-pin connector termination (male plugs, female pins), and the leads are long enough to change to any connector of your choice. For information sake, they are made by Gates Battery so their brand name 6 V @ 4.5 Ah will do fine also. The Globe-Union #1245 also is the same.

Control and Switching

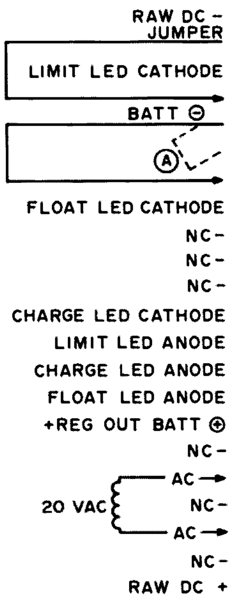
Fig. 1 shows all the switching to automatically drop the monitor to battery upon an ac line failure, sound a 1050-Hz tone and bring up the NWS audio if desired, and even automatically switch back to the ac mains when power has been restored. At that time the batteries begin recharging, and when back up to full charge, switch to the floating charge state to maintain full capacity for the next downtime failure.

LED indicators keep you constantly aware of status, so I recommend you mount them on the front panel with the speaker and volume control. The NWS-ON/Alert position switch can go there or on the rear panel, as you choose. After the tone brings up receiver audio for a fixed period, to go on listening, that switch must be changed from the normal alert monitor position to NWS, so act accordingly with your layout. My LED recommendations are: red for I1 to show limit current, yellow or amber for I2 to show normal charging, green for I3 to show the float/standby condition, and whatever fourth color you can come up with for the remaining I4 to show that the monitor is on and in the ac mode.

All circuits (LED, relay, audio, etc.) are arranged to allow minimum current drain in the battery service mode, i.e., all LEDs are off, relay K1 is de-energized, and audio is off until alert tone is received unless in NWS position. I have changed very little of Fig. 1 from Don's original except the added 12-V dc regulator as an ac-mode power source and switching relay K1. If you do not want the tone warning on ac failure but only for the radio to go on quietly monitoring NWS on battery power, K1 can be just a DPDT relay with a 12-V dc coil, no K1c contacts, and K1a and K1b contacts rated at 1 Ampere. S2 (warning on/off) can then be eliminated. I would advise you to wire it in and just put it to "off"; adding it costs so little. You won't know how useful it is until you have tried it for awhile. In any case, keep the alert test switch, S3, as you still want to be able to test the tone-alert system from time to time with an internal 1050-Hz tone. 20 seconds or so on S3 should open up receiver audio, whether the NWS carrier is present or not.

Automation—The Tone Decoder

This circuit is also borrowed, though modified, and belongs to Robert Lloyd, from *Popular Electronics*, May, 1976 (I read 'em all!). The original cir-



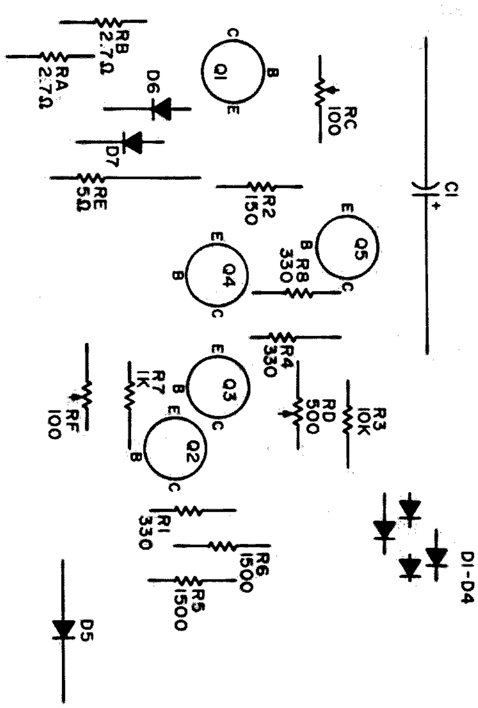


Fig. 5. Component location for power supply board.

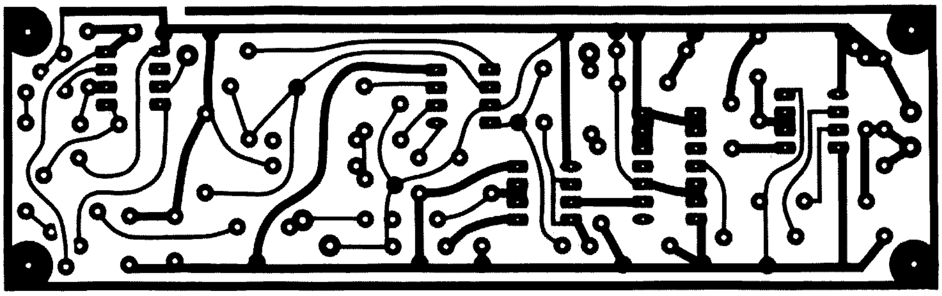

Fig. 6. PC board layout for tone decoder/tone oscillator.

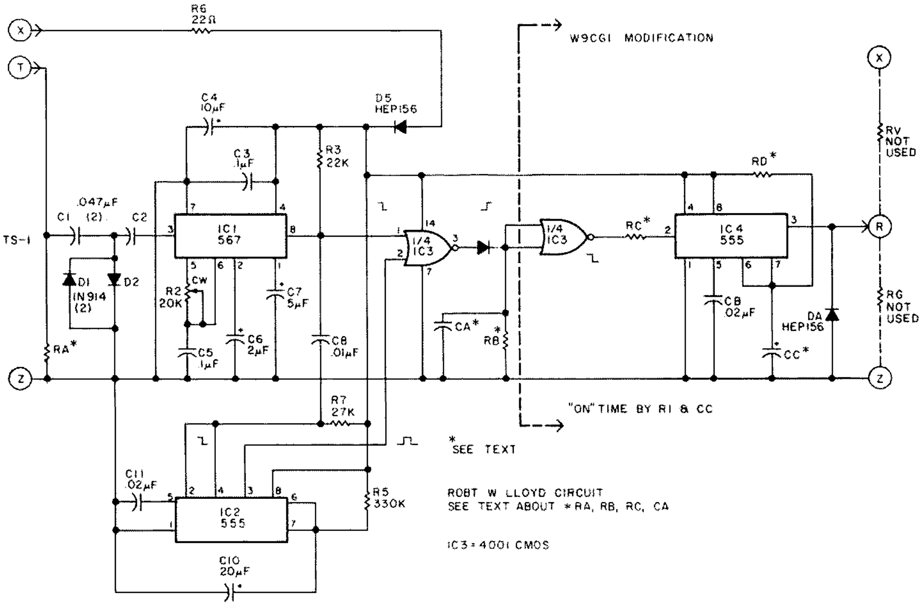

Fig. 7. Tone decoder and latch: Detecting the National Weather Service alert tone and holding audio on for a fixed period.

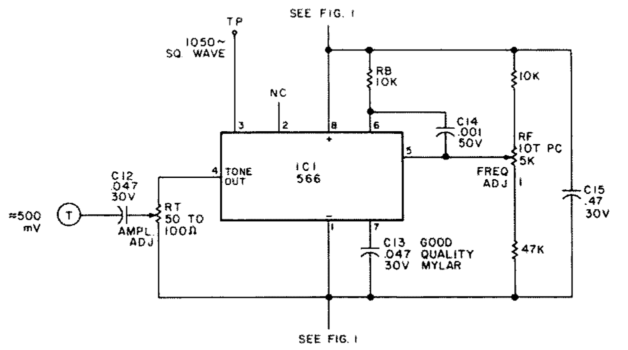

Fig. 8. Tone oscillator: Testing the tone alert and tone source for alerting the user of an ac failure.

cuit ran a 567 IC as the tone decoder, a 555 IC as an anti-falsing device to keep voice in the 1050-Hz range from triggering the monitor audio on, and ¼ of a CMOS 4001 gate to identify the legitimate over-15-second tone by gating the tone decode output (low) and the 555 output (returning to low) to form a high output. Mine is the same up to this point, except Ra is shown as an (*). For the Weather-cube™ used with Lloyd's original circuit (Fig. 3, Configuration 1), Ra is 10 Ohms. You will see more in the rest of the configurations for Ra values, but in general, Ra should be equal to the radio's speaker impedance or close to it. Usually from 10 to 47 Ohms works just fine, but try to match speaker Z. If Fig. 4 is used in any configuration, then Ra should be 600 to 620 Ohms to match the tone preamp's output impedance. There was no PC layout with the original on this one either, so I have included mine as Fig. 6. Fig. 6 also has the tone oscillator on it, since one feeds the other anyway, and that makes one less wire for you to hook up.

The modifications did *not* come about from Lloyd's circuit not working— it does. I simply could not locate quickly enough the HEP 320 SCR he used to latch things on after the tone is decoded. My substitutes were not reliable enough, and while mumbling something about local parts suppliers' relationships to the old 4-legged Army pack transportation, I decided I needed one more feature not provided for in his original circuit. Even had I gotten everything working up to here, I had overlooked one small detail in the NWS signal format and schedule.

Remember, I wanted *total* hands-off operation until the real tone alert brought things up. Well, as an added service to the schools and other NWS users, NWS also sends out a *test* tone callup every morning around 10 or 11 o'clock! That meant my perfect system would come on every morning and "serenade" my wife for 8 solid hours until I got home around 6 pm. You know by now, that even if she unplugged it, it would harp on and on. Since I don't wear a hat, my head goes in the door first, and I have grown rather fond of it staying attached to the rest of my body. 'Nuff said!

Building It My Way

Instead of the SCR to latch the system on, I have used another 555 IC set for about 2 minutes. I used another of the 3/4-unused gates in the 4001 to invert the original high-going SCR turn-on pulse to a low-going 555 trigger pulse. Now the monitor comes on for about 2 minutes. If anything interesting is going on, I can throw the switch from alert to NWS-ON and listen for any period of time, returning it to alert when I have finished. This way, even the test alerts only bring the monitor on for 2 minutes, and that I deemed tolerable. My head was safe again!

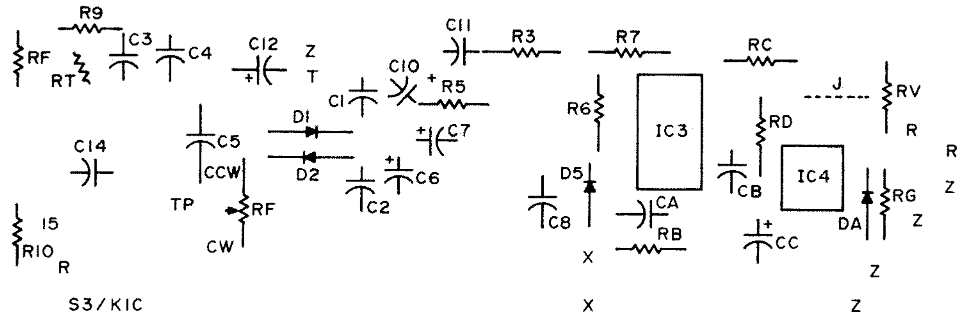

Fig. 9. Component location for tone decoder/tone oscillator board.

As for the further "see text" items indicated by *, Rc can be from 10k to 1M and still trigger the 555 and not injure the trigger input. It is a safety device to protect the 555 trigger input from attaching directly to the +V rail when high, as the CMOS 4001 device would allow it to do. Keep going up to 1M (or it quits triggering), cut that value in half, and you should be in fine shape from both safety and reliability standpoints.

Ca can be about the original 0.1 uF/30 V, and Rb should start at the original 470 point. Rb and Ca filter out the little glitch that occurs when the 567 tone decoder output goes low on tone. That low causes the 555 anti-falsing device output to go high, but not immediately. That instant that the 567 and 555 outputs are both low would make gate 1 output high, gate 2 output (inverter) low, and falsely trigger the last latch 555 on—a no-no. As long as the filter is big enough to stop that false triggering and not exceed the total normal tone duration, it will do. It is not critical, so try what you have.

Testing—The Tone-Osciilator Function

The tone oscillator is also borrowed, straight from a National Semiconductor Data Manual, June, 1973, for a 566 tone-oscillator IC. The PC layout is mine and is just added onto the input end of the decoder board, Fig. 6, as that's where its output goes, anyway. It is turned on by turning the voltage on and off, either by manual test by pushing the switch (Tone Alert Test, S3, Fig. 1), or by the K1c relay contact to alert you of an ac line failure. The switch, S2, between K1c and the tone oscillator merely lets you include the loss-of-mains feature, but not always use it if you so desire. Don't let the voltage on/off control of the oscillator scare you. Under normal circumstances it is not good practice, but it allows easier control switching here. The monitor tone decoder needs 15 or so seconds to respond, and the oscillator will settle down to its 1050-Hz output in much less than that.

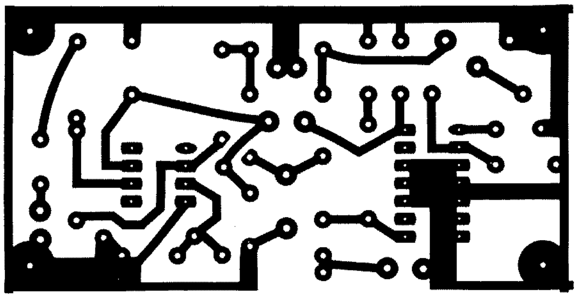

Fig. 10. PC board layout for audio interface.

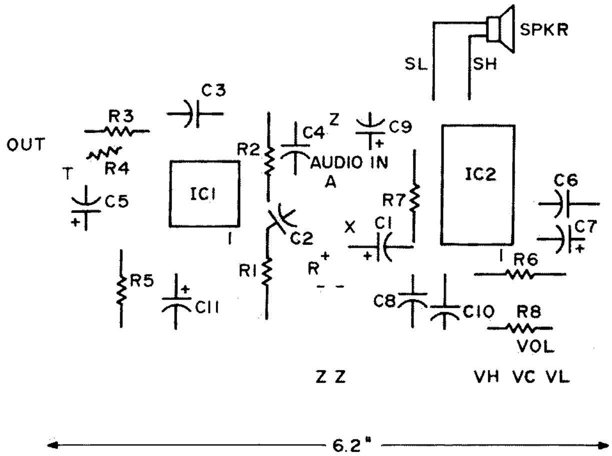

Fig. 11. Component location for audio interface board.

Interface—Making What You Have Work

Fig. 4 is a 2-channel audio circuit, and Fig. 6 is a PC layout for same. It too is "borrowed" from a friend at work, but it is pretty much two data-book circuits on a single PC board. The original intent was to build up the audio from a High-Z source, like a one-IC FM demodulator. One channel (the 741C) builds it up from 50 mV to 500 mV with a 600-Ohm impedance to drive a modulator like that used in a video tape or games unit. The second channel (LM380) builds the power level up to 2 to 3 Watts to drive a speaker. It was ideal for my purpose, and by a minor PC board change to divide the +12-V dc feedpoint into two points, it is perfect. The +12 V dc must go from power source (x) to the (x) of the audio board directly, so the tone amp is always on and working (741C). To silence the audio output without having to resort to things like breaking the poshi lead of the speaker with a relay (see Fig. 3, Configuration 1, relay K2), the +12 V dc to the audio amp (380) is broken instead. This is done by connecting power source (x) to audio board (R). Just when and how this is done is covered in the Configurations section and Fig. 3.

Configurations—Endless Ideas

Obviously, there are many ways to attack the problem once past the highly recommended Fig. 1 power source. The first step is what you are going to use to get the VHF down to audio—the monitor radio part. I have a few tips on that part that can save bucks.

First, don't overlook where you are and where the station is. A nearby station does not take a $300 receiver sensitivity to hear it. Even if you are a bit out from the station, don't overlook using "cropped-down" channel 2 through 6 VHF TV antennas of the discount store variety or a cropped-down broadcast FM or even 2m antenna.

ALIGNMENT and ADJUSTMENT

See the power supply in Fig. 1. With no battery attached, adjust R2 for the floating voltage of 13.5 V dc (2.25 volts/cell × 6 cells = 13.5 volts). Next, adjust the full-charge voltage by jumpering point A to the emitter of Q3 and adjusting R3 for an output voltage of 14.4 V dc (2.4 volts/cell × 6 cells = 14.4 V.

The current limit control, R 4, is a little more difficult to set. I set the control to full counterclockwise, then connected the battery, with an ammeter in series with the battery, to the charger. A partially discharged Gel/Cell will draw in excess of the maximum allowable charge current from an unregulated supply, so all you need to do is turn the limit control until the meter indicates 700 mA.

The charger is ready for service. Connect the Gel/Cell and watch the lights. The yellow LED indicates the battery is charging. If the red LED also is on, you know that the charger is limiting and you can expect the terminal voltage to be below 14.4 volts. As the fully-charged condition nears, the red LED will go out and the voltage will reach 14.4 volts. When full charge is reached (charge current below 100 mA), the yellow LED will go out as the green one comes on.

No alignment or adjustment is required for the audio interface in Fig. 4 beyond setting the user (panel-mounted) volume control for the volume level you want.

See Fig. 7, the tone decoder. For testing, start with the ICs out and the circuit not connected to the receiver.

Install *IC1* in its socket and connect a dc voltmeter between pin 8 and ground (positive side to pin 8). Turn on the dc power and note that the voltmeter indicates close to the supply voltage. Connect an audio signal generator ground to the circuit ground and the hot side to the W terminal of *TS1*. With the relay de-energized, IC1's input should now have a signal.

Set the signal generator as close as possible to 1050 Hz. Adjust *R2* until the voltmeter reading drops to near zero, indicating that *IC1* is decoding. Remove the signal generator and the voltmeter should go back to the supply voltage reading. Perform this step several times to make sure that *IC1* is operating with each application of 1050 Hz. Turn off the audio generator and the dc power.

Remove *IC1* from its socket and install *IC2* in its socket. Connect the dc voltmeter between pin 3 of *IC2* and ground. Turn on the dc power. Connect a jumper to circuit ground and touch the other end to pin 2 of *IC2*. Note that the voltmeter reading is the supply voltage. After about 10 seconds, the voltmeter should drop back to near zero, indicating that *IC2* has timed out. If the timing is too short, increase the value of *R5*. Conversely, if it is too long, reduce the value of *R5*. Check the timing cycle several times to make sure it is in a range of 7 to 14 seconds. Turn off the power supply and remove the jumper.

Remove *IC2* from its socket and install *IC3* in its socket. Connect one end of a jumper to circuit ground and the other end to pins 1 and 2 of *IC3* simultaneously. Relay *K1* should close and lock in. Wait for l4 time-out, and note that the relay opens. Repeat this operation, ending with the relay closed. Remove the jumper and connect it between the supply and either pin 1 or 2 of *IC3*. Remove the jumper and the dc supply.

Once all tests have been made., install all of the ICs. Apply the dc supply and put the 1050-Hz signal from the audio generator on the input. After *IC2* has timed out, the relay should close. Remove the signal input, depress *S1*, and the relay should open and remain open. The circuit is now ready for installation. Note: The tone oscillator if built and frequency-checked for 1050 Hz can be used as an audio generator.

The tone oscillator in Fig. 8 requires only one adjustment to align the frequency adjustment pot for a 1050-Hz output at TP (square wave) or W (triangle wave). Adjust Rt for 50 to 60 mV p-p signal at W, or wait and adjust Rt for consistent tone-alert operation when the decoder is finished and aligned (see Fig. 7 alignment and adjustment information).

They will be fixed-mounted and can even be in the attic if you are not in an aluminum-siding-covered house. The station won't move on you, I promise, so there's no fuss with rotors. Even the "cheapie" monitor radio sounds fine on a good outside antenna instead of its telescoping delight, but try the whip first—it's free with the radio and might amaze you.

As an example, on the Weather-cube from Radio Shack that I had and tried first, indoors and on the whip it sounded OK, but some days it was noisy and some days my tone feature was marginal. That you don't ever want, so just for kicks I lashed it up to my 11-element 2m antenna—unmodified—and the difference was astounding no matter where the antenna was pointed! Not only perfect local copy, but the same on another channel from Chicago 250+ miles away. I merely took a panel-mount screw-in type UHF connector to match the plug on my 2m lead-in with RG-8, soldered a piece of #22 insulated wire to the center pin, wrapped 8 turns (arbitrary) around the base of the collapsed whip (top of radio), and then soldered the remaining end to the ground side of the UHF female. Connect the male from the antenna and voila—signal. Nothing fancy, nothing resonant, perfect copy. Proves if you got it—try it.

In all the configurations I show in Fig. 3, I run the radio off the power source of Fig. 1. In some, that takes a dropping resistor in the + lead to the radio to drop the power source +12 V dc down to the required radio voltage. Most pocket and portable radios of this weather type run off a +9-V dc transistor radio battery. The resistor will be Ohms = 3 volts divided by the radio current in Amps. Wattage of the resistor is 3 volts times the radio current in Amps. Simple Ohm's law. Why, even the appliance operators should not fear this project.

I have shown some various configurations I have tried and listed some possible uses using these lash-ups. The possibilities are as endless as your imagination and time. The examples are specific, but let me generalize a bit.

Configuration 1—This was the original idea: any low-Z speaker output below about 3 Watts, a radio needing about 1/2 Amp or less of +12 V dc or less, and you're in!

Configuration 2—For radios that already have a tone-alert feature, but you still like the standby battery idea.

Configuration 3—Use the idea with a scanner or monitor and decode only net or special calls to be tone type (RTTY?).

Configuration 4—Use a retuned FM tuner, hamfest salvage monitor boards, or 1-to-4-crystal older monitor boards. Buy one crystal—be weather safe! I have seen several of these older monitor boards showing up around the hamfests (Dayton and Indy so far) for $10 or less.

Configuration 5—Same as idea 3 using monitor or scanner.

Configuration 6—Use the time tones of WWV with an inexpensive Timecube™ from Radio Shack. Retune the decoder board to work on the WWV tones you want. Use for contests, 10-minute reminder, etc.

Configuration 7—Use the idea with a converted 11m CB-radio board from one of the flyers (Olson) for use as a local net or ragchew call-up on 10m. The audio outputs are usually missing off these (use Fig. 4), and the transmitter you don't care about for a monitor!

NOTE: Price, Specifications subject to change without notice and obligation.

Configuration 8—Similar to 7, only unconverted CB to monitor CB for REACT channel 9, weather, emergencies.

Configuration 9—I did not show a Configuration 9, but don't over look the possibilities in any of the configurations of added poles on the relays if needed to switch in a tape recorder on those tone call-ups to record a message while you are out. You get a tone call and the caller leaves a message—a nice feature! The recorder can run off the power source just like the radio with an appropriate dropping resistor.

Summary

For the time and money involved, I doubt you could spend a more rewarding weekend of effort. If I were starting from scratch right now and had nothing, I would probably go the Fig. 1 route just for sheer simplicity and lack of cost. The ac power/dc backup is a must. Then go with Fig. 3, Configuration 1. The Radio Shack "CUBE" is a nice little performer for under $20, and it's much less on sale. I have included an Alignment and Adjustment section (see box), and most of these notes are taken right from the original authors' information. I have tried them all, and they work, so I decided to pass them along unchanged. All are of the nature that once done correctly, you can forget them and just enjoy the results. I have not noticed any drift-type problems or anything that would cause a problem when you are counting on the monitor to be working. A very reliable device indeed is what it turned out to be. May your marriage of components and parts be as happy and long lived as mine.■

REVIEW

THE MICROLOG ACT-1 RTTY/CW TERMINAL

At first glance, the Microlog ACT-1 bears a close resemblance to many other keyboards offered to the amateur RTTY and CW enthusiast. There's a keyboard, a couple of switches and an LED on top, and a bank of connectors on the rear panel. Unassuming? Perhaps, but in reality the ACT-1 serves as a firm reminder that appearances can be misleading.

The Features

The ACT-1 is a completely self-contained unit capable of sending and receiving Morse, Baudot, and ASCII codes. It also can send alphanumeric information in SSTV format. By "self-contained," we mean that a demodulator, AFSK generator, video board, and printer interface are all contained inside the keyboard's cabinet. No other devices are necessary, and a few simple connections are sufficient to put the system on the air.

All commands are entered via the 63-key keyboard. In addition to the usual alphanumeric keys, there are special keys like CTRL, KN, AR, SK, and Here Is. Pressing the CTRL or shift key along with one of the other keys results in a command being generated. CTRL M, for example, switches the unit from the RTTY mode to CW. Almost all commands are entered with just two keys. Listing, much less describing, all that the ACT-1 is capable of would take far more space than is available here, so we'll try to hit only the main points.

There is a dual-tone demodulator and a single-channel direct detector. Both demodulators can be inverted with a keyboard command. The dual-tone demodulator decodes both mark and space tones and has a keyboard-selectable high or low tone setting. The high-tone setting provides a standard 170-Hz shift with tones at 2125 and 2295 Hz and is preceded by a sharp bandpass filter. The low-tone setting is also factory set to 170 Hz, but tones are at 800 and 970 Hz. No bandpass filter is provided for this section.

If you find yourself copying a lot of broadcast services, you can reset the low tone pair easily to a more useful pair, like 425-Hz shift at 2125 and 2550.

The single-channel demodulator copies only the mark frequency and is set to decode at 800 Hz, which corresponds nicely to the peak in many receivers' CW filter. It generally is used for copying stations which are using a shift not programmed into either of the settings for the dual-tone demodulator.

Ease of tuning can be a big factor in the amount of satisfaction a demodulator gives. We have grown rather accustomed to the meter-tuning system used in HAL, Macrotronics, and other equipment, so the single LED used for tuning the ACT-1 took us by surprise. It works very well and is at least as efficient as a meter. Best of all, there is a regeneration circuit that lets the user hear what's being decoded. You simply tune the receiver until the code coming from the ACT-1's speaker sounds right.

Tuning is virtually foolproof in either RTTY or CW modes, and the regeneration should be particularly welcome to hams with impaired vision. Those of us who crave silent operation will be equally pleased to know that the monitor is easily turned off by flicking a switch on the front panel. And if you still insist on using an oscilloscope for tuning, rest assured that outputs are provided for this purpose.

Provision for transmitting with either AFSK or FSK is included. Like most manufacturers, Microlog is partial to the AFSK method, and they advocate its use for a variety of reasons which you may or may not find compelling. For rugged individualists who prefer direct FSK keying, ample information on connecting the ACT-1 to a variety of transceivers is included.

Actually, connection to everything is easy and very well documented in the instruction manual. Much attention has been paid to making the ACT-1 compatible with virtually every rig available. You won't have to haywire any special interfaces to get the ACT-1 on the air.

CW keying is available for both negative- and positive-keyed rigs. The maximum negative keydown rating is -150 V at 50 mA. Positive keying is rated at 40 V at 300 mA.

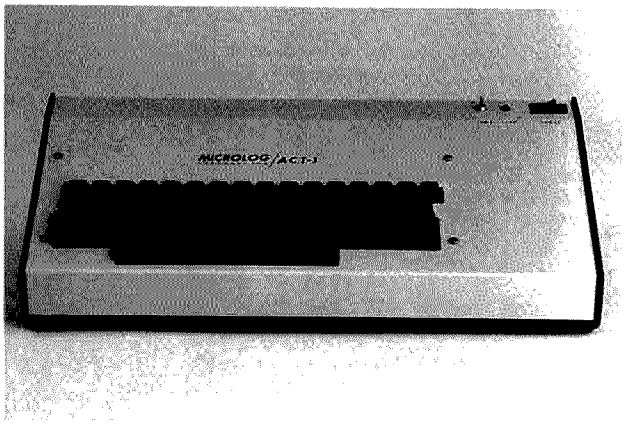
Rear-panel jacks also are provided for a cassette tape recorder, a 40-column serial printer, and an external demodulator. Video output is via a standard photo jack, but since there is plenty of room for a BNC connector, I wonder why one wasn't used.

There is true split-screen operation, allowing the operator to see what he is typing into the buffer while receiving text on the bottom half. The text buffer holds up to 1300 characters, which is certainly respectable. To help customize the system to particular needs, the split line can be set anywhere from none at all to 20 lines down.

When transmitting, the ACT-1 can be set to send as soon as a character has been typed or it can wait until a complete word has been typed. The latter option is convenient because it allows you to catch and correct errors before they go out.

To aid receiving, an ANCW (anti-CW) feature is included, which behaves like the autostart found on other units. When enabled, ANCW inhibits display of non-RTTY signals and is very helpful when tuning across the band reading the mail. The UNOS (unshaft on space) and sync options also behave like similar features on other units. The UNOS shifts the ACT-1 to the LTRS mode on receipt of a Baudot word space code, which prevents the system from getting stuck in the FIGS mode if a burst of interference covers up the command to shift. The sync simply sends a blank code whenever the system is in the transmit mode, but there are no characters to transmit. Both UNOS and sync can be switched off and on from the keyboard.

Baudot speeds of 60, 66, 75, 100, and 132 words per minute, ASCII at 110 and 300 baud, and CW at 5-199 words per minute are available. In the RTTY mode, speeds are selected by typing CTRL X, entering the speed



The Microlog ACT-1. (Photo by KA1LR)

Rear view of the ACT-1. (Photo by KA1LR)

numerically, and then hitting any non-numeric key. This is fine for operators who rarely change speed, but annoying if you are trying to discover what speed a station is using by trying every possibility. Perhaps an option could be added to allow stepping through the speeds by repeatedly pressing a key.

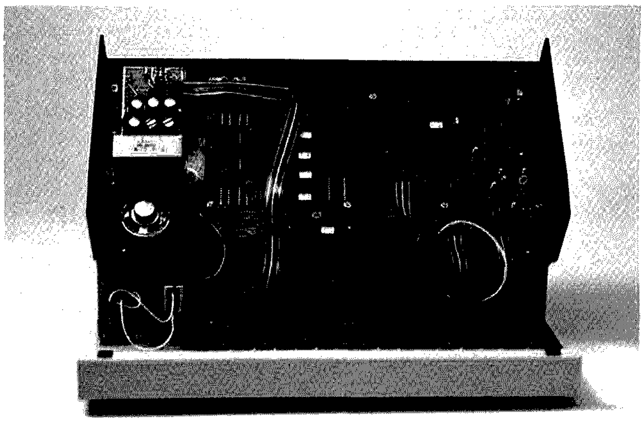
Turning to features which some might term luxuries, there is a real-time clock whose display is always visible at the top of the screen. The time can be transmitted by entering a simple command. The clock must, of course, be reset every time the unit is turned on, but Microlog says that the ACT-1 is designed for continuous-duty operation and never needs to be turned off.

Memories

While the ACT-1's array of memories is not as extensive as that which certain microcomputer interface combination systems offer, there is enough to satisfy most hams' needs. There are two ID memories which hold up to 19 characters each and ten message memories holding up to 40 characters each. The message memories are soft-partitioned, so you can program messages longer than 40 characters if you like. It is possible, for example, to create a single message 400 characters long, but then there won't be room for any other messages.

An eight-character WRU message allows storage of a short code. When the CT-1 receives text that matches the code exactly, it automatically transmits whatever is in the ID memory and then returns to the receive mode. Two selective-print memories allow others to leave a message on your equipment while you are away from the shack. Upon receipt of text that matches the text in the first memory, the printer is activated and hard copy is produced of everything the ACT-1 hears, assuming you have a printer connected. Receipt of text that matches the text in the second memory turns the printer back off. Used together, the WRU and selective-print feature represent a simple but effective means of providing unattended operation.

While not quite as convenient as on-board memory, a reliable interface is provided which allows information to be stored on a cassette tape recorder and



Inside the ACT-1. (Photo by KA1LR)

played back at will. You can record and play back messages entered from the keyboard or copied off the air. Finally, thre are two preprogrammed messages. One sends an RYRY series and the other sends every letter of the alphabet in "quick brown fox..." form.

In Use

Once you have everything figured out (it took us a whole day!), you'll find that the ACT-1 is a powerful tool. You'll find yourself referring to the manual quite often, and it is here that we must voice a small complaint. The instruction manual is one of the best we've seen at describing the steps necessary for interfacing the unit to the rest of the station, but the organization of the how-to-use-it material could stand some improvement. Even the inclusion of a prompt card to be kept on the operating table could make a big difference. With so many commands that don't always use mnemonic devices to aid memory, a prompt card is a must.

Some basic information for beginning RTTY operators also is needed. The manual suggests that beginners get one of the "RTTY-primer handbooks." Since dealers' shelves aren't exactly overflowing with RTTY books, this advice isn't much help to the guy who just got his ACT-1 and wants to put it on the air right away. A short section on RTTY operating procedures really is needed.

We may complain about the manual, but we can't fault the ACT-1's performance. Using it is sheer, unadulterated pleasure! As far as we're concerned, the most important aspect of a self-contained unit is its demodulator, and we've seen some pretty horrible ones. Any reservations we may have had were quickly put aside as we watched the Sanyo monitor display perfect copy from an S-nothing signal buried under SSB splatter, CW, and a couple of other RTTY stations. A remarkable performance. We also enjoyed the variety of shifts that can be copied easily. Broadcast monitoring is great sport, and if you have a general-coverage receiver, you'll want to retune the second filter to 425 Hz immediately.

Operation in the RTTY mode was trouble-free and straightforward. CW operation is as good as anything else we've used—perfect copy from machine-sent code, not-so-perfect copy from the straight key and bug contingent.

Conclusions

Even if you've already decided to use a computer and interface combination for RTTY, the ACT-1 deserves careful consideration. The ACT-1, which has a suggested price of $995, has everything even a serious operator could ask for. Because it is self-contained, it takes up very little room on the operating desk. And even if you are planning to get a computer, a unit like the ACT-1 can free it for more important tasks.

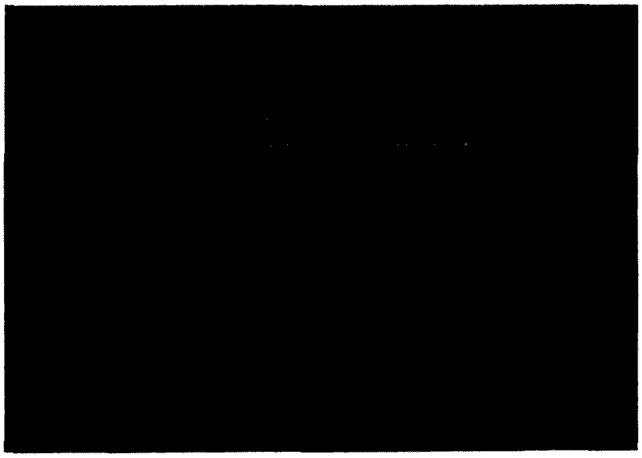
THE MFJ-312 VHF CONVERTER

Most of us have wondered at one time or another just what takes place on our VHF public service bands. The scream of a squad car's siren, a black column of smoke on the horizon, or a threatening weather front in the southwest have given many a ham an urge to plunk down hard cash for a synthesized public service band receiver. If the spirit is willing but the pocketbook is not, take courage. MFJ has a clever new converter that allows a standard two-meter receiver to serve as a receiver for that band.

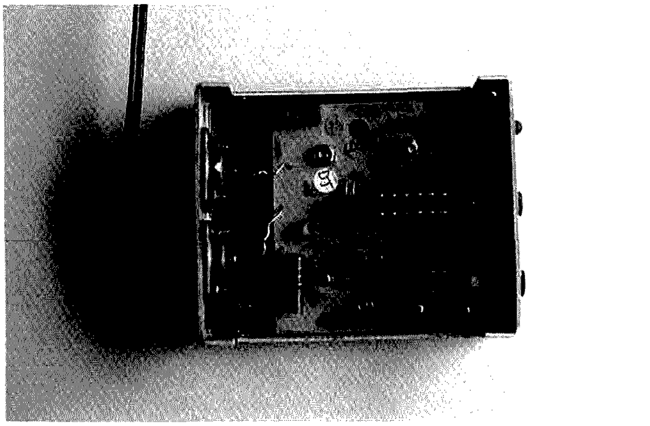
In most installations, the palm-sized MFJ-312 connects to a 12-V-dc power source and a two-meter antenna and transceiver. The converter covers the 160-164-MHz and 154-158-MHz bands, allowing access to police, fire, and NOAA weather transmissions in most areas.

There are only two switches and an LED on the front panel. The left-hand switch selects one of the two bands. The other switches the box in and out of the antenna line and also turns the power on and off.



The MFJ-312. (Photo by KA1LR)

To listen, you merely turn the converter on and tune the two-meter receiver as you would normally. In the 150-154-MHz band, you set the receiver to exactly 10 MHz below the desired frequency. Thus, 154.20 would be heard with the receiver set to 144.20, and 151.335 would be found at 141.335 on your rig's dial. In the 160-164-MHz band, it's a little more challenging—you must set the receiver 16 MHz below desired range. Since the activity in this band is generally limited to a single NOAA weather station, there isn't much of a problem.



The MFJ-312 with top cover removed. (Photo by KA1LR)

In Use

The MFJ-312 performs like a champ. Most listeners won't guess that a converter/receiver combination is being used unless you tell them. The MOSFET mixer and rf amplifier are undoubtedly responsible for the clean, image-free reception. As can be expected, there is a slight increase in noise level when the converter is switched on, but the level never reaches objectionable proportions.

I never tried an antenna cut to 154 MHz, but I suspect that using one might result in an even better performance than I experienced using antennas designed for two meters. For most purposes, a two-meter mobile or base antenna will be more than adequate.

I had a hard time deciding whether to keep the converter in the house or permanently installed in my car. If you contemplate mobile operations, you should be aware that some states and municipalities take a dim view of anyone in a vehicle monitoring the local gendarmes. And even if such activity is perfectly legal in your area, it's healthiest to mount the converter inconspicuously. Don't say I didn't warn you.

Of course, to make the most of this converter, you need a synthesized transceiver. So much the better if you have one with a lot of memories. It's often necessary to bounce between two frequencies to hear both sides of a conversation, so scanning is helpful, too. I used the converter for several months with a KDK transceiver that has two banks of five memories. I used one bank to store public service frequencies and the other for two-meter repeaters. Kenwood, Azden, Yaesu, and others also make transceivers whose scanning capabilities and large number of memories make them ideal for use with the 312.

An interesting feature is the feedthrough of two-meter signals when the converter is switched on. I'm not sure whether this was really intended or not, but MFJ makes the best of it and suggests that you program repeater frequencies amidst the police ones and listen to both even though the converter is switched on. Although signals in the two-meter band are heard with significantly reduced sensitivity in this mode, strong signals come through loud and clear. This is especially useful for those of us who feel obligated to keep an ear open for activity on a certain repeater but don't want to be switching the converter on and off all the time.

This brings up the certainty of accidentally transmitting into the device when it's turned on. MFJ says that the converter is protected against accidental transmissions at power levels up to 25 Watts, but warns that this sort of abuse might be hard on the transmitter's finals. For what it's worth, we pumped 40 Watts into the MFJ-312 for several seconds on many occasions, and neither the transmitter nor the converter complained.

The purists among you are probably wondering what effect if any the converter has on two-meter operations when it's *not* in use. Theoretically, it should have none, since it passes the signal straight through when it is switched out. We noted, however, a slight increase in swr and a corresponding decrease in receiver sensitivity. Emphasis must be placed on the word *slight*. In most areas, the loss either coming or going might not even be noticed. In areas where signals are often less than full-quieting and you need to squeeze every last dB out of your system, you should make provisions for switching the converter out of the circuit when it's not in use.

Conclusions

The MFJ-312 greatly expands one's listening horizons at the very attractive price of $59.95. Using a two-meter rig as the i-f stage makes good sense economically for a ham already equipped with a digital wonder-radio. If you find you enjoy public service listening, the converter will be one of most useful pieces of radio equipment to be had at such a low price. And if you decide that it's really not your cup of tea after all, you'll have the satisfaction of knowing you found out without blowing a week's pay for a scanner!

EMC GROUNDING BRAID

The Electric Motion Company of Winsted, Connecticut, has introduced a product to end hams' grounding woes. Their flexible copper braid is equivalent to #6 AWG(!) and is well-tinned to reduce corrosion. It appears to provide about 2.5 times the conductor area of RG-8/U braid traditionally used for grounding. Best of all, it is supplied in 25- and 50-foot coils, banishing forever the dubious privilege of stripping braid from coax.

In Use

We have had the opportunity to install EMC's product in several shacks and in each case were impressed with the material. The braid should be brought into the shack from a good grounding point, with attention paid to keeping its length as short as possible. The braid can be run either behind the equipment desk, with separate pieces attached to each piece of gear, or to a central grounding point to which all equipment is connected. Both methods seem to work satisfactorily. Care should be taken to ground everything in your system: keyer, clock, amplifiers, low-pass filters, power supplies, the works. We used short pieces of braid for this purpose and were pleased with how easy it is to cut and handle.

We encountered some problems in making connections to the braid due to its formidable size and the poor connnection points provided on many pieces of radio equipment. One high-power amplifier from a prominent manufacturer appears to have no ground point at all! A low-pass filter we use also has no ground connection point, although the instruction sheet supplied with it emphasizes the importance of providing it with a good ground. Some manufacturers provide their gear with the so-called five-way binding post, which is suitable only for relatively small-diameter wire (inadequate for rf grounding). In these and similar cases (assuming the chassis is supposed to be at ground), you should drill a hole in the chassis and fit it out with a hefty connection point and a couple of large washers.

Because of the braid's size, soldering to it can be difficult. It serves as a very long heat sink! Our 300-Watt iron clearly was not equal to the task. You'll either need to make purely mechanical connections using nuts and bolts or round up a more formidable source of heat than the one we tried!

Conclusions

While there undoubtedly has been suitable braid commercially available somewhere before, it is encouraging to see a manufacturer making it available directly to the amateur market.

For those who insist on having a shack that they *know* is set up properly, the EMC braid is a must. There is simply no longer any excuse for rf burns or TVI caused by poor connection to ground! The material should also be useful for bonding automobile body and chassis components together to reduce RFI.

TALKMAN C900 PORTABLE TRANSCEIVER

Standard's Talkman.

Exasperated! It's easy to feel that way when confronted with some of the gadgets produced in the name of progress by the personal communications industry. From glow-in-the-dark CB antennas (you don't have one, do you?) to Bone Fones, there have been some real weirdos. Maybe this helps to explain why I took such delight in the Talkman Model C900, the latest in communications gadgetry from Standard Communications. At last! A gadget that's really worthwhile!

The Talkman is a portable FM transceiver which anyone may operate without a license. Most of the circuitry is contained in a small belt pack measuring just 4" x 2.5" x .75" and weighing a mere 9 ounces. An ultralight headset holds a tiny electric mike, earphone, and whip antenna. Despite its diminutive size, however, the Talkman is not a toy, especially at its suggested $129.95 price tag. The Talkman operates on one of several channels available in the 49.830-49.890 MHz range. Since the rig is sold singly, not in pairs, buyers who hope to do any communicating must be careful to obtain units on the same channel. A letter designation on the back of the belt pack indicates the channel.

Technical Features

Most notably, transmit-receive switching is accomplished using VOX circuitry. This makes operating the Talkman a totally hands-free proposition—a real convenience in many situations. Is this use of VOX a first for a communications device intended for the general public?

A straightforward assemblage of 15 transistors and 4 ICs composes the circuitry of the Talkman. The mode is narrowband FM and, in compliance with Part 15 of the FCC regulations, the transmitter output power is less than 100 mW. On receive, a 0.25-uV signal will break the non-adjustable squelch, and a 0.5-uV signal gives 20 dB of quieting. An ordinary 9-V battery powers the unit. Current drain is 13.5 mA squelched, 70 mA while receiving, and 80 mA in transmit.

Controls on the Talkman are minimal, to say the least, with a pair of three-position slide switches doing it all. One switch turns on the unit and allows selection of low or high earphone volume. The second switch is for VOX sensitivity: low, medium, or high. The higher the setting of this control, the more softly you can speak and still trip the VOX. On the other hand, a lower setting helps to prevent ambient noise from actuating the transmitter.

Does It Work?

Yes, it does. In actual use, the Talkman meets or exceeds the claims made by Standard. With the whip antenna completely deployed, the full 1/4-mile range between units is achieved, although signals are not full quieting. Audio quality is on a par with most amateur hand-helds—not high fidelity, but perfectly OK for spoken communications. The headset is extremely lightweight and a pleasure to use, although the placement of the microphone is extremely important for reliable VOX action. My best results were obtained with the foam windscreen almost touching my lips. One complaint about the headset: The mike boom is a little too short for some adults.

Possibilities

Of course, the proximity of the Talkman's operating frequency to our six-meter ham band led immediately to thoughts of a conversion to 50 MHz. Unfortunately, the Talkmans I tested were not my own, so I was not at liberty to tamper with the innards. A schematic is included with each Talkman, and it appears that altering the operating frequency would not be too difficult. I'm sure it won't be long before we see a few of these little gems on six meters.

In Conclusion

I'd be the last to claim that the Talkman represents any sort of communications breakthrough. Still, for many uses—keeping track of buddies at a hamfest or talking to earthbound helpers from the top of your tower, for example—the Talkman may prove far handier than your handie-talkie. Perhaps we'll begin to see Standard's very convenient headset concept spreading soon to our portable ham rigs. It can't happen too soon for me.

DX

THE UK SCENE

Last year, my family and I enjoyed a holiday in Florida. We tramped most of the usual tourist paths including the Seaquarium, the Kennedy Space Center, the beaches, the fast food stores (still something of a novelty in England), and, of course, Disney World.

Obtaining a reciprocal license was the easiest of all the jobs necessary in planning my USA visit. A photocopy of my current license together with an official letter confirming that it was still active sent to the FCC brought the necessary document within a few weeks.

When I received the reciprocal license, I realized that the only way I could get some HF operating (not being really interested in VHF) was to visit a local ham. I mentioned to Fred Van Aalst WD4RAF, who lives in Fort Lauderdale, that I was planning a visit to Florida and he kindly invited me to meet with him.

While my family and Fred's XYL, Pearl, did some shopping, I activitated G4EJA/W4. Needless to say, it was on a day when the HF bands were in poor shape and I was unable to make any contact with Europe. I called "CQ DX" on 15 and was answered by a WØ. It was a moment before that I realized I was probably as far from him then as I would be at home. There is little point in me describing operating in the US (that would be taking coals to Newcastle, to quote a quaint English proverb).

Jeff Maynard G4EJA operating at the desk of Fred Van Aalst WD4RAF in Ft. Lauderdale, Florida.

The shack of G4EJA showing the RTTY gear with W/K QSL cards in the background.

What might be of interest, however, is the view from this side.

There is no equivalent of the FCC in the United Kingdom. The regulatory body for amateur radio (and for all other aspects of radio) is the Home Office. This is a government body, headed by a Minister (Secretary of State), which looks after, among other things, the police and the maintenance of law and order. The main instrument of control is the Wireless Telegraph Act of 1944 which empowers the Secretary of State to do just about anything. The Home Office is assisted by the Post Office (now known as British Telecom) in such matters as interference suppression and equipment testing.

The first requirement for a license is to pass the Radio Amateur's Examination, known by everyone as the RAE. Sittings for the RAE are held twice each year, usually in May and December, with the results being announced about three months later in each case. The examination paper, which is set by the City and Guilds of London Institute on behalf of the Home Office, is divided into two parts.

Part One deals with licensing conditions and Part Two covers elementary radio theory and operating procedures appropriate to the Radio Amateur Service. For a candidate to be successful, 55% or more of the multiple choice questions must be answered correctly.

An RAE pass slip is all that is required for a "B" license permitting operation at 144 MHz and above (all modes except CW). The "A" or full license for operation on all bands and all modes requires a CW test in addition to passing the theory exam.

The Morse test, which is administered informally by the British Telecom, requires the applicant to send and receive plain text and figure groups at twelve words per minute. Punctuation and procedure signals are not part of the test.

With the license comes a callsign. A particular letter sequence can be asked for and will be given if not already allocated; however, the applicant must wait until that special sequence is ready for issue. The UK callsign system is based on Civil Service logic and is therefore impossible to understand. However, this story would not be complete without a description, so here goes!

The callsign consists of four parts: country identifier, class of license indicator, unique licensee sequence, and optional suffix.

The country identifier is one or two letters at the beginning of the call that indicates that part of the United Kingdom from which the station is currently operating. The prefixes are G—England, GM—Scotland, GI—Northern Ireland, GW—Wales, GD—Isle of Man, GJ—Jersey, and GU—Guernsey.

The country identifier changes when the station moves. Thus if I drive about 25 miles south into the principality of Wales, my callsign becomes GW4EJA/M. This highlights the major difference between UK and USA callsigns; in the UK, the combination of figure and letter sequence (e.g., 4EJA) is unique.

The figure following the country identifier indicates the class of license (except as noted below) as follows: 2,3,4,—A (full) license; 8,6—B (VHF) license.

Some hams from the early days still hold G8 and G6 plus two (e.g., G8AB, G6JM) calls; these are full type-A license holders and are the only way to work these prefixes on HF.

A callsign with a 5 indicates the holder of a reciprocal license.

If I operate from a car, the usual /M is added. The suffix /P is added when operating from a "temporary location" or as a pedestrian. Operating from temporary premises requires the use of the suffix /A (presumed to represent "alternative").

If you understand this all so far, the picture is completed with the GB prefix used for special event stations. Two particular GB callsigns to look out for are GB2RS, the news bulletin station of the Radio Society of Great Britain, and GB2ATG, the RTTY news bulletin station of the British Amateur Radio Teleprinter Group (BARTG).

Having crossed the various bridges to date and obtained a full (A) license, the road is by no means as smooth as it might be. The Wireless Telegraphy Act already mentioned is fraught with problems for the unwary. It is a requirement of the UK amateur license that a licensee must be able to verify that his transmissions are within the authorized frequency band.

It is not permitted in the UK to listen to transmissions other than from authorized broadcast stations and radio amateurs.

The final damping factor is a feature of UK local goverment; it is necessary to obtain "planning permission" for any permanent structure over 10 feet in height. I spent two years battling with my local authority before being allowed (somewhat reluctantly) to erect a tower. Even then the permission was only for a tilt-over and included the rider that it "should be erected for no

OBTAINING A UK RECIPROCAL LICENSE

Citizens of the US intending to visit the United Kingdom may obtain a reciprocal G5 license providing they hold a General, Extra, or Advanced US license (holders of Novice and Technician licenses *cannot* apply even for a UK B-type license).

Applications, on the appropriate form together with a photocopy of the applicant's current license, should be sent to: Amateur Radio Regulatory Dept., The Home Office, Waterloo Bridge House, Waterloo Road, London SE1 8UA.

If a permanent address in the UK can be given, a license for 6 months will be issued; otherwise, a two-month mobile license is given. The current fee is £8. (US $16) for either of these. The callsign will be in the series G5O--.

more than 15 daylight hours per week."

So that's a quick look at the UK amateur radio scene. I hope it will contribute something to more and better QSOs across the pond. Any reader lacking a QSO with England is welcome to a sked (write or telex to 628811) on CW, SSB, or RTTY (or even SSTV with some notice), and if you hear me, I am still chasing counties for QCA and I need Wyoming, Utah, Nevada, Montana, Idaho, and Nebraska for WAS!

Finally, thanks again to Fred WD4RAF for his help in introducing me to stateside operating. Any US hams traveling this way are welcome to call.

Jeff Maynard G4EJA
Cheshire, England

FUN!

CLANDESTINE RADIO

This month's column is devoted to clandestine radio. Recent events have once again proved to us that the right of operating free and open radio stations is something we should never take too lightly. Over the years, both amateurs and non-amateurs have suffered when the privilege of unhindered radio communication has been yanked away by autocratic regimes. This month we pay tribute to those brave individuals and groups who have put the public's right to know above their own personal safety.

ELEMENT 1—CROSSWORD PUZZLE
(Illustration 1)

2) 1941
3) 1954
4) 1975

5) Back in the 1960s, the CIA ran a propaganda station on an obscure Caribbean Island. What was this island's name?

1) Swan Island
2) Hammarlund Island
3) Johnson Island
4) Hallicrafters Island

ELEMENT 3—ALPHABET GAME

Complete the names of the five clandestine broadcast stations listed below by placing letters of the alphabet on every dash. Use each letter only once. The letters J, K, W, X, and Z are not used.

A B C D E F G H I L M N O P Q R S T U V Y

1) VOICE/OF/NA_IB_A
2) VOICE/OF/_A_E_TI_E
3) VOICE/OF/__RE_/_ANAR_/ISL_N_S
4) VOICE/OF/T_E/_AS_UE/_NDER_R_UND
5) VOICE/OF/THE/E_I_REA/RE_OLUTION

ELEMENT 4—HAMAZE
(Illustration 2)

Here's a new type of maze specifically geared to hams. The object is to start at the circle and trace your way to the square by filling in the answers to the clues given below. To help you on the way, we've already given you the first and last clue answers. All words read either vertically downward or from left to right. Each new word is on a *perpendicular* angle to the previous word. Words join on a common letter. Good luck.

1) Organized aggression
2) Stumble speak
3) To hide
4) An organization that may run a clandestine station: ________________ group
5) Discreditable revelation
6) From that place
7) A path
8) Disembarks
9) To view
10) Energy often in short supply to underground stations
11) Secret watcher
12) Aerials
13) 1960s Soviet invasion place
14) Nuts
15) One who is chicken
16) Victor
17) Self-respect
18) Hurry
19) One who plays

THE ANSWERS

Element 1:
See Illustration 1A.

Element 2:
1—1 Peacefully progressing toward what? It's the USSR's answer to Radio Free Europe. (They couldn't call it "Radio Enslaved Europe," could they?)
2—2 WIN was a button.
3—2 Pass the popcorn.
4—2 Patience is a virtue.
5—1 How about "Kenwood Island"?

Element 3:
1—VOICE OF NAMIBIA, 2—VOICE OF PALESTINE, 3—VOICE OF FREE CANARY ISLANDS, 4—VOICE OF THE BASQUE UNDERGROUND, 5—VOICE OF THE ERITREA REVOLUTION.

Element 4:
See Illustration 2A.

SCORING

Element 1:
Twenty-five points for the completed puzzle, or 1/2 point for each question correctly answered.

Element 2:
Five points for each correct answer.

Element 3:
Five points for each correct answer.

Element 4:
Twenty-five points for the completed puzzle, or one point for each word solved.

How'd ya do?

1-20 points—"Is the VOA clandestine?"
21-40 points—Once heard Radio Peking.
41-60 points—Scans the band—but hears nothing.
61-80 points—Single agent.
81-100+ points—Double agent.

NEW PRODUCTS

DRAKE'S NEW TRANSCEIVER AND RECEIVER

The R. L. Drake Company has announced new models of its TR7 communications transceiver and R7 receiver. Features new to the TR7A include standard 9-kHz receive selectivity for AM reception, 500-Hz crystal filter for CW reception, built-in noise blanker, improved lightning protection, and a new phone-patch audio input.

The new R7A receiver features a noise blanker, 500-Hz CW crystal filter, and 9-kHz AM selectivity. These units also interconnect to make a "twins" system, offering complete frequency flexibility and dual simultaneous receive. The TR7A has a suggested price of $1699 and the R7A lists for $1649.

For more information, contact *R. L. Drake Company, 540 Richard Street, Miamisburg OH 45342; (513)-866-2421.*

SEVEN-ELEMENT TRIBANDER

A new tribander, the TH7DX, is now available from Hy-Gain. The TH7DX features a dual-driven element system that maintains a vswr of less than 2:1 on all bands including the entire 10-meter band. The driven elements utilize Hy-Gain's Hy-Q traps capable of handling power levels well in excess of the legal limit. These traps allow element lengths of 0.225 wavelength on 10 meters, 0.203 wavelength on 15 meters, and 0.185 wavelength on 20 meters. The dual-driven elements are fed directly with Hy-Gain's 50-Ohm BN-86 balun.

Tests show average front-to-back ratios of 22 dB on 20 and 15 meters, and 17 dB on 10 meters. The average half-power beamwidth varies from 66 degrees on 20 meters to 63 degrees on 10 meters. With a turning radius of 20 feet and the longest element 31 feet, the antenna is no larger than the Hy-Gain TH6DXX. The TH7DX weighs 75 lbs., has 9.4 square feet of wind surface area, and wind loading of 240 lbs. at 80 mph. The TH7DX, complete with stainless steel hardware, balun, and boom-to-mast clamp, is priced at $499.95.

Hy-Gain also has announced that kit model 392S is available to convert the older TH6DXX to a TH7DX configuration for a suggested net of $199.95.

For more information on these products, contact *Hy-Gain Division, Telex Communications, 9600 Aldrich Ave. So., Minneapolis MN 55420; (612)-884-4051.* Reader Service number 481.

INDUCTIVE MODEM

MFJ Enterprises has introduced their new MFJ-1230 originate/answer modem. The 1230 uses an inductive coupling technique for receiving. This gives reliable data transfer by eliminating errors caused by room noise, vibration, and other acoustic-coupling problems.

This Bell 103-compatible modem operates from 0 to 300 baud, features half- and full-duplex operation, and is crystal-controlled for high stability. An Apple version that plugs into the game port (MFJ-1231) is also available, complete with software.

The MFJ-1230 and MFJ-1231 inductive-coupled modems are available for $129.95 and $139.95 respectively.

For more information, contact *MFJ Enterprises, 921 Louisville Rd., Starkville MS 39759; (601)-323-5869.* Reader Service number 480.

H-8 AND H/Z-89 PROGRAM

MLM Associates now offers a Morse code transceiver program for Heath/Zenith H-8 and H/Z-89 owners interested in digital communications. MLM Morse converts International Morse code from a receiver into an alphanumeric video display and changes characters typed at a terminal into the form needed to activate a transmitter or code-practice oscillator. Features include fast break-in CW operation, automatic switching between transmit and receive, and a split-screen display.

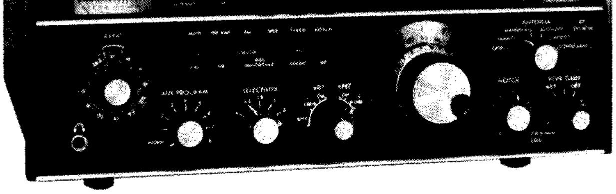
The instruction manual gives details for building a CW-to-computer interface or you can use a RTTY modem. MLM also offers the MFJ-1200 computer interface. The software package sells for $29.95. A complete package including software, interface, and power supply is $99.95.

To order, or for more information, contact *William S. Hall, MLM Associates, 5621 Maple Heights Court, Pittsburgh PA 15232; (412)-683-4742.* Reader Service number 477.

MICROPHONE EQUALIZER

The first in a series of new products from Heil, Ltd., is their EQ 200 Microphone Equalizer for speech applications with SSB and FM transmitters. The EQ 200 allows you to equalize your amateur station in a manner similar to the technique used by broadcast stations and recording studios.

This battery-powered device measures 4" × 4" × 1-1/2" and plugs into the microphone line. The three controls, mike gain, low-frequency adjust, and high-frequency adjust are set with



The Drake TR7A transceiver (top) and R7 receiver.

The MFJ inductive-coupled modem.

the aid of a second receiver or another station. Distortion level is 0.09%. Microphones of any impedance will work, but low-impedance microphones are recommended since they usually offer better RFI protection. The EQ 200 costs $49.95.

For more information, contact *Heil, Ltd., #2 Heil Dr., Marissa IL 62257.* Reader Service number 479.

SURGE PROTECTORS

Alpha Delta Communications' Transi-Trap Surge Protectors are gas surge arresters designed to protect sensitive electronic equipment from damage due to excessive voltages or currents generated by transient phenomena. The elements in the Arc-Plug™ cartridge are constructed of two metal electrodes hermetically sealed in a gas-filled ceramic cylinder. They perform as voltage-dependent switches which can reliably and repeatedly carry large currents for brief periods of time.

Alpha Delta Transi-Trap Protectors are designed for indoor installation at the rear of the equipment. If outdoor use is planned, it will be necessary to coat all surfaces thoroughly with a good sealer. The Model R-T low-level protector is designed for use with solid-state receivers, transceivers, or transmitters that run up to 200 Watts into 50 Ohms. It costs $29.95. The Model HV high-voltage protector is for use with linear amplifiers running up to two kW into 50 Ohms and sells for $32.95.

For more details, contact *Alpha Delta Communications, 116A North Main St., Centerville OH 45459; (513)-435-4772.* Reader Service number 476.

CW-TO-RTTY CONVERTER

Kantronics is introducing a RTTY send/receive device that converts CW from any keyer or keyboard into standard AFSK two-tone RTTY or two-tone CW ID. Micro-RTTY sends and receives at 60, 67, 75, and 100 wpm, plus 110-baud ASCII.

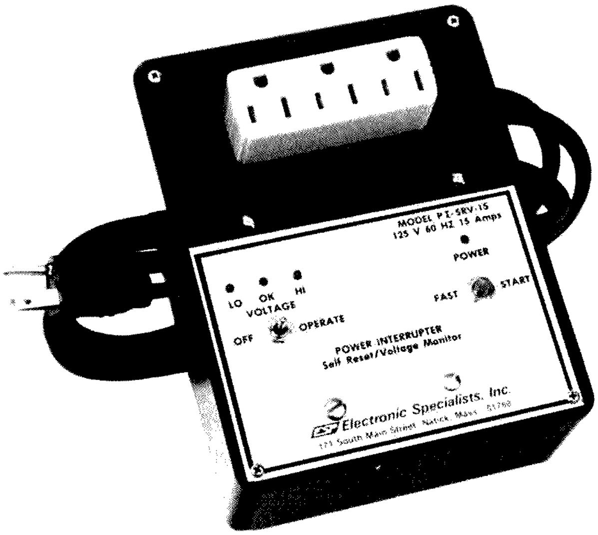
Features include special CW characters for sending a line-return/carriage-feed character and a print attachment. Micro-RTTY receives any shift of RTTY and displays the message on a ten-character, 3/8"-high vacuum-tube fluorescent display. The 2-1/2" × 5" × 5-1/2" package comes with a 9-volt dc power supply and has a suggested price of $299.95.

For more details, contact *Kantronics, 1202 E. 23rd St., Lawrence KS 66044; (913)-842-7745.*

POWER LINE INTERRUPTER

Electronic Specialists now offers an automatic-reset ac power line interrupter. Should the ac line voltage be disrupted or exceed preset safety limits, the power interrupter disconnects ac power from controlled apparatus. A 4-minute timer delay, followed by automatic reset, helps avoid wide voltage fluctuations.

Intended to operate unattended for long periods, the self-reset power interrupter also offers an optional voltage monitor. Connecting to the ac line with a standard 3-prong plug, the power interrupter can accommodate a 15-Ampere resistive load or a 10-Ampere inductive load. The Model PI-SR-15 interrupter costs $185.95; the voltage monitor option costs $20.00 extra.



Electronic Specialists' power line interrupter.

For more information, contact *Electronic Specialists, 171 South Main St., Natick MA 01769; (617)-655-1532.* Reader Service number 482.

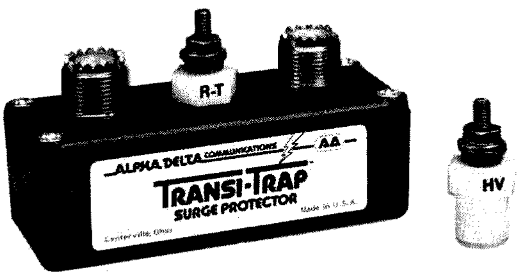
MIKE STAND

Your mobile microphone can now be turned into a base station unit with Valor Enterprises' new Big Ben mike stand. The Model 221 features a black finish and costs $5.90. A chrome version, Model 221C, is also available for $7.90.

To order, or for more information, write to *Valor Enterprises, West Milton OH 45383; (513)-698-4195.* Reader Service number 478.

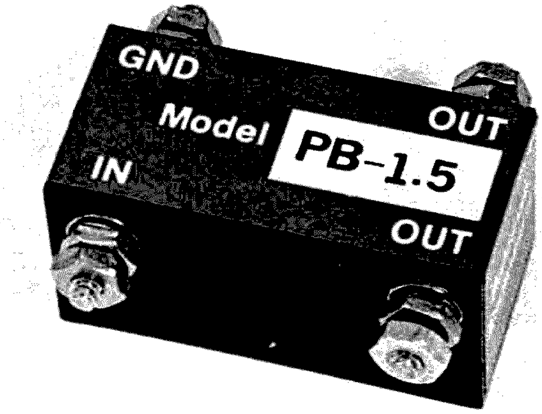
COMPACT ANTENNA BALUNS

Palomar Engineers is introducing a new series of baluns. The Model PB series will match



Transi-Trap gas surge protectors.

The Big Ben mike stand.

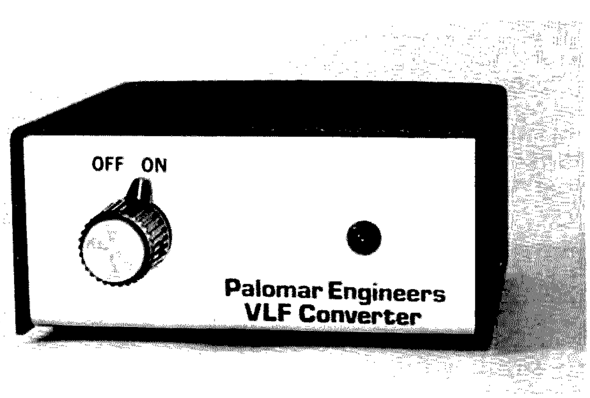


Palomar Engineers' antenna balun.

50-Ohm coaxial cable to 50-, 75-, 100-, 150-, 200-, 250-, 300-, 375-, 450-, 600-, or 800-Ohm balanced antennas. They also can be used as matching transformers for various purposes.

The Model PB series work at power levels to 350 Watts PEP and are 1-1/2" x 3/4" x 3/4" in size. They operate from 1.7 to 30 MHz, are fully encapsulated, and have stainless steel hardware. The PB baluns sell for $14.95.

For further information, contact *Palomar Engineers, 1924-F W. Mission Rd., Escondido CA 92025; (714)-747-3343.*



Palomar Engineers' VLF converter.

VLF CONVERTERS

Palomar Engineers is introducing two new converters for the 10-500-kHz band. They add reception of weather, ship-to-shore CW traffic, RTTY, WWVB, navigation beacons, 1750-meter no-license band, and European low-frequency broadcast stations.

Model VLF-A converts to 3510-4000 kHz for use with ham receivers and transceivers. Model VLF-S converts to 4010-4500 kHz for general-coverage shortwave receivers. With digital readout, the last three digits read frequency.

The new converters feature antenna bypass when turned off, LED power indicator, and low-current, nine-volt dc operation. The VLF-A and VLF-S sell for $79.95.

For further information, contact *Palomar Engineers, 1924-F W. Mission Rd., Escondido CA 92025; (714)-747-3343.*

LETTERS

ATV GOES MONTHLY

Amateur Television Magazine has expanded publication to 12 issues per year beginning with the March, 1982, issue. Now in its 15th year of service to specialized communications operators, *Amateur Television Magazine* covers all modes of amateur television such as FSTV, NBTV, MSTV, and SSTV as well as coverage of FAX, RTTY, microwave, EME, satellites, CATV, and computers.

It was Henry B. Ruh KB9FO, former publisher of *ATV*, who petitioned the FCC to allow SSTV operation in the HF General Class phone segments. This proposal was adopted and is expected to become effective sometime in early 1982, giving a tremendous boost to SSTV activity.

CHARLIE IS BORN

I just read "Messages From Station Charlie," which appeared in the January, 1982, issue of *73*. It was well written and brought back many memories, some pleasant and others I'd rather forget. Perhaps other readers may be interested in the genesis of "Charlie"—station 53C.

In September, 1942, I was assigned to the Office of Strategic Services (OSS), Washington DC. After indoctrination, I was sent to London to confer with [Major General Sir Colin] Gubbins and [Brigadier F. W.] Nichols of the British Special Operations Executive (SOE) with respect to the establishment of an American station to supplement British stations 53A and 53B. The original concept was that we would handle the agent circuits into Norway. The British would arrange for us to get the land required and would furnish Ministry of Works personnel to do the construction, and we would provide the equipment and manpower.

The first thing I did was to drive out London's Great West Road with a receiver, stopping here and there at likely-looking spots to check reception conditions. I saw a road leading up a hill and found myself in a farm worked by Italian prisoners. They doffed their caps and opened gates so I could reach the top of the hill where I found a very large flat area, with low noise level and good reception.

Since throughout England all place-name signs had been removed from roads and railroad stations and buildings, I mapped my route from London to the site with the names of pubs (e.g., Compleat Angler) so that I could identify where I had been when I got back to London!

I am envious of the author's good fortune in meeting those former agents aboard the *Gripsholm*. In my case, I met only one after the war. His name was Robert, and I spent a lovely evening with him and his mother at their home in Paris.

G. L. Graveson K4JI

BINARY STIMULATION

I never write to editors, but had to make an exception in order to respond to your comments concerning CW in your January editorial. The concept of high-speed, computer-based radio communication is definitely an intriguing one, but I must observe that nothing matches Morse code for versatility or CW for simple rf communication.

The average human mind, trained in the use of the code, can interpret the variations in a binary-state stimulus, deriving through that process the information being encoded by the sender. The sender can encode the vast range of human thought that has been or can be reduced to words of human language. I believe the development of the code to be one of mankind's most magnificent achievements.

What do you suggest replacing it with? I know next to nothing about BASIC or other computer languages, but I do know enough to doubt that anyone can communicate with it using an rf oscillator keyed by touching a couple wires to-

gether, as many hams have done at one time or another. As an example of versatility of the *type* of binary system used for transmission, consider the feat of surreptitious communication pulled off by Jeremiah Denton when "interviewed" by his North Vietnamese captors: Using the code, he spelled out the word TORTURE using eyeblinks as the binary system. What computer language would offer such a possibility?

I'm not sure that these comments constitute sufficient reason for the code to be retained as one of the hallmarks of the radio amateur, but radio amateurs are usually people who are intrigued by the notion of action at a distance. The idea of communication over vast distances via an insensible medium is one of the things that "hooks" us on this hobby, and the code makes the medium useful with the least moving parts, which I interpret as being efficient. I sincerely believe that it should not be replaced by a system which requires complex contrivances to access that medium.

R.D. Barnum, D.M.D.
Tahlequah OK

Hi, Ray—It's good to hear from one of the "let's go back to smoke signals" crowd. I don't know what band you operate, Ray, but on most of the CW bands I listen to I do not hear a vast range of human thought being expressed, just the usual garbage of name, location, signal strength, my rig is . . . and 73. Ad infinitum. The code is merely a way to send characters, not thoughts. The characters . . . the same ones we use on our typewriters and that more and more hams are using for code generation (if you've noticed the ads for code-typing systems) . . . can be used to communicate words. The words eventually, in some cases, can be used to communicate thought. No one wants to change that. But it was not my suggestion that amateurs stop using CW; that's a straw man of your construction. I've suggested that we stop making newcomers hate CW by jamming it down their throats. I've tried to point out that anyone who thinks that the code test is keeping out undesirables is blind to what has happened.— Wayne.

TEETHING ON CW

The first thing I turn to when *73 Magazine* arrives each month is "Never Say Die." In spite of your caustic comments about the FCC and *QST*, it makes good reading.

Over the past few months you've bored me somewhat, talking about your business acumen, your contact with the avant-garde of amateurs, your DX operations, plus miscellaneous other achievements. Oh, and your dislike of CW.

Wayne, I cut my teeth on CW in the early thirties when that band was only CW. I've continued in my devotion to CW. Man, it's a language; you have to talk it to retain your ability. I was a Navy Radioman on CW during all of WWII. Early in my ham career I made one 75-meter phone contact. I had mike fright so bad that it wasn't until the early fifties that I got on phone again. Now I spend about 50% of my operating time on SSB.

Being something of an underachiever ham, I sincerely appreciate your fighting spirit, Wayne. As you requested, here are some thoughts about our hobby's social events.

A repeater group has a monthly get-together with wives and children at a local restaurant. For each ham, it's an ego trip. And there are picture-takers and practical jokers. Some are neat; others are slobs. Some act educated; some don't. It's a strange cross-section of humanity, all united by the bond of amateur radio. This group conducts no business. The members simply accept the pleasure of each other's company. The wife and I go as often as we can.

I have been a member of my local club, the Shawnee Amateur Radio Club, for several years. The part of the meeting I always enjoy is the free discussion prior to the business meeting. This is the time I meet and enjoy personal contacts with the local hams. Business meetings are a drag. I'd prefer the nitty-gritty to be handled by the officers at another time.

After the business session comes an "enlightening" talk by an uninformed member—or a slightly-askew slide presentation that I fervently wish I had not stayed for. I stayed for one movie, obtained at considerable effort, which proved to be about 15 or 20 years behind the times. Your suggestion for the "Show and Tell" presentation sounds like a real winner. I hope to see more of this.

Another social event is the hamfest. Except for the horrible crush of Dayton, I always end up with good vibes from hamfests.

About 25 years ago, I joined the Quarter Century Wireless Association and went to an outing at Greenfield Village near Detroit. My immediate reaction was claustrophobia. I had been captured in time many years hence. I wasn't ready for this. I am now a life member of QCWA. My wife and I attend occasional dinner meetings in Indianapolis. Another ego trip, but fun.

Speaking of fun, the real fun of amateur radio is building (or buying) and getting on the air with what you have to communicate with others of like persuasion, talking with other hams, making new friends, and keeping in touch with old friends, on SSB, FM, CW, RTTY, ASCII, SSTV, ATV, OSCAR, or whatever comes down the pike. Long live ham radio!

73 from ex-W9IDP, -W8HXA, -W5JYE, -W0QBF, W9MTR, and -W9LNX.

Paul L. Schmidt W9HD
Bloomfield IN

Paul, we all had to cut our teeth on CW. There is nothing to be proud of for that; we had no other choice. If we can stop trying to use CW as a weapon to ward off people who want to be hams and value it as an art, as the real spirit of amateur radio, perhaps we can be proud of it then. Right now I'm ashamed of CW, for it has failed us utterly in keeping out the trash. I'm pro-CW for fun and keeping up the spirit of amateur radio . . . just let's stop turning prospective hams off it by using it as a weapon against them. You're right about business meetings being a drag . . . keep 'em out and let the club/executive committee waste its hours on that bunk.—Wayne.

CLIMB ON!

After reading all the latest about the League, the plain language debate, and other such discouraging issues, it was most refreshing to read the wonderful article by Scott Nelson W7KUF about their Mount McKinley expedition. It is really uplifting to read about the true functions of amateur radio in action. If not anything else, it will drive me to re-up with *73* to keep informed, join one of the many clubs around here, and volunteer for some of the activities for which the hobby used to be noted. Wayne, I know that throughout the years you have always championed the good cause, and sometimes I wonder where you get all the energy for all the work you do. Be assured that many of ham radio's "silent majority" are behind you 100% and your continued rallying will drag us out of the woodwork, like me. Have a great year!

David R. Waters WA6AWZ
San Jose CA

I feel better already.—Wayne.

HOME-BREWING

Let me congratulate you on the "Home-Brew Contest," which is an excellent idea! The current economic woes of this country have made it all but impossible for amateurs like myself, who have a family to support, to upgrade a station with new equipment. Kits and good used equipment also seem out of the question. The home-brew route provides an alternative to this problem. I would be able to purchase the components as I could afford them and learn a lot more about the state-of-the-art of amateur radio as well.

I might add that your idea underscores what I feel is a growing indifference at the ARRL to the basic needs of the amateur. While I will continue to remain a member of this organization, I am not at all happy with the direction they are going. An amateur who can barely afford to get on the low bands or two meters doesn't need articles on how to track the moon, build a QRP rig in a sardine can, or build expensive accessories. Granted, they do publish an article on receiver construction or the like from time to time. And, granted, there are construction projects in the *Handbook*, but I find the construction details sketchy. This, coupled with the cost of the components, tends to scare me off. This leads me to a suggestion.

As you publish home-brew projects, please consider the possibilitiy of providing detailed

construction plans. By this, I mean a checklist construction guide similar to the method used by the Heath Company. It would certainly give someone like me, who isn't much beyond the code-oscillator stage, the confidence to tackle something like building a receiver.

Right now your business mind is probably rejecting this idea, figuring the cost in money and man hours that would be required to write step-by-step instructions, create illustrations, templates, etc. I agree that this would not be cheap. However, consider the possibility of publishing the construction details a section at a time over several issues of the magazine. Such a continuing series would certainly encourage newsstand sales and subscriptions. The same artwork for the magazine series could also be adapted to your line of amateur publications.

The bottom line, Mr. Green, is that you have an excellent opportunity to make a lasting contribution to the needs of amateur radio. I would encourage you to weigh the possibilities of this idea as you make your publication plans for this contest.

A Shy WD9

First-rate idea.—Wayne.

FUN, CHEAP, AND...

After reading all the "crank" letters in the January, 1982, *73*, I decided to write one of my own. First, I'd like to take issue with people who write in and say that amateur radio is a rich man's hobby. That's a silly statement. Today people pay $500 to $700 for a color TV, $10 to $30 a month for cable charges, $25 for tickets to a bowl game or concert. Amateur radio is cheap entertainment when compared to these other diversions. A state-of-the-art transceiver can be bought for around $500. With a little care, those solid-state beauties will easily last ten years. If an amateur buys one of these rigs, operates twice a week, and brews a pot of coffee each night he operates, at the end of ten years he has spent more on the coffee than the rig. Even then, he could recover a good fraction of his investment by selling the used rig. (For example, check the prices for a used Heath HW-101 compared to the price for a new kit seven or eight years ago. That almost amounts to free entertainment.)

Next, I'd like to console the old-time tinkerers. Tubes are still available. They're cheap. They're functional. If you want to build old-time gear, do it. I've built a few tube CW transmitters and have enjoyed the construction and operation. Please do not yell about others using integrated circuits and transistors. The old-timers were working with state-of-the-art in 1929, and in 1929 tubes were as mysterious as integrated circuits are now (to anyone refusing to learn). This is a hobby, after all. Relax. Read a little, learn a little, and enjoy a lot.

Jim Owens' letter especially bothered me when he said that newcomers in amateur radio must mortgage their homes to buy gear. Jim, take a new guy to a hamfest. Some nice Novice gear (e.g., Heath's HW-16 with vfo, 90 Watts, and full break-in) can be had for less than $100. He doesn't have to sell his home, just carpool for a month and save a few bucks. Jim could even buy such a rig as a spare and loan it to the truly destitute. When the beginner upgrades to a Technician license, he can pick up a rockbound two-meter rig for a similar price. By the time he makes General, he is no longer a newcomer.

Lastly, I'd like to address the people who claim that they are technically oriented and that amateur radio magazines don't publish enough projects. Great! The next time you build a project, take notes, take pictures, write it up, and send it to *73*. Share your ideas with other amateurs, and it will improve the journal you are criticizing.

Amateur radio is fun, cheap, and exciting. If you don't think so, contribute your ideas and improve it. If you can't be bothered to improve or enjoy amateur radio, go to the Y and swim a few laps in the pool. It will be better for your heart and for amateur radio.

Bradley G. Mauger KB5QZ
Greenbelt MD

QSL VIA...

I am QSL Manager for the newly-licensed station VQ9JB on Diego Garcia. The operator, Jay Befort, will be there eight months and I will be handling all of his QSLs. Send your cards to 477 Mose Drive, Biloxi MS 39532.

Shari Runyan WD5BHP
Biloxi MS

LEGITIMATE?

This is in reference to the remarks by Tim Daniel N8RK on cable TV radiation (Letters, January issue of *73*). I am most interested, since I have a foot in each camp.

As a CATV engineer, I resent his shotgun statement, "...many CATV companies are reluctant to upset the apple cart, much less spend any money that would result in a reduction of short-term profits." How many companies? Which ones? How do you know? What do you know about the CATV company's short-term profit?

He says, "The idea of a legitimate amateur repeater shifting its frequency to accommodate CATV does not appeal to me." I remind him that the CATV operation is also "legitimate." The idea, however, is to work together to find a solution, not to hurl tenuously-founded accusations. What he fails to see (or chooses not to recognize) is an old ham problem from way back: The CATV system can be well within FCC specs, i.e., 20 uV/m at 144.25 MHz, and still be copied by a good grade of ham receiver when the antenna is near the cable. Hams have been fighting this forever—talking into a neighbor's hi-fi, although their transmitters are well within FCC specs. The aim is to work with the neighbor to resolve the difficulty.

His final paragraph "...perhaps some high-power transmissions on or about 145.25 MHz will prompt action." makes me cringe. Lynching would also prompt action, but that, too, is unworthy of the ham fraternity. From his letter, I see N8RK as an "I don't like it, so I'll jam it" mentality. As a new ham, I must say he has a vastly different attitude from the many Elmers who have helped me.

Fred Stone KA5MBB
San Angelo TX

Fred, you seem to have read only part of my response. I urged everyone to be "firm but tactful" when trying to solve the problem. A cable system that meets the 20-uV/m rule is not "legitimate" if it violates 76.613b: "The operator of a cable television system that causes interference shall promptly take appropriate measures to eliminate the harmful interference."—N8RK.

SK

After 16 years as the W2 QSL Bureau Manager, I have decided to call it quits. The new bureau's address is North Jersey DX Association, ARRL 2nd District QSL Bureau, PO Box 599, Morris Plains NJ 07950.

Joseph Painter W2BHM is the new manager effective January 1, 1982. The card sorting will be supervised by Ron Levey K2AIO.

The reason for giving up the job? I just celebrated my 81st birthday.

Victor "Digger" Ulrich WA2DIG
Haledon NJ

HAM HELP

I am a Novice who is in search of a working Heathkit RX-1 receiver to complete my station. My income is limited so the price must be very reasonable.

Fred Erickson KA1GGN
105 G. St.
Turners Falls MA 01376

I need help in obtaining a schematic diagram and manual for a Jackson Model CRO-2 oscilloscope, manufactured by Jackson Electrical Instrument Co., Dayton, Ohio. I would be happy to pay for duplication or I will copy and return your original.

Adam J. Patarcity WB3LIQ
47 Bald Cypress La.
Levittown PA 19054

I had a great response to my request for information on the Hallicrafters HT 41, published in the December, 1981, Ham Help. Thank you.

Glenn Churchill KA2IOI
Glens Falls NY

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randallstown MD 21133

Wayne is not overly fond of "April Fool"-type articles. I mention this now because as I get into this month's topic some of you are going to begin to wonder if this is for real.

What would you say to the following situation, which might be observed in my ham shack? I *am sitting* at the desk, *tuning* the receiver, looking for stations. The speaker calls out with a male voice, "CQ CQ CQ DE N3BRB." So far not very exciting sounding, is it? But what if I tell you that the station is transmitting on 3620 kHz and is on RTTY? Now I've got you!

What is it that makes this possible? A rather remarkable new device which turns plain text into speech. Unlike speech synthesizers which use prepackaged vocabularies, this unit's abilities are not constrained by such predetermination.

The unit is the Votrax Type 'N Talk (TNT). Based on the Votrax SC-01 chip, this is probably the most capable speech synthesizer on the market. Let's take a look at this rather remarkable device and then consider how the RTTY-voice is possible.

The Type 'N Talk is a small, two-pound box that may be connected to any computer or related device through an RS-232C link. Text to be spoken is sent to it in plain ASCII, using, for the most part, common spelling. The Type 'N Talk contains a text-to-speech translation system that allows pronunciation "by the rules" for normal English speech.

The synthesizer is connected to the host computer (similarly to a modem or serial printer) through an RS-232C interface. A switch located on the rear panel allows selection of baud rates in the 75- to 9600-baud range. The "clear to send" (CTS) and "ready to send" (RTS) lines are used to inhibit transfer of data to the Type 'N Talk when the internal buffer is full. However, users of systems which do not support these functions of the RS-232C interface may alter the feeding software to allow for sufficient delays to provide for buffer emptying. Speech is generated at a rate roughly equivalent to a 110-baud ASCII transmission.

Data sent to the Type 'N Talk is stored in an input buffer of 750 characters. This is roughly one minute of speech. The need for utilization of the CTS-RTS lines becomes obvious when one realizes that at a data transfer rate of 1200 baud, this buffer will be filled in less than seven seconds, or under one second at 9600 baud.

The contents of the input buffer are then submitted to an internal text-to-speech translator which generates the phoneme equivalents of the text input. These phonemes may be recovered from the Type 'N Talk for storage or further processing as ASCII character strings. Normally, the output of the translator is held in a 128-byte output queue, from which it passes to *the* SC-01 speech chip for processing.

An internal amplifier is provided which is capable of driving an 8-Ohm speaker to an acceptable volume. Of course, the audio may also be recorded, sent over the telephone, or otherwise manipulated.

All of this is remarkable enough, but the Type 'N Talk does not stop there. Software switches are provided, toggled with escape sequences, that allow the Type 'N Talk to provide a variety of functions. For example, data sent to the Type 'N Talk may be processed by the unit, passed down the line to the next RS-232C device in a chain, or both. The ASCII output may be either an echo of the input or a phonetic representation of it. And the Type 'N Talk can be disabled but rendered "transparent," so that it can share an RS-232C line with a printer or *other* serial device.

Several modes of operation also are provided for. In the normal mode, the character group "MARC," for example, is pronounced as my name. Unfortunately, sending "WA3AJR" results in a strange sound, something like "wah thre hajr." In order to allow pronunciation of letter groups, a CAPS mode is available. Here, groups of capital letters, as a callsign, are spelled out, and lowercase text is pronounced. This allows a great deal of flexibility in handling the type of text we frequently see in RTTY (see, there's one of those groups!).

The diagram in Fig. 1 is an attempt to show many *of* these functions and switches in a schematic form. It should be obvious that this is not a simple device, but through its complexity it makes operation straightforward.

But how about that RTTY program, I hear you asking? What I did was take a routine that receives Murray code and modify it to output not only to the screen but also to the Type 'N Talk connected to the computer. I have also provided keyboard commands to switch from the CAPS ON mode to the CAPS OFF, *so* that the CQ is easily identified but the text in a message is pronounced rather than spelled.

Fig. 2 is a flowchart for the program; the full source listing for 6800 computer will be here in RTTY Loop next month.

Turning to the mailbox, we find a note from Don McAllister N7AVJ, in Cedar City UT, who is looking for RTTY programs to run on the new VIC-20 computer. This new entry from Commodore, the folks who brought you the PET, uses the same 6502 CPU that the Apple and KIM use. I suspect, therefore, that some-

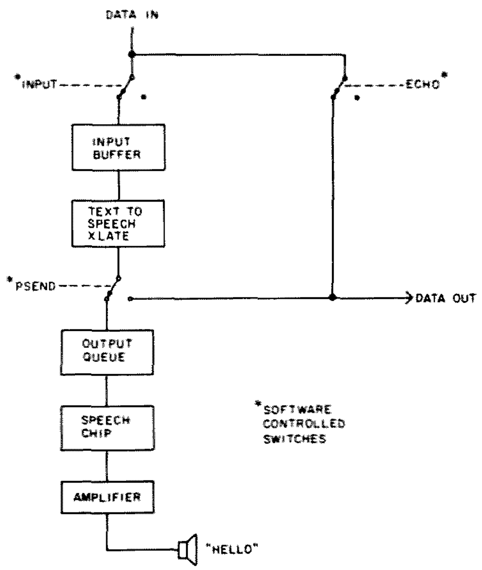

Fig. 1. Block diagram of the Votrax Type 'N Talk.

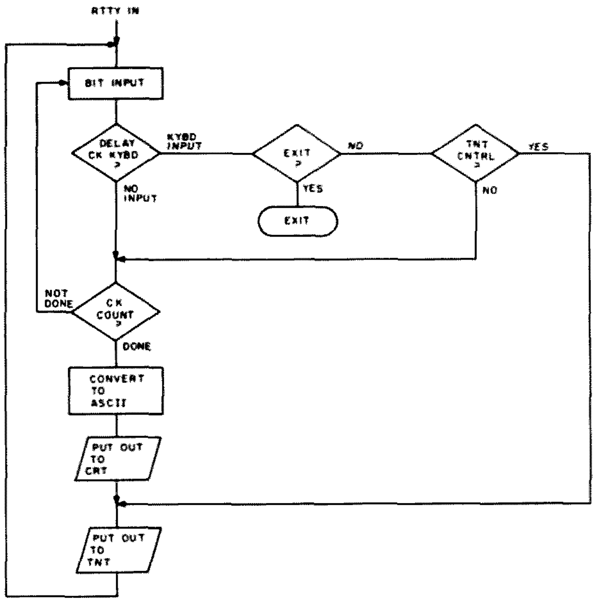

Fig. 2. Flowchart for voice RTTY software.

one handy with 6502 code could adapt one of the many published RTTY programs originally designed for one of those to run on the VIC.

Don also would like to try to put his Sinclair ZX-80 on RTTY. Now, there's a toughy! While this little gem uses a Z-80, my sources tell me that external interfacing may be a bear. I don't have any ready solutions for these problems, Don. If any readers do pass it along, we will share it with all of you.

It's not only the newer systems which keep us on our toes, though. Elston Swanson W3PEE, in Locust Valley NY, has a CP/M-based system—I presume based on an 8080 CPU—that he would like to put on the air on Murray code. Although he has modem drivers for ASCII work, he would like to have a similar Murray routine to allow file transfers and the like.

There have been many RTTY programs published for various 8080- and Z-80-based systems, Elston, and we included a list of the most recent ones in this column a few months back. I suggest you look over some of those programs to see if you could not build a Murray driver into your modem program. That might give you the flexibility you desire without having to reinvent the wheel.

Of course, any readers who are running a CP/M-based Murray system are encouraged to share the information with us all. I never cease to be amazed at the diversity of equipment being used to communicate on this one common mode, RTTY.

We started getting pretty diverse right here this month, what with a voice output for RTTY and all. The program and such will be next month's highlight, along with more surprises, all here in RTTY Loop.

CONTESTS

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

CW & RTTY WORLD CHAMPIONSHIPS

CW Event: 0000 to 2400 GMT, April 3
Phone Event: 0000 to 2400 GMT, April 4

Sponsored jointly by *73 Magazine* and the *RTTY Journal*. Use all bands, 10 through 80 meters, on the specified mode. Cross-mode contacts do not count. The same station may be worked *once* per mode.

Operator classes are: a) single operator, single transmitter, non-computerized; b) single operator, single transmitter, computerized; c) multi-operator, single transmitter, non-computerized; and d) multi-operator, single transmitter, computerized. Single operator stations may work 18 hours maximum per mode, while multi-operator stations may operate the entire 24-hour period. Off times are no less than 30 minutes each and must be noted in logs. To be eligible for the computerized class, your station must be interfaced with a microprocessor-controlled RTTY and/or CW operating system such as the TRS-80, Heath/Zenith, Apple, PET, OSI, Hal, etc. Utilizing a memory keyer for CW does not constitute a computerized station.

Entry categories are: a) CW only, b) RTTY only, and c) CW and RTTY both.

EXCHANGE:

Stations within the 48 contiguous United States and Canada must send RST and state, province, or territory. All others will send RST and a consecutive contact number. If your station is computerized, add the letter "C" to the end of your exchange.

SCORING:

Count 1 QSO point for each valid contact. An additional *bonus* point is earned if the station worked is computerized and sent a "C" at the end of his exchange. Count 1 multiplier point for each of the 48 contiguous United States and each Canadian province/territory and DX country (outside the contiguous US and Canada). The total claimed score is the total QSO points times the total multiplier points.

AWARDS:

Contest awards will be issued in each entry category and operator class in each of the US call districts and Canadian provinces and territories, as well as in each DX country represented. Other awards may be issued at the discretion of the awards committee. A minimum of 5 hours and 50 QSOs must be worked on a mode to be eligible for awards.

ENTRIES:

Entries must include a *separate* log for each event entered, a dupe sheet, a summary sheet, a multiplier check list, and a list of equipment used for each mode of operation. Contestants are asked to send an SASE to the contest address for official forms!

Omission of the required entry forms, operating in excess of legal power, manipulating scores or times to achieve a score advantage, or failure to omit duplicate contacts which would reduce the overall score more than 2% are all grounds for immediate disqualification.

Entries must be postmarked *no later than* May 10th and sent to: CW and RTTY Championships, c/o The *RTTY Journal*, PO Box RY, Cardiff CA 92007.

VS6 ACTIVITY DAYS

Starts: 0001 GMT April 3
Ends: 1700 GMT April 4

As many VS6s as possible will be active during this time period with the sole purpose of giving as many QSOs as possible to other amateurs worldwide. This activity is not meant to be a contest, but rather a weekend set aside to give DXers and awards chasers a chance at working relatively rare Hong Kong. The Hong Kong Amateur Radio Transmitting Society offers two very attractive awards, with the income from the awards helping to finance the VS6 QSL Bureau.

The *Nine Dragons Award:* One QSO with a country in each of the following 9 zones—18, 19, 24, 25, 26, 27, 28, 29, and 30. The zone 24 QSO must be with a VS6 station. Stations within the 9 zones require 2 QSOs in each zone and 2 VS6s. QSOs after January 1, 1979, are accepted. Award fee is $3 US or 25 IRCs. Certified log extracts should be sent; please do not send QSLs.

Firecracker Award: Six QSOs with different VS6s. QSOs must be after January 1, 1964. Award fee is $2 US or 15 IRCs. Send certified log extracts.

CALENDAR

Apr 3-4	**CW & RTTY World Championships**
Apr 10-11	**CARF Phone Commonwealth Contest**
Apr 17-18	**ARCI QRP Spring QSO Party**
Apr 24-25	**YL ISSB QSO Party—Phone**
May 1-2	**County Hunters SSB Contest**
May 15-17	**Michigan QSO Party**
Jun 12-13	**ARRL VHF QSO Party**
Jun 12-13	**Worldwide South America CW Contest**
Jun 26-27	**ARRL Field Day**
Jul 10-11	**IARU Radiosport**
Jul 17-18	**International QRP Contest**
Aug 7-8	**ARRL UHF Contest**
Aug 14-15	**European DX Contest—CW**
Sep 11-12	**ARRL VHF QSO Party**
Sep 11-12	**European DX Contest—Phone**
Oct 16-17	**ARCI QRP CW QSO Party**
Nov 6-7	**ARRL Sweepstakes—CW**
Nov 13-14	**European DX Contest—RTTY**
Nov 20-21	**ARRL Sweepstakes—Phone**
Dec 4-5	**ARRL 160-Meter Contest**
Dec 11-12	**ARRL 10-Meter Contest**

Applications for either award should be addressed to the Hong Kong Amateur Radio Transmitting Society (HARTS), PO Box 541, Hong Kong. As many of their members have QSL managers, you are urged to QSL via the managers and not through the VS6 bureau if at all possible!

CARF PHONE COMMONWEALTH CONTEST

Starts: 1200 GMT April 10
Ends: 1200 GMT April 11

All entrants may use the full 24-hour contest period. All radio amateurs licensed to operate within the Commonwealth or British Mandated Territories are eligible to enter. Use SSB only on the 80- through 10-meter bands. Only one contact may be claimed with a specific station on any one band, and duplicate contacts must be clearly marked as such without claim for points. Contacts may be made with any station using a Commonwealth callsign except those within the entrant's own call area. UK stations may not work each other for points.

EXCHANGE:

A contact consists of an exchange and acknowledgement of an RS report and a three-figure serial number starting at 001 and increasing by one for each successive contact throughout the contest period. Do not send a separate series of serial numbers on each band.

FREQUENCIES:

3600, 3780, 7080, 14180, 21200, 28480.

SCORING:

Each completed contact will score 5 points. In addition, a bonus of 20 points may be claimed for the first, second, and third contacts with each Commonwealth call area on each band.

AWARDS:

The CARF Phone Commonwealth Contest Plaque will be awarded to the top scoring entry in the multi-band class. Certificates will be awarded to top scoring entrants in each class in each Commonwealth call area.

ENTRIES:

Separate logs are required for each band. Each band log should be separately totaled and should include a checklist of call areas worked on that band. Logs should include, for each contact: time in GMT, callsign of station worked, exchange sent and received, points claimed. Separate band totals should be added together and total claimed score entered on a summary sheet.

Entries may be multi-band or single-band. Single-band entries should show contacts for one band only. Only single-operator entries will be accepted. Single-operator entries are manned by one operator only who receives no assistance whatever during the contest period. Multi-band entries are not eligible for single-band awards. Each entry will consist of the separate band logs, call area checklists, a summary sheet, and dupe sheets. Entries should be addressed to: CARF Contests & Awards Committee, PO Box 2172, Station D, Ottawa, Ontario, K1P 5W4 Canada. Under no circumstances should entries for the CARF Phone Commonwealth Contest be sent via the RSGB, nor should entries for RSGB's CW Contest be sent via CARF. The closing date for entries will be June 1st. Official summary sheets are available for an SASE.

QSL OF THE MONTH: W7ON

W7ON believes the best QSL is the simple QSL that instantly communicates a great deal about your station's location. The green saguaro cactus is the symbol of his Arizona QTH; it stands against a desert sand brown wood grain of desert pine. His call letters and address were chosen to be in a brown western font and placed off center to balance the image. The backside is filled out using brown ink to further the desert, dry, barren idea.

If you would like to enter our contest, put your QSL card *in an envelope* and mail it, along with your choice of a book from *73's* Radio Bookshop, to *73 Magazine*, Pine Street, Peterborough NH 03458, Attention: QSL of the Month. Entries which do not use an envelope (the Postal Service does *occasionally* damage cards) and do not specify a book will not be considered.

QRP ARCI SSB QSO PARTY

Starts: 1200 GMT April 17
Ends: 2400 GMT April 18

Participants may operate a maximum of 24 hours during the contest period. Stations may be worked once per band for QSO and multiplier credits.

EXCHANGE:

Members—RS, state/province/country, and QRP number.

Non-members—RST, state/province/country, and power input.

SCORING:

Each member QSO counts 5 points regardless of location. Each non-member US or Canadian contact counts 2 points. Non-members outside W/VE count 4 points. Multipliers are as follows: 8-10 Watts pep output—×2, 6-8 Watts—×4, 4-6 Watts—×6, 2-4 Watts—×8, and less than 2 Watts—×10.

Stations running on more than 10 Watts pep output will count as check logs only. Bonus multiplier is ×2 if 100% natural power (solar, wind, etc.) with no storage or ×1.5 if 100% battery power. Final score is total QSO points times total number of states/provinces/countries per band times the power multiplier times the bonus multiplier (if any).

FREQUENCIES:

1810, 3985, 7285, 14285, 21385, 28885, 50385. All plus or minus to clear interference. VHF/UHF contacts must be direct and not through a repeater.

AWARDS:

Certificates to the highest scoring station in each state, province, or country with two or more entries. Entries are automatically considered for annual Triple Crowns of QRP Award.

LOGS & ENTRIES:

Send large SASE to contest chairman for scoring summary sheet in advance of contest. Separate log sheets are suggested for each band for ease in scoring. Send full log data plus separate work sheet showing details and time(s) off air. No log copies will be returned. All entrants desiring results and scores please include a no.10 envelope with enough US postage for one ounce or an IRC. It is a condition of entry that the decision of the contest chairman of QRP ARCI is final in case

Metroplex

in NJ 201/592-1579

Amateur Communications Association Inc
Box 237, Leonia, New Jersey 07605

NEWSLETTER CONTEST WINNER

This month's winner is published by the Metroplex Amateur Communications Association, a large repeater-oriented group based in northern New Jersey. Editor WA2OVG is a commercial designer, and his influence clearly shows. The Metroplex newsletter is beautifully designed, with excellent layout and classy typography. A newsletter that looks good not only attracts readers, but also catches the eye of potential advertisers. With over a page and a half of advertising in a six-page issue, Metroplex is able to cover a large percentage of the cost of the newsletter without undue drain on the club's treasury.

The moral of the month is: Utilize the talents of your members. If you have a printer, commercial artist, journalist, or photographer in your club, try to convince him to donate some of his time and talent to the cause. A club's greatest asset is its members—don't let their talents go to waste.

of dispute. Logs must be received by May 20th. Logs received after that date or missing information will be used as check logs. Send logs and scoring information to: QRP ARCI Contest Chairman, William W. Dickerson WA2JOC, 352 Crampton Drive, Monroe MI 48161.

ARBOR DAY CELEBRATION

Starts: 2400 GMT April 23
Ends: 0600 GMT April 26

A special events station will be operating from the Nebraska State Arbor Lodge, former home of J. Sterling Morton, founder of Arbor Day, in Nebraska City, Nebraska, during the annual Arbor Day Celebration. This station, in addition to other club member stations, will be operating in the General portion of the phone and CW bands on 80 through 10 meters. All amateurs contacting this station or any other club member station during this time will be eligible to receive an Arbor Day commemorative certificate from the Nebraska City Amateur Radio Club. Please send one dollar and a business-size self-addressed envelope to: John A. Royal WØGRB, PO Box 146, Nehawka NE 68413.

YL ISSB QSO PARTY—PHONE

Starts: 0001 GMT April 24
Ends: 2359 GMT April 25

Two six-hour rest periods are required. Operating categories include: single operator, DX/WK teams, and YL/OM teams. All bands will be used and the same station may be contacted on different bands for contact points but not as country multipliers. Two meters may be used, but contacts must be direct and not through repeaters.

EXCHANGE:

Name, RS, SSBer number, country, state, and partner's call. If no partner, leave blank. If non-member, send "NO NUMBER."

SCORING:

Score five points for each member contacted on any continent. Non-member contacts count one point. Only member station contacts count for multipliers. Multipliers are each state, country, and province, and also each team contacted, but only once for each team. When DX/WK partners contact each other, it counts as a double multiplier. Final score is sum of QSO points times the total multiplier.

ENTRIES:

Logs must show date/time (GMT), RS, SSBer number, partner's call, mode of operation, band, and period of rest time. Summary sheets show number of states, Canadian provinces, countries, YL/OM teams, DX/WK teams, and partner contacts. Send logs, summary sheets, and completed YL ISSB QSO Party applications to Minnie Connolly KAØALX, Star Rt. #1, Crocker MO 65452. Anyone needing blank forms or additional information, send an SASE to the above address.

COUNTY HUNTERS SSB CONTEST

Contest Periods:

0001 to 0800 GMT May 1
1200 GMT May 1 to 0800 GMT May 2
1200 to 2400 GMT May 2

Please note the two 4-hour rest periods.

Mobiles may be worked each time they change counties or bands. Mobiles that are worked again from the same county on a different band count for point credit only. Mobiles that are contacted on a county line count as one contact but 2 multipliers. Fixed stations may be worked by other fixed stations only once during the contest. Repeat QSOs between fixed stations on other bands are not permitted. Fixed stations may be worked by mobiles each time they change counties or bands. Repeat contacts between mobiles are permitted provided they are on a different band or county. Mixed mode contacts are permitted provided that one station is on SSB. Contacts made on net frequencies will not be allowed for scoring in this year's contest.

EXCHANGE:

Signal report, county, and state or country.

FREQUENCIES:

Suggested frequencies are as follows: 3920-3940, 7220-7240, 14275-14295, 21375-21395, 28625-28650.

There will be a "Mobile Window" of 10 kHz on the following frequencies: 3925-3935, 7225-7235, 14280-14290. Mobiles will be in this 10-kHz segment and fixed stations are asked to refrain from calling "CQ CONTEST" in the mobile window. After working mobiles in the window, fixed stations are requested to QSY outside the window to work fixed stations in the contest. This will allow the mobiles running lower power a chance to be heard and worked in the contest. There will be a special effort to work DX on 28.636 by mobiles.

SCORING:

Contact with a fixed US or Canadian station = 1 point. Contact with a DX station (KL7 and KH6 count as DX) = 5 points. Mobile contacts = 15 points. Multiplier = total US counties + Canadian stations. Score = multiplier x total QSO points.

AWARDS:

MARAC plaques to the highest scoring fixed US or Canadian station, DX station, and 2 top-scoring mobile stations. Certificates to the top 10 fixed and mobile stations in the US and Canada and to the highest scoring station in each DX country.

ENTRIES:

Logs must show date and time, station worked, reports exchanged, county, state, band, claimed QSO points (1, 5, or 15), and each new multiplier must be numbered. Logs and summary sheets are free for a #10 SASE or SAE and appropriate IRCs. Write to: John Ferguson WØQWS, 3820 Stonewall Ct., Independence MO 64055.

All entries must be received by June 15th to be eligible for awards. DX entries should use air mail. Winners will be announced at the 1982 Independent County Hunters Convention during July and in the MARAC *Newsletter.*

AWARDS

Bill Gosney KE7C
Micro-80, Inc.
2665 North Busby Road
Oak Harbor WA 98277

NOVICES TO NOVICE

Novices, take heart—here is a mini-expedition for you! Beginning April 17th at 1800 Zulu and continuing until 1800 Zulu on the 18th, the North Texas High-Frequency Association will be operating the Novice bands from Novice, Texas. Look for the mini-expedition about the center of the Novice bands, signing the call KC5YN (Young Novice). Operators will work your calling speed (if you're not too fast), so don't worry about calling. A commemorative QSL will be issued to all stations worked who send a legal-sized SASE.

The NTHFA is the same group that brought you "Phone From Telephone, Texas," the "Alternate Olympics" from Moscow, Texas, and the annual mini-expedition from the decks of the Battleship *Texas*, moored in the Houston ship channel.

We look forward to working you, Novice or not, from Novice, Texas; remember to "Keep Calling Five Young Novices."

SOUTH EAST QUEENSLAND TELETYPE GROUP AWARD

This award is open to all transmitting and listening amateurs. Australian amateurs must score 5 points; overseas amateurs must score 3 points.

To qualify, a station must, where possible, copy the official station of the South East Queensland Teletype Group, VK4TTY, during a news broadcast, and, in the case of a transmitting amateur, participate in the call-back (2 points). A portion of the printout of the news broadcast together with the date, time, frequency, and broadcast number are to accompany the request for the award.

Additionally, a transmitting amateur must work three member stations of the SEQTG on RTTY (1 point each). Log extracts and/or printouts are to be included with the award application, and each member station may be counted only once towards the award.

Listening amateurs should, in lieu of (b), forward log extracts and/or printouts of three contacts involving different member stations of the SEQTG (1 point each).

Applicants for the award should forward the above information together with one dollar Australian or 5 IRCs to cover postage and printing costs, to: the Secretary, SEQTG, PO Box 184, Fortitude Valley, QLD 4006, Australia.

MARCCO AWARDS

The Mobile Amateur Radio Club of Colorado (MARCCO) is an organization of licensed amateur radio operators who engage in HF mobile operations. Meetings are held at noon on the first Friday of every month at Wyatt's Cafeteria, Cherry Creek Shopping Center, Denver. Visiting mobilers are invited to attend the monthly meetings whenever they are in Denver.

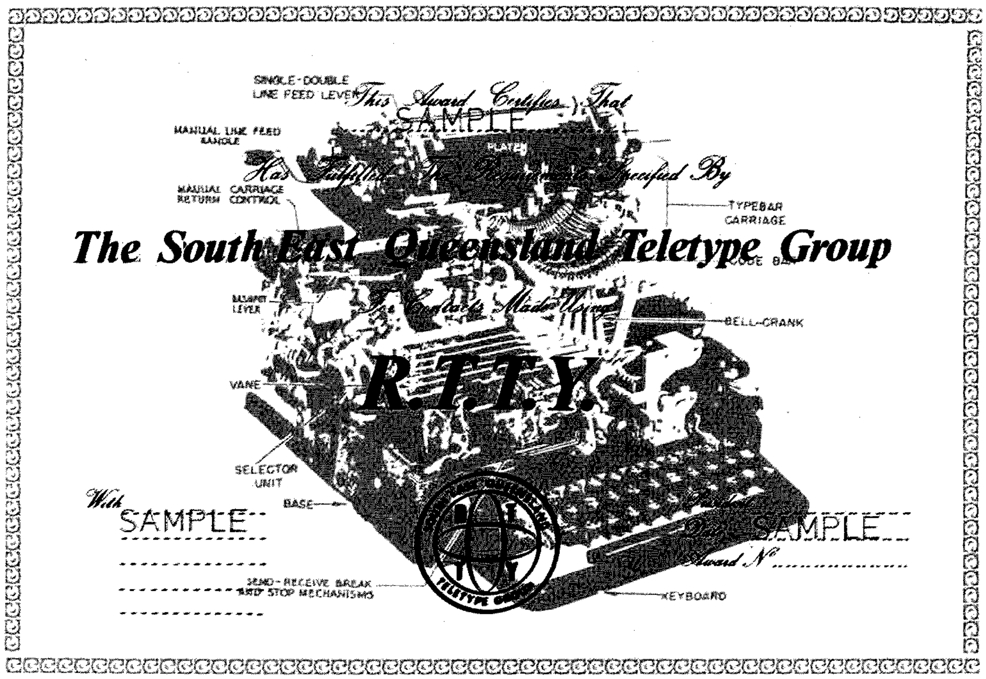
Current MARCCO officers are J.D. Jones WBØBNP, president, Rich High WØHEP, vice president and awards chairman, Paul F. Hultquist WBØSEQ, secretary/treasurer, and John S. Seale, Jr. KDØU, nominating committee chairman.

MARCCO has established several awards effective January 1, 1981. Among them are:

- WACCO Award—Worked mobiles in all Colorado counties.
- Border-to-Border and Coast-to-Coast Awards—Worked mobiles in an unbroken string of counties from Canada to Mexico or from the Atlantic Ocean to the Pacific Ocean. Any string must contain at least three Colorado counties.
- WAMTZ Award—Worked mobiles in all counties in the Mountain Time Zone.

As a gesture of respect and affection for the late Bing Miller WØGV, a charter member of MARCCO, the club will continue the Worked All Bingo award he established for working in all Colorado counties. It will be called the WØGV Memorial Award and will be given for working the same mobile in each of the 63 Colorado counties. Persons who already have worked Bing in one or more Colorado counties, regardless of date, may combine these contacts with those obtained from any other *single* mobile in the remaining counties to qualify for the award.

Log information is sufficient for all MARCCO awards.



For more information concerning awards, contact Rich High WØHEP, MARCCO Awards Chairman, 451 East 58th Avenue 239B, Denver CO 80216; telephone (303)-595-9286.

WORKED ITALIAN ISLANDS AWARD

The WIIA, formerly issued by the DX Old Timers Club (DXOTC), was discontinued when the club ceased its activity. The award has now been resumed by ARI. The new award series will start with number 101.

Scope: The award is issued in order to promote activity from islands belonging to Italy and, especially, from minor islands.

Mode: The award will be issued for 2xCW, 2xSSB, and 2xRTTY. No cross modes or mixed modes are allowed. The award is also available for SWL with no mode restrictions.

Bands: Contacts (or heards) can be made on any band between 3.5 and 29.7 MHz, including those allocated by WARC '79 as soon as they are officially allowed in Italy.

Validity: Contacts (or heards) made on January 1, 1982, or after will count for this award.

Contacts: The award will be issued for contacts (or heards) with not fewer than 10 islands or island groups according to the following list: Tuscan Archipelago IA5, Ponziane Islands IBØ, Neapolitan Archipelago IC8, Eolie (or Lipari) Islands ID9, Island of Ustica IE9, Egadi Islands IF9, Pelagic Islands (Lampedusa, etc.) IG9, Island of Pantelleria IH9, Cheradi Islands IJ7, Tremiti Islands IL7, Minor Islands surrounding the Island of Sardinia IMØ, Sardinia Island ISØ, Sicily Island IT9, for a total of 13. A special endorsement will be mentioned in the award if all 13 islands are contacted (or heard).

In order to be credited for the award, contacts (or heards) shall be made with stations permanently located on an island or island group. Credit also will be given for contacts (or heards) made with stations operating temporarily from such locations. These stations shall identify themselves by using their regular call followed by the prefix assigned to that specific island or island group.

Application: Applications shall include all data regarding contacts (or heards) made. Applicant's name and address should be in block letters and should be forwarded with OSLs or other type of written confirmation of the contacts (or heards) made together with 3 US dollars or 10 IRCs to: ARI Award Manager, G. Nucciotti I8KDB, Via Francanzano 31, 80127 Napoli, Italy.

GCR will not be accepted.

PONY EXPRESS DAY

The Missouri Valley Amateur Radio Club will hold its third annual Pony Express Day on April 10, 1982, from 1000 to 1900 CST. The event commemorates the original running of the Pony Ex-

press from St. Joseph, Missouri, to Sacramento, California. This year the Club also will help the City of St. Joseph celebrate the 100th anniversary of the death of the outlaw Jesse James. This will be accomplished by offering along with the Pony Express certificate a wanted poster of Jesse James.

Anyone making contact with the Club station, WØNH, is eligible to receive both certificates. The operating frequencies will be 10 kHz from the bottom of the General phone bands on 15, 20, 40, and 75 meters. On 10 meters, the frequency will be 28.575. The CW bands will be 28.150 on 10 meters, 21.150 on 15 meters, and 7.125 on 40 meters.

All that is necessary to receive both certificates is to send two first class postage stamps and a QSL card to the Missouri Valley Amateur Radio Club, 401 N. 12th Street, St. Joseph MO 64501.

ALGOA BRANCH AWARD

This award is available free of charge to amateurs throughout the world.

Amateurs outside zone 38 must make at least ten contacts with Algoa Branch members on at least three different bands. Only one contact per branch member per band will count. A sticker for each extra band will be supplied on application, with proof of contact. All contacts must be made subsequent to the formation of the Algoa Branch on April 14, 1979.

A copy of the log or full details of contacts must accompany the application to: The Awards Manager, Algoa Branch Award, PO Box 10050, Port Elizabeth 6015, Republic of South Africa.

Algoa Branch members are as follows; those with the asterisk are members known to be active on the DX bands.

U.S.S. NORTH CAROLINA

The Azalea Coast Amateur Radio Club will be operating from the battleship *U.S.S. North Carolina*, Wilmington NC, on April 17 and 18 from 0830 to 1800 EST. The operating frequencies will be 25 kHz up from the lower edge of the General class phone band.

Please QSL to the Azalea Coast Amateur Radio Club (WD4ORA), PO Box 4044, Wilmington NC 28406, and include an SASE.

ALAMO DXPEDITION

The Border Amateur Radio Society and the Uvalde Radio Club will hold their annual Alamo Village DXpedition on the weekend of April 17-18. W5LFG will be working all bands on

phone and CW. There will be certificates given to amateurs who work them and send an SASE (8" x 10" mailer). We promise 100% QSL to those meeting these requirements.

Alamo Village, a complete reconstructed western town open to tourists and located a few miles outside of Brackettville, is the movie-making capital of Texas. it was the site of the filming of *The Alamo* with John Wayne and *Bandelero* with Dean Martin, as well as many others. The local amateurs will be working out of such sites as the Cantina, Jailhouse, and even a construction of the Alamo itself.

FIRST BRIDGE OVER THE MISSISSIPPI

The Quad Cities Amateur Radio Club, Rock Island, Illinois, will operate special events stations in commemoration of the first bridge across the Mississippi River, which was a significant development in the opening up of the western United States.

W9YCR will be on the air from 1800 hours UCT (noon CST) Saturday, April 17, through 1800 hours UCT, Sunday, April 18, on the 80- through 10-meter bands on the following frequencies: in the middle of the Novice CW portion of each Novice class band, as low in frequency as possible in the General CW portion of each band and 30 kHz up from the lower edge of the General SSB portion of each band.

QSL via Denny Spurgeon N9BKY, 413 23rd Avenue, Moline IL 61265—and please enclose a business-size SASE for a commemorative certificate.

The Quad Cities is a three-county area surrounding Rock Island and Moline, Illinois, and Davenport and Bettendorf, Iowa. It is the farm implement manufacturing capital of the world, the largest metropolitan area in Iowa and Illinois outside of Chicago, and boasts over 1,000 amateur radio operators.

SUN-DAY

The Indian River Amateur Radio Club (IRARC) will participate in a "Sun-Day" exercise in conjunction with the Florida Solar Energy Center at Cape Canaveral, Florida, on Friday, May 7, and Saturday, May 8, 1982.

The IRARC station will be using the Club call, W4NLX/4, and at that time will be operating completely on solar power.

The hours, frequencies, and mode of operation on both days are as follows:

- 1300 to 1400 GMT, 40 meters, 7,250 to 7,275 kHz, SSB.
- 1400 to 2000 GMT, 15 meters, 21,350 to 21,375 kHz, SSB.

A certificate confirming contact or reception will be issued free to each station or short wave listener who sends a QSL and an SASE (foreign—1 IRC) to: Florida Solar Energy Center, Attention: "Sun-Day," 300 State Route 401, Cape Canaveral FL 32920.

ARMED FORCES DAY

This year's observance of Armed Forces Day marks the 33rd anniversary of communications tests between the amateur radio fraternity and military communications systems. The proceedings will include operations on CW, SSB, RTTY, and SSTV.

Special commemorative QSL cards will be awarded to amateurs achieving a verified two-way radio contact with any of the participating military radio stations. Those who receive and accurately copy the Armed Forces Day CW and/or RTTY message from the Secretary of Defense will receive a special commemorative certificate.

Military-to-amateur cross-band operations will be conducted from 1300 UTC May 15 to 0245 UTC May 16. Military stations will transmit on selected military frequencies and listen for stations on a particular amateur frequency specified by the military operator.

Transcriptions of the CW or RTTY receiving tests should be submitted "as received." Submissions should include time, frequency, and the call letters of the military station copied as well as the receiving station's name, callsign, and address on the submitted copy.

Entries must be postmarked no later than May 22, 1982, and be submitted to the appropriate command: NAM, NPG, or NAV entries go to Armed Forces Day Test, Navy-Marine Corps MARS, 4401 Massachusetts Ave. NW, Washington DC 20390. Send WAR submissions to Armed Forces Day Test, Commander 7th Signal Command, ATTN: CCN-PO-OR, Fort Ritchie MD 21719. Send AIR entries to Armed Forces Day Test, 2045th CG/DONJM, Andrews AFB DC 20331.

SMALLEST QTH?

Neffs Area Amateurs (Belmont County) will operate WB8TQG, the smallest ham radio shack in Neffs, Ohio, and perhaps in the world. Work us and let us know if you have a smaller one!

Times: 1600Z May 29 to 2200Z May 30.

Frequencies: Phone—146.46, 28.610, 21.410, 14.340, 7.265, and 3.965; CW—28.120, 21.120, 7.120, and 3.720.

Certificate for QSL card and business SASE to Floyd WB8TQG, PO Box E, Neffs OH 43940.

HAM HELP

We are happy to provide Ham Help listings free, on a space-available basis. We are not happy when we have to take time away from other duties to decipher cryptic notes scrawled illegibly on dog-eared post cards and odd-sized scraps of paper. Please type or print (neatly!), double spaced, your request on an 8½" x 11" sheet of paper and use upper- and lowercase letters where appropriate. Also, please make a "1" look like a "1," not an "l," which could be an "el" or an "eye," and so on. Hard as it may be to believe, we are not familiar with every piece of equipment manufactured on Earth for the last 50 years! Thanks for your cooperation.

I will pay up to $25 each, including postage, for an original or a copy of an instruction manual and schematic for a Gertsch Model FM-3 frequency meter and an RCA type 710 UHF signal generator.

D. S. Toomb N6AFO
841 W. Tenth St.
Claremont CA 91711

I need service manuals for RCA mobile 450-470 MHz transceiver models CLUE BT2 FH and CMUE BT2 FH. Costs for copying or other costs will be reimbursed promptly.

John S. Hoff KA6HRK
15500-A Williams St.
Tustin CA 92680

I would like to obtain an operating manual and schematic diagram for a National NC300 receiver. I will pay any copying costs.

Tom Race
2104 Claremont Terrace
Utica NY 13501

I am in need of a schematic and instruction manual for a Sorensen ac voltage regulator, Model 1000-S.

Mike Pellock NA6J
4955 School House Rd.
Catheys Valley CA 95306

Does anyone have information about a Teletype oscilloscope (Model OS-11/FGC-5) or a Collins military receiver/transmitter (Model RT-441/TRC-68) for the 225-400-MHz band?

Daniel S. Durgin KA1AFJ/8
121 Lake St.
Uhrichsville OH 44683

I need manuals and schematics for Tektronix Model 532 and 545 oscilloscopes, as well as the associated plug-in amplifiers. I will pay for postage and copying.

Larry Beall WA5TUQ
1333 Edgewood
Lufkin TX 75901

I am looking for six-meter conversion information for a General Electric transmitter-receiver unit MT-16u, issue O, option AT2, serial AL 4129.

Noel P. Larson WØCXR
Star Rt. Box 489A
Merrifield MN 56465

Does anyone have an interest in or experience with using microwave oven magnetrons for service in the 2300-MHz amateur band?

Phil Chadwick W3GMK
Route 2
New Hope PA 18938

CORRECTIONS

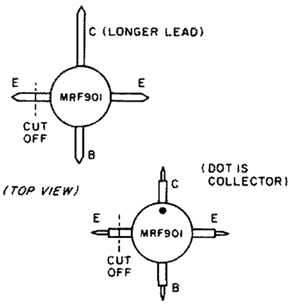

Fig. 1. Pinout diagram for "Amateur Television's Stripper."

"Amateur Television's Stripper" (March, 1982) uses an MRF901 transistor. Several varieties are available, and the accompanying pinout diagram (Fig. 1) may be helpful to readers attempting to duplicate this project.

Tim Daniel N8RK
***73 Magazine* Staff**

I made hesitation controls for Ford, Chrysler, and Toyota automobiles. After I sent you my article ("The Hesitator: A Windshield Wiper Control," January, 1982, *73*, page 40), I made one for a friend who owns a General Motors car and ran into a little difficulty. General Motors has a different wiring philosophy for windshield wipers which makes a simpler wiring job to get into it. Instead of the hesitation control unit momentarily connecting 12 volts to the wiper motor as explained in my article, the GM cars momentarily connect the motor to ground to start a park cycle; see Fig. 2.

The wiring at the motor has a three-pin connector. Determine which pin has 12 V when the ignition switch is on. The pin next to it with two leads is the pin needed for the parking cycle start.

The relay contacts in the hesitation control will have to be wired differently; see Fig. 3.

Henry Edwell N4UH
Cleveland NC

P1-12 33284
560 N. Indiana St.
Porterville CA 93257

I am in need of a schematic and instruction manual for a Drake R-4B. I will copy and return or pay for a photocopy.

William Bohnenberger
18 E 199 St.
Bronx NY 10468

Does anyone have information on an AM-6154/GRT-21 VHF-UHF amplifier that uses an 8930 in a tuned cavity?

Kent Britain WA5VJB
5809 Stageline
Arlington TX 76017

I need someone to repair my VHF Engineering 2-meter synthesizer. I got it quite a while ago new and factory-wired. VHF Engineering is no longer in business. I've tried several places. The Syn II has never worked with my VHF Engineering 2-meter transceiver, which is OK. I may only be making the wrong connections between the two.

I would appreciate hearing from someone who has used the two together.

Tony W. Stalnaker WA4LPJ
2358 Old Al. Rd.
Thomaston GA 30286

I am looking for an instruction manual and schematic for a Navy Model BL-2 transceiver (rec. type CFN-46ABE, trans. type CFN-52ABE) made by Farnsworth Radio and TV Corp. I also need a manual and schematic for a Jackson Model CRO-2 oscilloscope.

Marion Bell KA9BYN
709 West Broadway
Logansport IN 46947

I need any information on the Heathkit SB110A 6m transceiver and/or Heathkit SB500 2m transceiver. Thank you.

Howard Gorden W3CQH
c/o KSI
Suite #2
8403 Dixon Ave.
Silver Spring MD 20910

I am in need of a schematic and manual for an All Star, Jr., all-wave superhet receiver. It is from the early 1930s and uses plug-in coils.

R. F. Bricker K4CSV
PO Box 295
Fort White FL 32038

I am looking for schematics and manuals for a Mercury FC-2 tube tester, Gonset Communicator (FAA version), and a Panoramic Radio Panadaptor model PCA-2T-200.

R. E. Strathkoetter, Sr. WB6SNN
5453 Traymore
Covina CA 91722

I am in need of a schematic for a model BC-1031-C Panoramic adaptor. I would appreciate any information on adapting the BC-1031-C for use with an HW-101.

Gordon Fulp W6FBH
Rt. 3, Box 572A
Placerville CA 95667

I am need of a schematic and tune-up chart for a Hallicrafters SX122.

George Hennessy WB6KJQ
4273½ Fulton Ave.
Sherman Oaks CA 91403

I am trying to get in touch with an old friend. His name is Mike Nicoli WB2XNY/6. I last saw him in El Toro CA where he was attending UC at Irvine. If you have contacted him or know his mailing address, please contact me.

Dennis Duckworth
PO Box 11025
Stanford CA 94305

I am in need of a schematic or any information on a Model 30 printer made by Litton Industries.

Elmer Eddington
1337 West 41st Place
Los Angeles CA 90037

I am in need of a manual or schematic for a Dumont oscilloscope, model 401-A. I will pay for a copy and all associated costs.

Bernard Krull WD2AEU
230 Brinckerhoff Court
Englewood NJ 07631

I would like information that anyone may have on FMing the Heath Seneca.

Larry Campagnano K1PFD
PO Box 171
Guilford CT 06437

I am in need of a three-digit up-down counter circuit that features programmable inputs, reset, a display driver, and digit multiplexer. I am counting pulses from an optical switch used for computer punch-card readers. This is an experimental project so I would like to keep the cost under $5.00.

Larry Starkweather
8231 Camino Del Oro # 3
La Jolla CA 92037

I would like to join a DX association or foundation. Can anyone supply me with addresses and membership information?

Karl M. Leite PS7KM
PO Box 385
59000 Natal
RN, Brasil

OSCAR ORBITS

SYNCART

Quietly, in California and Canada, a group of dedicated amateurs is making steady progress on a plan to place an amateur radio transponder into a geosynchronous orbit above North America. The project is called SYNCART (SYNChronous Amateur Radio Transponder) and it is a collaboration among AMSAT, Project OSCAR, and AMSAT Canada. If all goes well, the transponder could be in orbit as early as 1984.

An object in geosynchronous orbit appears to hang motionless at a point about 23,000 miles above the Earth's equator. Thus, amateurs who use the communications facilities aboard SYNCART could point their antennas toward the proper point in the sky and leave them there. Since SYNCART will not move relative to the surface of the Earth, no complex tracking mechanism will be required. The main disadvantage of a geosynchronous transponder, from the operational point of view, is that it can provide communications to only about one third of the Earth. At least two more such transponders, placed in the correct locations, would be required to provide global coverage. Nevertheless, SYNCART will provide 24-hour-a-day service to most of Region 2.

As with previous amateur space efforts, SYNCART depends upon the scheduled launch of a "professional" satellite for its transportation into orbit. However, unlike other missions in which the amateur payload always separated from the main satellite to assume its own independent orbit, the SYNCART package will remain attached to the main satellite throughout its lifetime. This is a big advantage for the SYNCART planners, since the transponder need not carry its own stabilization and attitude control systems. SYNCART will rely on the main satellite for these crucial necessities.

At present, plans call for SYNCART to carry a 1269-to-435-MHz transponder. A 245-to-435-MHz transponder is also a possibility. There is also an opportunity for linking to the Phase III satellites, since the 435-MHz downlink of SYNCART can be made to fall within the uplink passband of the Phase III birds. Prototype transponders are presently under construction.

It's well to remember that SYNCART is at least two, and more likely three, years away. No flight hardware has yet been built. Still, SYNCART is an exciting prospect and represents another major step forward in amateur space communications.

RS NEWS

Refinements have become available for the robot frequencies given in last month's article about the Soviet Union's RS satellites (*73 Magazine*, March, 1982, page 121). Table 1 contains the latest information.

The Federation of Radiosport of the USSR has set aside Wednesdays (UTC) for experiments on the RS satellites. All amateurs are asked to refrain from transmitting through the satellites on Wednesdays.

RS information is courtesy of the *AMSAT Satellite Report*. For more information on the amateur space program, write to AMSAT, PO Box 27, Washington DC 20044.

BEACON AND ROBOT FREQUENCIES (MHz)

Satellite Name	Beacon Frequency	Robot Uplink	Robot Downlink
RS-3	29.320	–	–
RS-4	29.360	–	–

HAM HELP

I need to know the name of the amateur magazine, with year and month of issue, that had an article describing a means for sorting file cards. There could be one card per article with the appropriate holes punched in the bottom to allow sorting. The author suggested that a commercial version may be available. Any information regarding the article or a source for this kind of file would be appreciated.

Lester R. Lauritzen
Box 117, RFD Route 2
Centerville SD

I am looking for information on the Bendix RTH 27A two-channel FM transceivers used for communication with jet aircraft on the ground. I don't have the command helmets that went with my units. Any information for converting these units to six meters would be welcomed.

Richard Gillespie KC8BQ
107 Ohio Ave.
Charlestown WV 25302

I need a schematic of and service information for a Hy-Gain Model 628G four-channel scanner. I will pay postage and copying costs.

Ray Dunham
477 East 3rd Ave.
Chico CA 95926

I am in need of a schematic and operating manuals for an Eico Model 315 signal generator, TDA-2 telegraph distortion analyzer, and 2M-3/U capacitance analyzer. I will pay copying costs and postage.

H. Hutchison KA0HYH
PSC Box 953
APO MI 34001

I am in need of a Kenwood TR-999 transmitter.

Wayne Hale WA6LCW

solidified; *Banyandah* was to sail to Hawaii early in 1981, outfit herself with complete base-camp equipment, and be ready for the first group of operators by spring. Unfortunately, Harry's time to organize such a massive undertaking diminished as his electronic repair business in Sydney grew, and by late 1980 it became obvious that he would not be able to help on the first leg of this epic adventure.

At that time, the thirty-eight foot *Banyandah* was in the mid-north Pacific, battling heavy seas and gale-force winds on an early-winter crossing from Japan to Hawaii. It appeared that K/P would be an all-American operation, so I turned to my good friend, Karl Jensen KJ7B, in Seattle for help. With his usual efficiency, Karl put the word out through all the DX clubs and bulletins while spreading it across the airwaves. The initial response for the three operators needed was terrific; within a week he had a two-page list of potential candidates. But these glad tidings were short-lived; after the full requirements were explained to each candidate, all but two dropped out. To some, the three-thousand-dollar financial commitment was too steep (although as full-scale DXpeditions go, it was cheap). But to all, the real problem lay in the enormous time required to complete the two operations and make the 2,300-mile voyage. Not many people can afford thirty-five to forty days away from family or employer.

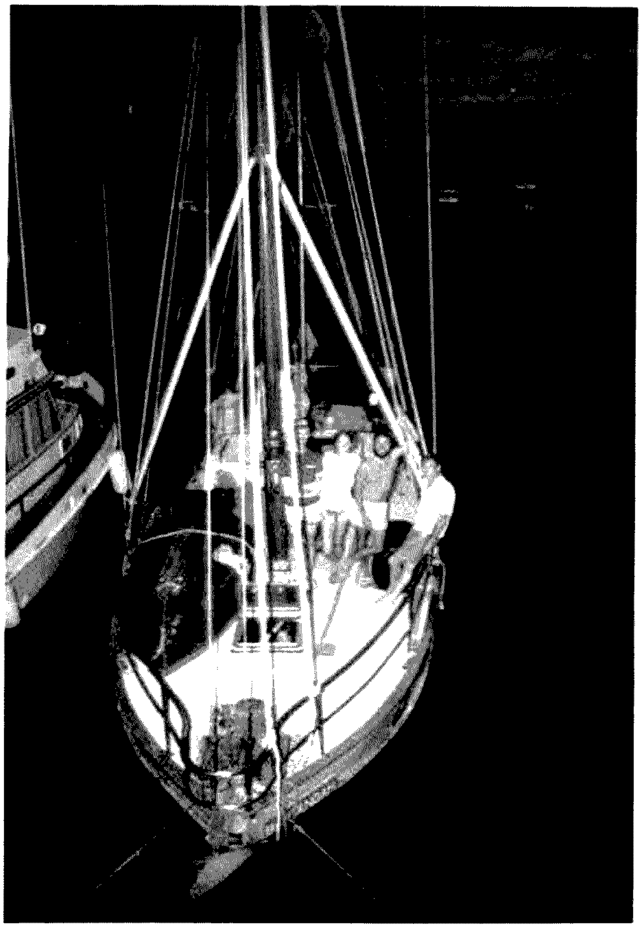
Upon our arrival in Honolulu in early December, we still had only two operators willing to challenge K/P. One, the eventual DX King of Kingman, was a quiet, family man from Minnesota. George Carleton ADØS had a burning desire to try his hand at big-time DXing. In our chats, enthusiasm seemed to ooze from his every rf wave. He was a social worker at one of the state hospitals back in Bremer, Minnesota. A plodder, a converted CB operator, he took to the challenge of DXing like a big gun from W6-land. George and his friends outgrew the local radio club when they met resistance for more DX activities. They formed their own club, the Paul Bunyan Wireless Association, immediately entered every club contest around, and offered night courses for future hams.

George and I were so diametrically opposite in backgrounds that we immediately formed a fast friendship. While I've always been a globe-traveling gypsy, working and living in almost every part of the world, George had never left his native mid-America. He married his childhood sweetheart, stuck with his original employment, and carved a homestead out of thirty acres of rural forested land.

The other operator, the third corner of the triangle, was a fine and proven contest operator from California. Kingman was his dream and an allband operation his goal. More about him later.

As the New Year rolled in, *Banyandah* lay under the highrises at Waikiki and we still had four months of preparations before us. A daily planning session was set up on 15m, with Karl KJ7B acting as the group's central coordinator. Tasks were assigned, with one operator to solicit equipment from manufacturers, the other to solicit financial aid and sponsors. My wife, Judith, and I started the laborious chore of purchasing the numerous supplies and modifying our ship to hold them.

For the base camp, we purchased two large Coleman tents, three folding tables and chairs, a propane cooker, pots and pans, dishes, water containers, sleeping bags and air mattresses, flashlights and internal lighting, all with spares and backups. In other words, our list included everything necessary to exist on a bare pile of shells in the middle of the ocean. On the critical power plant side, we chose the best: two Onan 2.5-kW portable gasoline generators modified especially with automatic oil feeders. They were expensive, but they came with built-in fuel pump, oil pressure pump, and a robust cast-iron engine. A selection of spares also was taken so that any breakdown could be remedied, including a broken crank rod. Hundreds of other items also were loaded aboard for the base camp: large-capacity plastic fuel drums, funnels, fuel transfer pumps, separate power leads for each station, and home-made twenty-seven foot push-up towers with four-foot long stainless steel anchoring stakes.



From left to right: George ADØS, Judith Binder, the author, and Bill W6HTH, aboard the S.Y. Banyandah *before departing for Kingman.*

And let's not forget the food. Case after case came aboard as Judith returned from her forays into Honolulu's markets. Can you imagine the quantity and variety necessary to feed five adults plus our two children for five weeks without a supermarket in sight for a thousand miles?

On the electronics side, matters were not progressing as smoothly. Manufacturers' budgets were getting tighter and tighter. In the past, outright donations

strange forces. For thousands of miles they will remain constant, flowing in one direction at a reliable rate, but upon an approach to land, with the sea bottom suddenly rising, they become unpredictable. To make matters worse, somewhere in this area we would leave one current and enter the world's strangest current, the equatorial countercurrent. This narrow band of water defies all sense by moving directly opposite to the normal trade winds. Its northern limit shifts back and forth across the region at a whim of some unseen force, causing distress among all ship captains who sail this area. Normally, a very wide berth would be given to Kingman, but it was my job to find it safely.

Soon the wind freshened and swung ominously to the southeast. Rain began to fall. It increased until my vision was down to a scant fifty feet. But *Banyandah* heedlessly sailed on, blindly cutting through the water while closing the distance between us and one of this ocean's worst navigational hazards. As the miles ticked off, I held my breath and prayed that my instruments and sights were correct and that our luck would hold. Every few minutes I poked my head above the spray dodger and peered into the rain and gloom, expecting to see that flash of white signalling breakers and destruction.

By 0400 hours, I had had enough and dropped the headsail and mizzen. Quietly, the ship came into the wind, gently rocking in the swell. I woke Judith and crawled into the bunk. "Wake me if the stars show," I said, and immediately fell asleep.

Just before 0600, I was up again. The storm had passed and the first tinges of pink lit the eastern horizon. Quickly Judith and I measured the angle between horizon and our favorite navigational stars, jotting down the exact time of each sight. My voice calling out "Mark!" at each sight must have woken George and Bill; sleep was still in their eyes when they crawled out of the stern cabin. George scanned the blank horizon and said with a grin, "No trees in sight yet." And we all laughed since this was the Minnesotan's usual way of greeting a new day at sea.

George ADØS, making one of the 12,176 KH5/K QSOs.

The star sights didn't take long to work out and showed that we were still thirty miles from that danger which had seemed so near in the rain and the dark. The current had worked its magic and had pushed us away instead of closer. The wind had gone with the passing rain, leaving a calm sea and a bright hot day. Now under power, we continued on a new heading. A scum line was passed—a convergence of currents trapping bits of floating plastic and discarded light bulbs, all alive with small crabs and tiny fish. All morning I tracked the sun with my sextant, and my chart became a mess of intersecting position lines, each a bit closer. By the time the sun reached its azimuth we were very close, and conditions were perfect for a landing.

At 1300 hours I climbed our forty-five-foot mast and scanned the horizon. The sea was flat and calm, the horizon sharp but empty. At 1400, with (supposedly) only six miles to go, I climbed again. There! Just near the edge of the world a vague splash of white showed for a moment and I couldn't believe my luck. The breakers of Kingman Reef were in sight! At deck level, the rest of the crew jumped up and ran to the rail, but nothing could be seen. For the next hour they strained for their first glimpse. Finally, with only two miles to go, George let out a whoop of delight. The rest happened fast. One moment a flat sea, the next a long line of small breakers off our beam and the sea changed from deep blue to aquamarine. Coral heads seemed to rush up to meet us. As we crossed the sunken reef, they were plainly visible even though the depth meter recorded seventy-five feet.

Portable KH5/K first appeared as a heap of brilliant yellow-white sand, sterile and completely devoid of vegetation. The ridge of fine coral rubble and upturned coral boulders was the result of thousands, maybe millions, of years of the sea crashing against the outer barrier reef and washing the broken bits of coral and dead shells into a pile. Excitement ran high as we toured the area in the lee of the cay, taking soundings for anchoring.

It was then that we met the first evidence of Kingman's wildness. Although the depth recorder showed a steady bottom, it was over two hundred feet down! And it was all the same, right up to the perpendicular cliff of reef. At a quarter mile off, I said a silent prayer and lowered the anchor down into the blue, paying out every inch of warp, shaking my head as it slithered over the bow rollers and disappeared from sight.

The cay seemed to grow smaller instead of bigger as we approached in our ten-foot aluminum dingy. Soon it could be seen that its side was steep and not the long gentle slope we had first seen. Kingman was not smooth sand but an im-

stores) appears to provide a good, inexpensive solution.

Ground

A quarter-wave antenna requires a low-resistance ground to be an efficient radiator. The station equipment must be properly grounded to keep rf off the equipment chassis and to prevent rf feedback. The grounding arrangement that met these requirements is shown in Fig. 2. The heavy straps shown are all 3/8" braid.

It is common practice to increase radiating efficiency (reduce ground losses) of electrically short antennas by laying quarter-wave conductors out in all directions from the base of the antenna either on or below the ground—the more radials the better. Since in this installation the base of the endfed inverted-L is terminated at the house and because of the narrow width of the lot, even a small number of radials cannot be accommodated. I settled for one 135-foot radial connected to the common ground point inside the window, dropping directly from the window to the ground below and running approximately under and approximately parallel to the horizontal portion of the antenna. The single radial is buried a few inches under the ground to get it out of harm's way.

It did not take long to determine that this antenna and ground combination was a good radiator. However, it left much to be desired as a receiving antenna. Consistently, I was being copied by stations that I could not pull out of the noise. Consistently, the other stations were copying stations that I could not copy. My station was "receiving limited."

Receiving Antenna and Preamplifier

In searching for a better

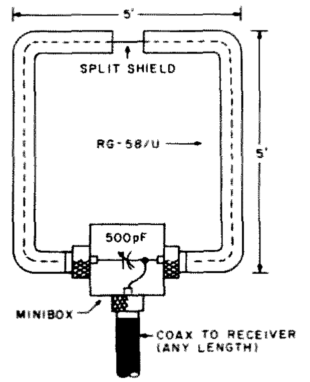


Fig. 3. Loop receiving antenna.

receiving antenna, I came across the 5-foot, single-turn, shielded loop in *The ARRL Antenna Handbook* (see Fig. 3). Much to my surprise and delight, this little loop mounted two feet above the ground and working into a preamplifier proved to be a simple, convenient antenna with superior performance. The loop was made of RG-58/U coax mounted on a 6½-foot wooden dowel mast with light wood cross pieces. The mast was mounted on a TV antenna rotor which was in turn mounted on a 2-foot-square plywood base. RG-58/U was also used for the feedline. With the recent reopening of 160, it would be better to construct the loop and feed using lower-capacitance RG-59/U foam cable. This would provide increased performance across the band.

The signal level produced by the loop antenna is quite low but easily can be boosted to an acceptable level with a simple transistor preamplifier. Because the preamp I used was home-built and because there are some associated system ramifications, a description of the circuit is included here (Fig. 4).

This simple preamp was not designed, but rather built from the simplest FET circuit I could find out of

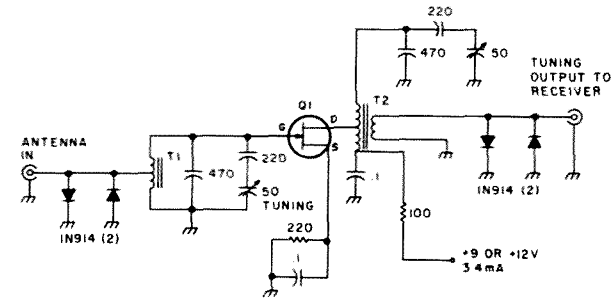

Fig. 4. 160-meter preamplifier. Q1—FET, Radio Shack 276-2036; T1—Amidon T50-2 toroid core, approximately 50 turns (core full), tapped at 6 turns; T2 is the same as T1 except that it is tapped at the center and has a 6-turn link over the ground end.

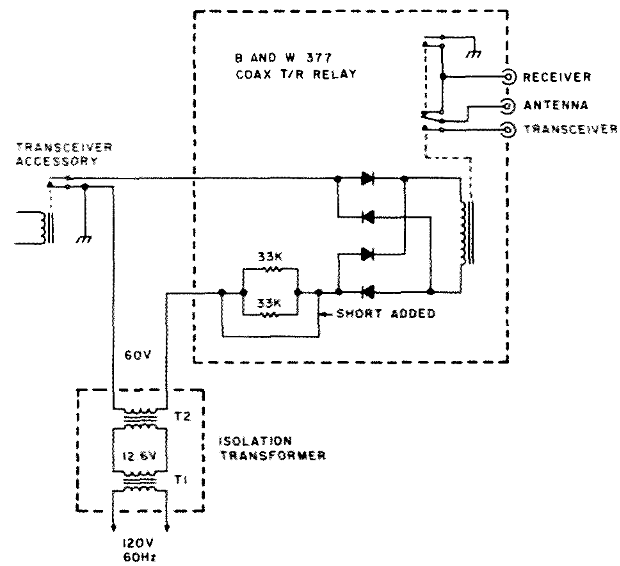

Fig. 5. T-R relay details. T1—Radio Shack 273-1505, 120:12.6 V, 1.2 A; T2—Radio Shack 273-1386, 120:25.2 V, 0.3 A.

available parts. The input and output tuned circuits were arranged to cover 1800 to 1850 kHz. It could undoubtedly be improved, possibly by broad-banding, to eliminate the need for tuning. It provides a gain approaching 20 dB, but in my "brassboard" model is uncomfortably close to oscillation. It performed well enough on the first try that no effort was put into improving it. It would have to be modified to cover more than the 1800-to-1850-kHz portion of the band.

Since this article was first written, the 160-meter band has been opened to 1900 kHz and the loop performance has been improved by replacing the preamp in Fig. 4 with an untuned broadband preamp at the base of and connected directly to the loop.

Note the protective diodes in both the input and output of the preamp. The input is wide open on transmit and there is a danger of transmitting into the output, hence the diode protection on both ends. With 100 Watts into the inverted-L and with the loop antenna about 10 feet from the downlead, a peak audio-frequency signal of 6 volts is developed across the

more heat, which causes more current. Eventually, the transistor can self-destruct. VMOS FETS have just the opposite effect—more heat tends to decrease current flow.

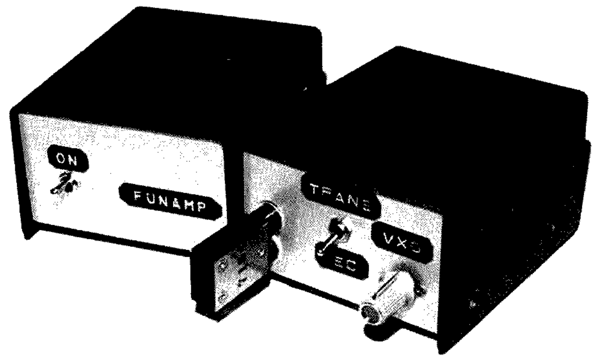
Mismatch burnout occurs in regular transistors when an impedance mismatch occurs between the load (antenna) and the output network. This is seen when a high swr exists—such as with an open line or non-resonant antenna. This condition can destroy most transistors quickly, but the VMOS FET comes through with flying colors.

Additional benefits of the VMOS FET are the ease of parallel use and ease of matching input and output. In order to reach the 20-Watt output level with Radio Shack parts, it was necessary to parallel three VN67AF VMOS FETs. No current hogging exists with VMOS, so no "ballasting" resistors were needed.

One problem of the VN67AF VMOS is the built-in static protection zener diode. This diode limits the maximum gate-to-source voltage which in turn limits the output power. Unfortunately, Radio Shack sells only the VN67AF. VMOS devices are manufactured without the zener diode, but in order to meet the objective of Radio Shack part usage, they were not used.

Fig. 1 shows the simple schematic of the Fun-Amp. I decided to use as simple a design as possible and thus eliminated an input network and an intricate output transformer. A good design goal for home-built equipment is "make it as simple as possible." The amplifier, however, does not suffer in performance due to the simplicity.

The input from the Fun-Mitter is applied to a "pi-type" attenuator (R1, R2, R3). This reduces the input power to the VMOS FETs to the needed level. The Fun-Amp can be driven with only 2 Watts, if desired, to reach the 20-Watt output level. This will be described in detail later. Three VN67AF VMOS FETs are used in parallel to generate the 20 Watts of rf power. Each FET supplies about 1/3 of the total power.



Because of the VMOS's built-in zener diode, CR1 has been added to the circuit. It clips the input sine-wave signal so that it does not go negative. If CR1 was not in the circuit, the FET would quickly be destroyed.

There is no forward bias used on the FETs and thus the amplifier operates in Class C. This is significant for two reasons. One, the amplifier can be used only for CW operation. SSB operation will result in severe distortion. Secondly, Class C operation results in high efficiency (power in/power out), which is a definite plus.

The output network consists of L2, L3, and C3. This network is commonly referred to as a T-network and its function is to match the output impedance of Q1-Q3(16Ω) to the 50Ω antenna load. It also offers some harmonic attenuation. L2 and L3 are constructed from Radio Shack 10-μH rf chokes—a technique familiar to builders of the earlier gear.

The amplifier is operated from +24 V, same as the Fun-Mitter. Current needed for the amplifier is around one Amp. The power supply described in the Fun-Mitter article should work fine, provided the regulator is mounted on a good heat sink, such as part number 276-1361. Total demand from the supply if both the Fun-Mitter and Fun-Amp

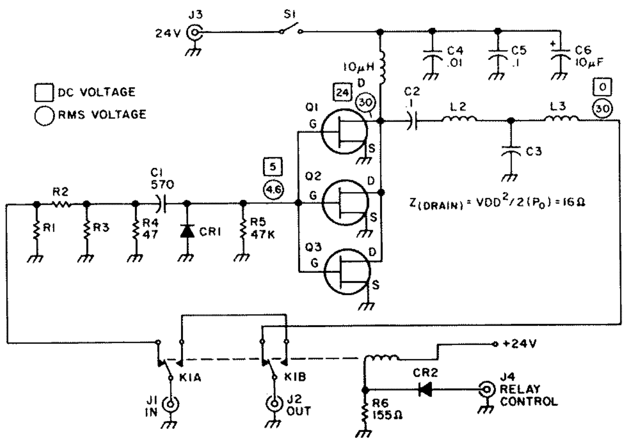

Fig. 1. Schematic.

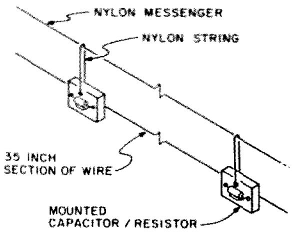

Fig. 3. Nylon messenger and 1 section of antenna.

tenna was suspended. Initially, I hung the messenger 3½ feet above the ground.

Next, I made a jig on a piece of wood which had two nails separated exactly 35 inches. Then I bent 48 pieces of wire around the nails, leaving a 2-inch tail at each end. The tails are used to tie in the resistor/condenser combination. When you've finished cutting and bending the 48 pieces of wire, put them aside in a neat arrangement so they won't snarl.

I used 46 one-Watt resistors, with a value of 47k, and 46 Mallory SXM 339 capacitors, 390 pF, at 160 volts dc. Prior to installing these capacitors, I found that 2 were defective, and 1 was not within tolerance. The testing of the capacitors prior to installation can save you a lot of problems and work later on.

The next job was to make 48 insulators and the feedpoint insulator. I used some 1/8-inch Lucite that I had in the junk box. Figs. 1 and 2 give the details. The next step involved mounting and soldering a capacitor and resistor to each section of wire. Remember, you have 48 sections of wire and only 46 capacitor/resistor combinations. Start at the feedpoint insulator and connect the first section of wire (the end without the insulator) to the feedpoint insulator solder lug and solder it.

The other end of the wire will have the capacitor/resistor mounted on an insulator. Refer to Fig. 1 and note the hole at the top middle of the insulator. I used a 7-inch piece of nylon string and suspended the insulator about 3 inches below the messenger. I continued this process until all the sections were installed and soldered. Using this method of suspending the wire sections allows the antenna to ride free, with no mechanical strain on it whatsoever. So far the antenna has withstood 45-mph winds, rain, and hot sun without any problems. Fig. 3 shows a section of the completed antenna.

The mechanical work is now completed, and we're ready to begin the preliminary antenna tests. I used the authors' design criteria[1] for a 40-meter antenna with a low frequency cutoff of 7050 kHz. I connected a 3-turn loop at the feedpoint insulator and, using a grid-dip meter, resonance occurred at 7002 kHz. Next, the 300-Ohm TV feedline was connected to the feedpoint. About 80 feet of line was needed to reach the shack. I prefer the use of an antenna tuner rather than a 4:1 step-up transformer, because a tuner permits you to tune out any residual reactance in the overall antenna system. Next, I tuned up the transceiver on 7200 kHz and adjusted the antenna tuner for minimum swr between the exciter and the input of the antenna tuner. Using a Bird wattmeter, I set the output of the exciter to 1 Watt. Any swr meter will serve the same purpose; the main consideration here is that only a minimum of power is required to excite the antenna. The rf indicator which I used to check each section of the antenna consisted of a 50 μA meter, using a couple of 1N34s as rectifiers. A 6-inch piece of wire was used as the rf probe. Next, I walked the entire length of the antenna, holding the rf probe at a uniform distance from the antenna, and checked each section. At the ends of each section, I recorded 12 μA, and near the middle of each section, the rf probe indicated 29 μA. These same approximate readings occurred at each section, right down to each end. In other words, I had a uniform radiating surface over the entire length of the antenna. Remember, this antenna is only 3½ feet above ground. It didn't take me long to get back into the shack and fire up on 40 meters.

The first thing that I noticed was that the receiver was very quiet. Signals were right up there in strength. I made three contacts (about 200 miles) and my reports were Q5 and S9 plus. This was with 100 W dc input. I left the antenna at 3½ feet for about a month and did a lot of listening and QSOing. The results have been more than gratifying.

My next task was to raise the antenna to 50 feet. This was a snap with the nylon messenger. All I had to do was coil the antenna up, take it to the mast, stretch it out, attach the feedpoint insulator to the halyard, and pull it up. Next the ends of each messenger were snaked through and among the trees and secured wherever convenient. I find it difficult to describe the physical configuration of the antenna, but the feedpoint is up about 50 feet and the rest of the antenna is hidden among the trees. I have 86 trees on the property and an XYL who loves trees; 'nuff said.

All in all, I'm very happy with the results of this antenna and I'm thankful to W4FD and W4ATE for providing me with a very interesting and rewarding project. ■

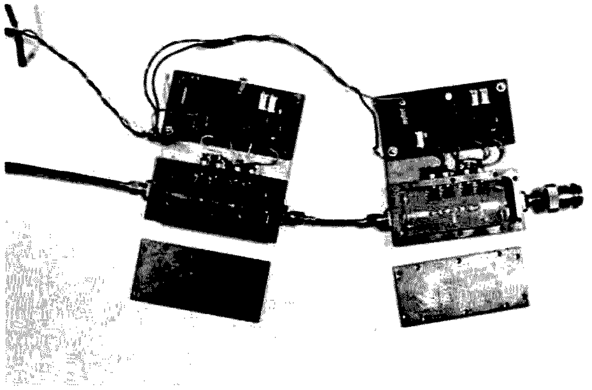
One stage of the low noise amplifier (LNA) described in "Job's Own LNA," 73 Magazine, February, 1982.



Complete LNA with bias power supplies.

average technician can easily duplicate our system. You don't have to be a microwave engineer to make it work.

To develop the complete satellite TV receiving system, we used 15 square feet of printed circuit board, 18 pounds of ammonium persulfate etchant for the board, 5 pieces of 10" × 20" photo reversing film making negatives for boards, 48 pounds of coffee, and 32 cartons of cigarettes. We designed, built, and debugged approximately 40 individual printed circuit boards trying various circuits.

We will describe as we go some of the things we tried that either didn't work or didn't meet our expectations. During our development, we were extremely fortunate to have a professional video technician, Alex Guarino WA4OCG, to critique our received signal video and offer suggestions on improving it. Alex now favorably compares our received video with the commercial cable TV installations with which he is familiar.

We had never seen a satellite TV installation before we got our homebrew system working and, during the development of our system, we did not have access to any test equipment that functions on the satellite TV frequencies. The only test equipment used to debug the system was an old Heathkit Tunnel Dipper (grid-dip meter), a sweep generator, a marker generator, and a 5-MHz Heathkit oscilloscope. So, if we can make a receiver work with our very limited test equipment, we feel that any average technician, using our proven PC board designs, can easily duplicate our system.

The "IV" in the 'Lite Receiver IV* signifies that it is the fourth generation receiver that we have built. The last two were built from the exact PC boards which are in these articles, and they worked the first time power was applied!

*'Lite Receiver IV is a trademark of Martcomm, Inc.

70-MHz Bandpass Filter and I-f Amplifier

Just like your ham band receiver, the signal from the mixer contains many signals and noise. Therefore, the first step after the mixer is to clean up the signal and eliminate all frequencies we don't need. The output of the mixer is a low-level signal of approximately −50 dBm. Refer to Fig. 2, the filter/amplifier schematic. This low-level signal is applied to IC A-1, a Motorola MWA-120 broadband amplifier with 14 dB of gain.

70-MHz Bandpass Filter/I-f Amplifier
Parts List

- 1 2-1/4" × 4" × 2-1/2" minibox, Bud CU-3003A
- 1 PC board, double-sided (Martcomm, Inc., Box 74, Mobile AL 36601)
- 3 MWA-120 ICs
- 1 7815 voltage regulator
- 2 1-uF tantalum capacitors, 35 volts
- 3 470-Ohm, ½-Watt resistors
- 2 2200-Ohm, ¼-Watt resistors
- 1 470-Ohm, ¼-Watt resistor
- 1 51-Ohm or 47-Ohm ¼-Watt resistor
- 2 .01-uF disc ceramic capacitors
- 2 J. W. Miller coils, L1 and L4, 49A678MPC, .60-.074 uH
- 1 J. W. Miller coil, L5, 49A347MPC, .250-.415 uH
- 2 J. W. Miller coils, L2 and L3, 49A537MPC, .393-.657 uH

Total cost is approximately $60.00.

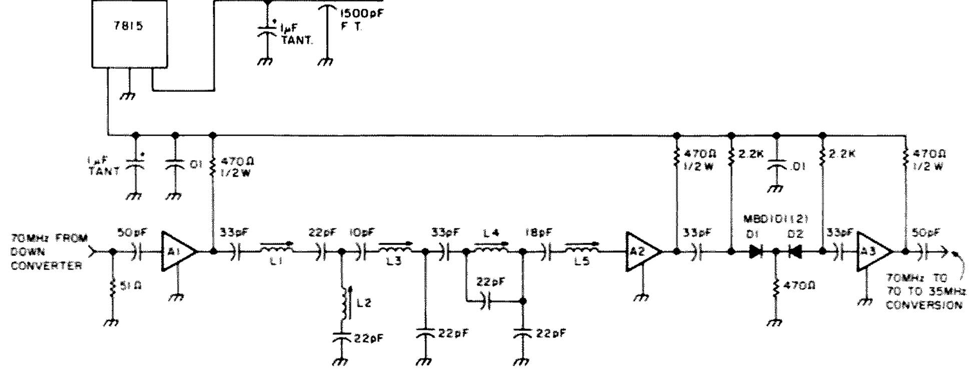


Fig. 2. 70-MHz filter/amplifier schematic.

audio and AFC-1 pickoff points are at the emitter of this transistor. The AFC-2 junction point is on the collector of this transistor. The de-emphasis filter also connects to the 2N2222 emitter, and then goes through an audio trap to the NE592 video amplifier.

The NE592 has complementary outputs, which makes it simple to provide video reversal (not all transponders use the same video polarity). The output of the 592 feeds the base of another 2N2222. The emitter of the second 2N2222 is ac-coupled to the base of a third 2N2222 whose base is clamped with a zener diode and a hot-carrier diode to keep the 30-Hz energy dispersal waveform from appearing at the video output. The 30-Hz component, if not removed, will wreck your vertical sync. The 1-volt video output is ac-coupled and terminated with a 100-Ohm resistor.

Construction

To make construction really simple, a PC board layout and parts overlay is provided. See Fig. 8. The PC board is double-sided G-10. The parts overlay is shown in Fig. 9.

For easiest assembly, install all resistors first and then the capacitors and chokes. Transistors are installed next, being sure that they are properly inserted. Power up the board and check the ouput of the voltage regulators for correct voltage before inserting the ICs. Save the ICs for last. You can use a socket for the NE592, but do not use a socket for the NE564.

Tune-Up

The joy of using the NE564 becomes evident when you get to the alignment procedure. Set the 1k pot and 10k pot at mid-position. Apply power. Adjust the 1k pot for 5 volts dc on pin 10 of the 564. Connect a frequency counter or grid-dip meter to the "VCO out" point on the board and adjust the variable capacitor for a 70-MHz vco frequency. Assuming that you have the rest of your system working, connect the output of the 70-MHz filter i-f amplifier board to the video demodulator board. With a video monitor attached to the video output, you should have satellite TV! Congratulations!

The final adjustment is made while watching video on your TV. Adjust the 10k pot for 1-volt video out or at least good contrast on your monitor. Now is the time to adjust the 1k pot on pin 10 of the 564. Monitor the pin 10 voltage while adjusting the pot. Changing

of infinite cleverness or wisdom you may enjoy when you recycle useless junk!

The Universal Circuit

Or you can build a fixed-frequency detector. The most popular circuit in use today is one using a single IC. Known by such names as the LM3065, CA3065, or MC1358, this simple chip is nothing more than a quadrature detector which forms the guts for most TV-set sound circuits. See Fig. 3. The subcarrier feeds a bandpass filter tuned to the appropriate frequency which in turn feeds the chip for detection and de-emphasis.

Deep in its heart of darkness, the chip amplifies the signal into limiting before it is detected. In addition, the chip also contains an electronic attenuator and an output driver amp. A variable resistor from pin 6 to ground controls the electronic attenuator. Minimum resistance gives maximum volume. The distortion specs on the amp are not too sweet so it is best ignored. Besides, you can get nearly 0 dBm out of the bare detector, anyway—more than enough to ionize the plastic transistors in any amplifier.

You can build one of these detectors in an evening, but there is a better way. Buy it already built! As I've mentioned before, regular TV sound detectors are just about the same thing, circuitwise, except that they are tuned to 4.5 MHz. They differ from satellite audio ever so slightly in frequency, de-emphasis, and bandwidth. Interestingly enough, the entire sound section for an RCA XL-100 TV contains just such a circuit on the small PC card seen in Fig. 4.

Build It Quick and Dirty

The XL-100 sound modules are available at most TV distributors. They cost about 15 dollars and are a bargain when you consider what your time is worth these days to build one from scratch. Order an RCA part number MAA001A.

The units come tuned to 4.5 MHz for TV sound. Just a few mods will make them tunable from 5 MHz to nearly 8 MHz. Change the value of C290 to 50 pF. Also change C295 to 25 pF. This will shift the unit from 4.5 MHz to about 6.5 MHz. Then solder a .01-μF capacitor from pin 13 on the chip to a ground trace. This sets the de-emphasis to 75 μsec.

Build a well-regulated supply the easy way by using a molded plug-in dc charger/power supply connected to a large-value capacitor and a 3-terminal regulator as seen in Fig. 5. Just be sure to include the capacitor on the output of the regulator or it will quickly lose its cool in the worst way.

Everything should fit into a small 2 × 5 box even if you use a soldering gun rather than a pencil iron. See Fig. 6 for an idea on layout. Use whatever connectors you have in your junk box. Nothing is critical except for the mandatory use of coax from the receiver to the unit. The tap-off in the receiver is simply the same place the other sound detectors connect, usually right after video detection.

Tune-up is easy. Use your ear and twist T299 and L299 until you hear sound. A better way is to feed your signal generator into the unit while looking at pin 9 on the chip with a scope. Once you see rf, back down the generator below limiting (done by the chip) and peak T299 and L299 for the frequency you want. If you can frequency-modulate the generator, by all means do so and set it for ±75-kHz deviation. Then look at the demodulated audio and adjust L299 for the best waveform. A THD analyzer can be used to improve the distortion specs with a variable resistor in parallel with C295 and L299 to lower the Q.

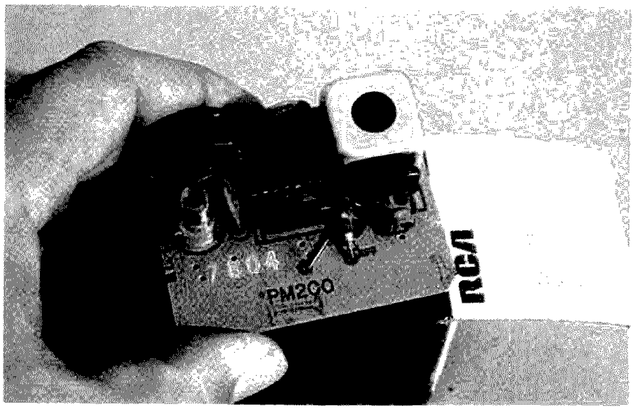

Fig. 4. Known by TV servicemen as the PM200, this small card holds nearly an entire TV-set sound section. It's a natural for cheap satellite audio recovery.

Next, align the bandpass-filter coils simply by peaking. You may not need the coils at all depending on the prefiltering done in the receiver. The ideal coil adjustment method is to first peak everything including L299. Then short the second coil with a 10-Ohm resistor (you'll need more umph from the rf generator) and peak again. Remove the resistor, back down the generator, and re-peak the second coil.

Bells, Whistles, and Distortion

If the subcarrier decoder is intended as a TV sound detector, you'd better leave the 50k volume-control pot in the circuit so that you can adjust audio drive to a subsequent rf remodulator. If you are feeding another amp, you could just as well forget the pot by grounding pin 10 on the board (pin 6 on the chip). This will set the output at maximum, about 0 dBm across 600 Ohms using a 12- to 16-volt supply.

You can save in the amplifier department, too. The amplifier for an RCA XL-100 is also available. Order MAN002A and use the circuit in Fig. 7 for intercon-

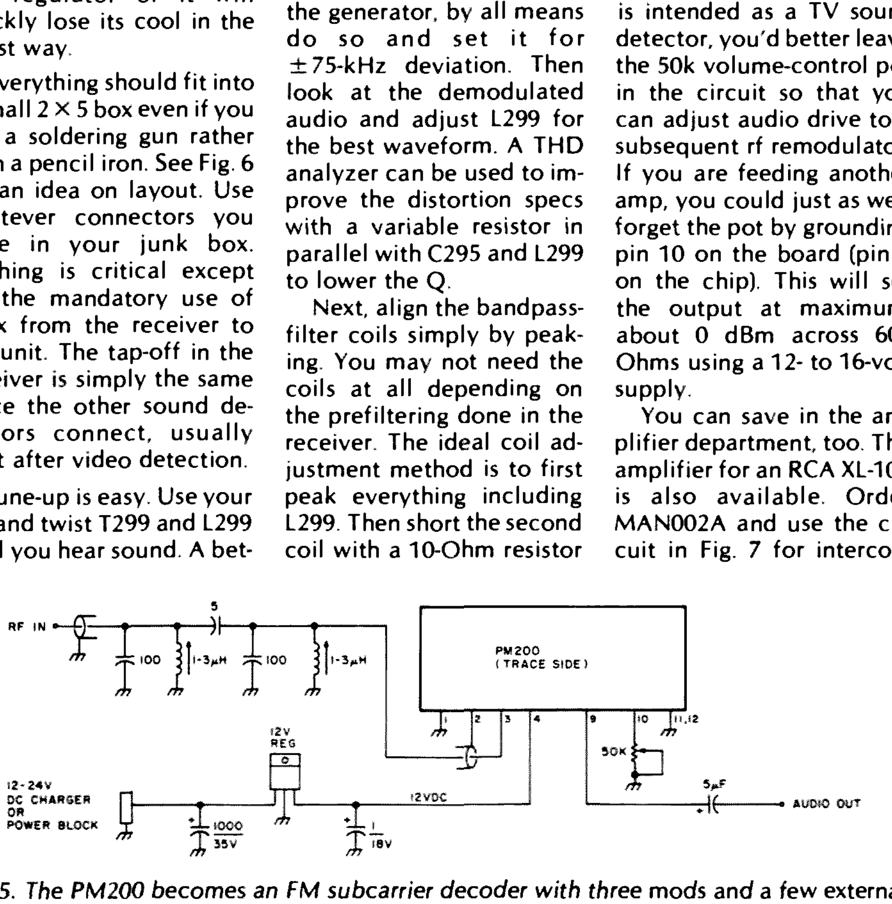

Fig. 5. The PM200 becomes an FM subcarrier decoder with three mods and a few external parts. Use your ear or an rf signal generator to tweak it into operation. Forget the input bandpass network if the receiver already has a high-pass filter for subcarriers.

the matching decoupling section.

Construction

Add one half inch to the calculated length to allow for exposing the center conductor so it can be connected to the other element. See Fig. 2. Cut the jacket, shield, and dielectric with one cut. A sharp knife or X-acto® miter saw should be used to make the cut. After all the elements are cut to length, then cut the jacket back three-eighths of an inch and tin both the center conductor and shield using a 25-Watt iron—too much heat will melt the dielectric.

Now that all parts are tinned, solder the parts together with a maximum of one-eighth-inch separation between elements. After completion, check for shorts by visual inspection as the antenna is at dc ground. Excess flux should be scraped off, but do not use any chemical flux remover as it can contaminate the dielectric. The whip on the top is connected to both the center and shield. The matching section is a quarter-wave coax stub shorted at both ends and a piston trimmer capacitor. See Fig. 3.

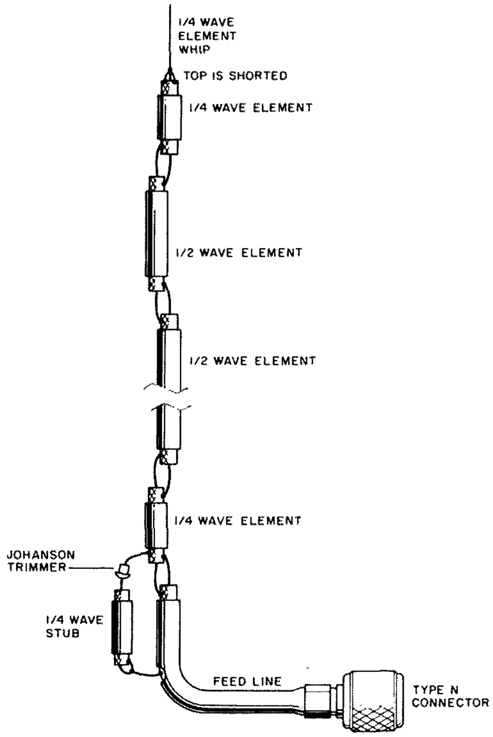

Fig. 3. 8 elements = 6 dB. 16 elements = 9 dB.

Tune-Up

Adjust the trimmer for minimum vswr. If the minimum is at one end of the trimmer, then adjust the spacing of the stub to feedline distance. One-eighth inch is normal for the spacing.

Housing

The antenna is housed in PVC pipe. The heavy wall is the one to use and it is also known as schedule 40 PVC. One-inch diameter can be used for either the 1241-MHz model or the 434 model, but if the antenna is to be mounted as a free-standing antenna, the 434-MHz housing should be tapered. This can be done with ¾-inch, 1-inch, and 1¼-inch pipe. The pipe may need to be heated to make a better fit. Pipe caps are used to keep the rain out of the housing and the bottom should be open so it can breathe. The antenna can be mounted one half wavelength from a mast for a cardioid pattern and the gain will increase 2 dB over that of an omnidirectional pattern. See Fig. 4 for the patterns.

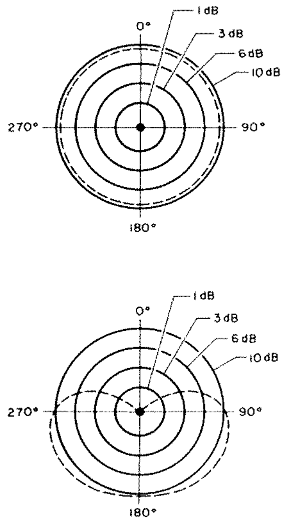

Fig. 4. (a) Omnidirectional pattern. (b) Cardioid pattern.

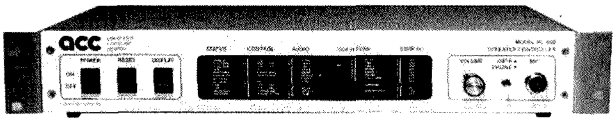
Conclusions

Construction time is one to two evenings. Take your time and you will have a better working antenna. The 434-MHz version has been in use for one year now on Mount Wilson and has survived all four seasons from 100 degrees heat to snow and ice. Many of these particular antennas in Los Angeles and San Diego have been built and used with the same results as I have obtained. Recently, a second 1241-MHz version was installed on Mount Wilson for the aural transmitter on the ATV repeater. It is identical to the one used for the visual transmitter and the results have been good.

Acknowledgements

I would like to thank Jay N6BDT for his help in testing the antenna, and also all others who helped me in this endeavor.■



Introducing A Whole New World Of Capability For Your Repeater . . .

- ☐ FLEXIBILITY, SECURITY-Remote configurability with non-volatile storage of command codes, ID and tail messages, tone characteristics, timing, and more
- ☐ QUICK, EASY, SECURE AUTOPATCH-Store/forward patch plus two autodialers
- ☐ FLEXIBLE LINKING-Supports synthesized remote bases
- ☐ VOICE RESPONSE TELEMETRY-Meter readback with natural sounding synthesized speech lets you monitor your site, gives users diagnostic information about their signals

Zepp and Sons

—an end-fed, ½-wave antenna

Stan Gibilisco W1GV/4
PO Box 561652
Miami FL 33156

You probably have some idea of what a Zepp antenna is. It's end-fed with open-wire line and has to be tuned using a transmatch, right? Well, Zepp is a nickname applicable to many kinds of antennas. Generally, any end-fed, half-wave antenna is a variation of the Zepp.

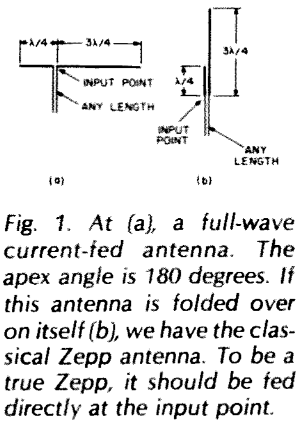

Fig. 1. At (a), a full-wave current-fed antenna. The apex angle is 180 degrees. If this antenna is folded over on itself (b), we have the classical Zepp antenna. To be a true Zepp, it should be fed directly at the input point.

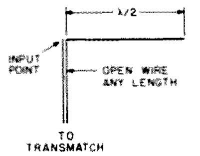

Fig. 2. The version of the Zepp most commonly used among hams. It operates at the fundamental and all harmonics.

How did they ever come up with a name like Zepp? How does the Zepp antenna work? Can you use a Zepp, or variation, to advantage at your station?

The True Zepp

The Zepp originated from the demand for an end-fed antenna that did not require a substantial ground to work against. At first thought, this might seem like an unrealistic idea. But it can be done.

Fig. 1 shows the evolution of the Zepp, so named because it was first used as an antenna dangled from a zeppelin! A full-wave antenna has a low resistive impedance when fed at a current maximum (a). Current feed of a full-wave antenna mandates that one side be 1/4 wavelength and the other side be 3/4 wavelength. The apex angle at (a) is 180 degrees, but smaller angles will work. The antenna will work even if the apex angle is zero degrees (b). When the apex angle is zero degrees, we in fact have a half-wave piece of wire fed at the end by a quarter-wave section of parallel-wire line.

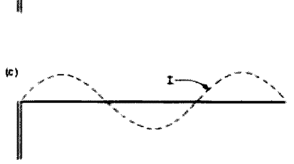

Fig. 3. Harmonic operation of the half-wave Zepp. At (a), operation on the fundamental (1/2-wave); at (b), second-harmonic operation (full-wave); at (c), third-harmonic operation (3/2-wave).

At the input point of the transmission line in Fig. 1(b), the impedance is a pure resistance of a very low value. The quarter-wave piece of line, formed from the folding over of the original full-wave antenna, acts like an impedance transformer, bringing a high impedance down to a low one.

How the Zepp Works

The radiating part of the Zepp is, of course, the half-wave part extending past the parallel-wire line. One end of the line is just left hanging. How can this work?

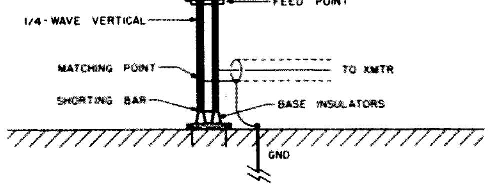

Fig. 4. The J-pole. The bottom end is shorted and the matching point adjusted for minimum swr at resonance. The height of the matching section in feet is 2.80/f, where f is given in MHz. The overall height of the structure is 700/f. This is a monoband antenna.

above utility lines. Also, some guy back in the 1700s already proved that thunderstorms contain electrical energy. There is no need for you to prove it again.

Conclusion

The Zepp is versatile because end feed is physically convenient. This results in some line radiation, but if the antenna is located wisely and cut to the proper length, this problem is not serious.

The Zepp may be operated at any harmonic, although the bandwidth tends to be narrow. As a rule, consider the useful bandwidth of a Zepp to be 50 kHz either side of resonance, whether it is operated on the fundamental or a harmonic. Example: A Zepp that is a half wavelength at 7050 kHz may be used between about 7000 and 7100, 14050 and 14150, 21100 and 21200, and 28150 and 28250 kHz. (Outside these ranges, the antenna will work, but there will be significant radiation from the feedline.)

Now dig out those old porcelain insulators (you *did* save them, didn't you?) and that 300-foot roll of stranded no. 14 copper wire you bought last year at Dayton for $1.50 and thought you could never use. Hang a Zepp someplace! ■

Notes

[1] For wire antennas, use the formula: length (feet) = 468/f, where f is given in MHz, for the length of a half wave. This is only approximate and may have to be pruned, but it represents the best average value.

[2] After the antenna has been cut according to the formula, you can find its resonant frequency by using a field-strength meter placed a few feet from the feedline near the transmitter. The resonant frequency is the frequency where the field strength is minimum, indicating minimum line radiation. Then, the antenna may be pruned until its resonant frequency is as desired.

The voltage at the end of the half-wave radiator is applied across a theoretically infinite impedance, which causes rf current to flow along the wire. It's kind of like shaking the end of a loose clothesline to make waves up and down the rope; although we never actually *pull* on the rope, the waves nevertheless occur along its length.

In theory, the Zepp is a balanced antenna because the impedance is infinite both at the free end of the line and at the terminated end. In practice, however, there is no such thing as an infinite impedance. The impedance at the free end of the line is *extremely* high, that at the terminated end is *very* high. They're a little different, and this unbalances the currents in the feedline. Consequently, the line radiates to some extent. This radiation can be minimized by ensuring that the impedance at the feedpoint is a pure resistance and is as high as practicable. This requires that the radiating part of the Zepp be *exactly* a half wavelength long,[1] and also that the antenna be placed as much in the clear as possible, to maximize the impedance at the ends of the radiating length of wire.[2]

Yet, even if we dangle this contraption from a zeppelin at 40,000 feet, it won't be perfectly balanced. The feedline will invariably radiate a little energy. A properly operating Zepp is not too bad about this—it's almost as good as a center-fed antenna.

The Usual Zepp

Most hams who use a Zepp have an installation something like that shown in Fig. 2. With this kind of system, a transmatch is necessary since we don't know what the impedance will be like at the station. This kind of Zepp will work at the fundamental frequency (the band where it's 1/2 wavelength) and all harmonic frequencies. At any harmonic, the Zepp has a current node at the feedpoint. Harmonic operation of the Zepp is shown in Fig. 3.

The Zepp is somewhat temperamental about departures from its resonant frequency. Even a tiny change in frequency will move the current node away from the feedpoint—either out onto the radiating part of the antenna (frequency too high) or down into the transmission line (frequency too low). But the node at the loose end of the line cannot move. The result: line radiation! The Zepp is a narrowband antenna.

What if you have no transmatch and do not exactly feel like running out to your local ham shop and plunking down a hundred dollars or so to buy one of those fancy things they're selling nowadays? Can you still use a Zepp? Definitely. Fig. 4 shows one way to get a good match to 52- or 75-Ohm coaxial cable. Fig. 5 illustrates a second method. When the correct matching point is found, the swr is 1 at resonance.

Vertical Sans Radials

Of course, we can orient a Zepp in any direction we want. Figs. 4 and 5 show two vertical Zepp antennas. The antenna in Fig. 4 is often called a J-pole and is fairly common at VHF. But it is practical down to about 20 meters, and if you're ambitious, you might want to try building one for 40. In Fig. 5 is a method of feeding a half-wave radiator. This is definitely practical down to 40 meters. Both of these schemes constitute Zepp feed. Both of these antennas are monobanders, though, because of the matching technique used.

These antennas do not need any radial system. In both instances, the base impedance is very high and thus ground loss is kept to a minimum. Adding radials to the antenna in Fig. 5 will improve its performance, because of the gain resulting from the image signal. (This will provide the equivalent of a 2-element collinear.)

Other Zepps

A half-wave sloper may be fed at the end instead of in the center. The performance of the antenna will be the same in either case. This is shown in Fig. 6(a).

Zepp feed, because of its convenience, allows an exotic method of getting the antenna up in the air. This is shown in Fig. 6(b). The feedline should be TV-type twinlead, in order to minimize the weight, and the kite may have to be pretty big. But this idea has been used successfully on 160-meter endeavors when the wind is strong enough! One word of caution: Make sure the system is not flown

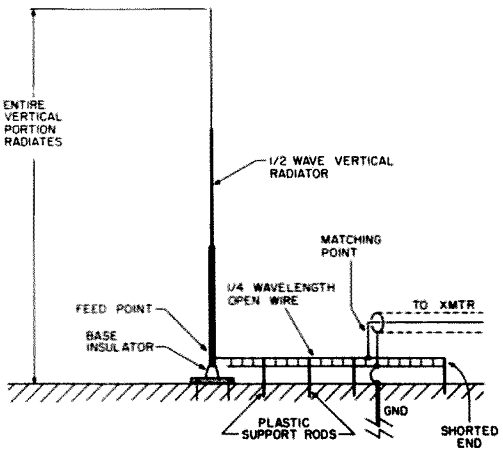

Fig. 5. Zepp feed for a half-wave vertical. The length of the open-wire matching section in feet is 275/f. (Don't use TV twinlead!) Adjustment of the matching point is required; a good starting point is 1/6 of the way from the shorted end to the antenna end of the matching section for this antenna and for the J-pole.

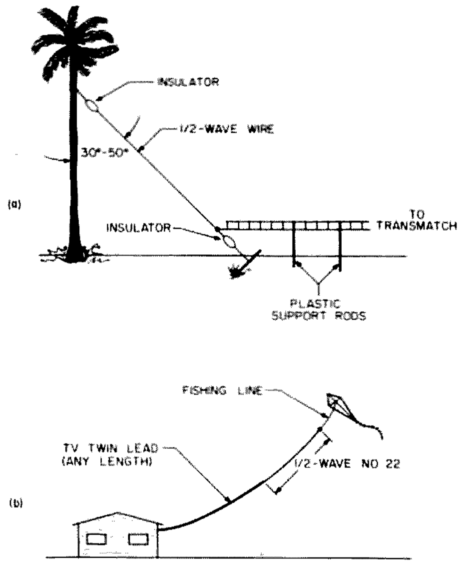

Fig. 6. At (a), end feed for a half-wave sloper. At (b), well, end feed for a half-wave sloper! These antennas will work at the fundamental and all harmonics.

LUFKIN TX
MAY 14-16

The Region Four Air Force MARS will hold their annual convention on May 14-16, 1982, at the Ramada Inn, Lufkin TX. Friday night there will be an administrative meeting of all headquarters personnel and all Region Four officials, and Saturday there will be a series of programs. A banquet will be held on Saturday night. For further details, please contact Ed Langston AFA4KH, Convention Chairman, 1123 Sayers Street, Lufkin TX 75901.

CADILLAC MI
MAY 15

The 22nd annual Swap Shop & Eyeball QSO will be held on Saturday, May 15, 1982, from 8:00 am to 4:00 pm at the Wexford Civic Arena, US 131 North, Cadillac MI. Tickets are $2.50 and 8-foot tables are $4.00. There will be prizes, plenty of parking, and lunches available. Talk-in on 146.37/.97. For further information, contact Wexaukee Amateur Radio Association, PO Box 163, Cadillac MI 49601-0163.

DURHAM NC
MAY 15

The Durham FM Association will hold the annual Durhamfest on May 15, 1982, at the South Square Mall, US 15-501 south, Durham NC. Admission is $3.50 with no additional charge for tailgating or dealers' spaces. Features will include prizes and a flea market. Motels, a restaurant, facilities, tables, and power will be available. Talk-in on 147.825/.225. For more information, write Durhamfest, Box 777, Hillsborough NC 27278.

ROGERS AR
MAY 15

The Northwest Arkansas Amateur Radio Club, Inc., will hold its 2nd annual hamfest/swapmeet on Saturday, May 15, 1982, from 8:00 am to 4:00 pm at the Community Building (Old Armory), US Hwy 71, Rogers AR. Commercial exhibitors' and flea market tables and spaces are free. Doors will open at 6:00 am for setup. Main prize tickets are 3 for $5.00 or $2.00 each and prizes include a complete Kenwood station consisting of TS-130S, ac power supply, and MC-50 mike. There will also be door prizes, free parking, and programs, including MARS, DX, and Skywarn. Talk-in on 146.16/.76 or 146.52. For more information, write Mary Webb KA5HEV, PO Box 338, Prairie Grove AR 72753, or call (501)-846-2847.

BATON ROUGE LA
MAY 15-16

The Baton Rouge Amateur Radio Club will hold its annual hamfest on Saturday and Sunday, May 15-16, 1982, at Catholic High School, 855 Hearthstone Drive, Baton Rouge LA. There will be swap tables, dealers' exhibits, technical forums, and activities for the non-ham wives and children. Talk-in on .19/.79 and .52 simplex. For further information, write BRARC, PO Box 4004, Baton Rouge LA 70821.

ATHENS OH
MAY 16

The Athens County ARA annual hamfest will be held on Sunday, May 16, 1982, from 8:00 am to 4:00 pm at the Athens City Recreation Center, East State Street, Athens OH. There will be a free flea market for electronics-related items on a large paved area and some indoor space available on a first come, first served basis. Setup is at 7:00 am. Food, free parking, and several nearby restaurants will be available. Tickets are $1.00 in advance and $2.00 at the gate. Talk-in on .34/.94. For further information, send an SASE to ACARA, PO Box 72, Athens OH 45701, or phone Joe Follrod WB8DOD at (614)-797-4874.

MARSHALL MO
MAY 16

The Indian Foothills Amateur Radio Club will hold its 7th annual hamfest on May 16, 1982, at the Saline County Fairgrounds building, Marshall MO. Tickets are $2.00 each or 3 for $5.00 at the door, or 5 for $5.00 in advance. There is no charge for tables but reservations are requested. Registration will be at 8:00 am and coffee and breakfast rolls will be available from 8:00 am to 10:00 am. Lunch (all you can eat) will be at 11:30 am. The drawing will be held at 2:30 pm with a first prize of a KDK 2025 Mark II. Talk-in on .52, .28/.88, and 147.84/.24. For additional information and advance tickets, contact Jim Little KB0DA, 405 E. Rosehill, Marshall MO 65340, or call (816)-886-8583 after 5:00 pm, or K0BVB at (816)-886-2837.

EASTON MD
MAY 16

The eighth annual Easton Amateur Radio Society Hamfest will be held on May 16, 1982, rain or shine, from 8:00 am to 4:00 pm at the Easton Senior High School cafetorium, Rte. 50, just south of Easton at mile marker 66. The donation is $2.00 with an additional $2.00 for tables or tailgaters. Talk-in on .52 and 146.445/147.045. For more details, write Van Herridge WB3HGQ, Box J, St. Michaels MD 21663 or Easton Amateur Radio Society, Inc., Box 781, Easton MD 21601.

WEBSTER MA
MAY 16

The Eastern Connecticut Amateur Radio Association will hold its 8th annual flea market and auction on Sunday, May 16, 1982, starting at 9:00 am, rain or shine, at the Point Breeze Restaurant, Webster Lake, Webster MA. Admission is $1.00 and table reservations are $5.00 in advance or $7.00 at the door. Food and drinks will be available as well as free parking. The auction will be held at 1:00 pm. Talk-in on 147.885/.285 K1MUJ and 146.52. For reservations and additional information, contact Dick Spahl K1SYI, Lake Parkway, Webster MA 01570, or phone (617)-843-4420 after 7:00 pm.

WABASH IN
MAY 16

The Wabash County Amateur Radio Club will hold its annual hamfest on Sunday, May 16, 1982, from 5:00 am until 4:00 pm at the Wabash County 4-H Fairgrounds, Wabash IN. Admission will be $3.00 at the gate or $2.50 in advance. There will be plenty of food and parking available, as well as free overnight camping on Saturday. Talk-in on 147.63/.03 or 146.52. For tickets or more info, send an SASE to Dave Spangler N9ADO, 45 Grant Street, Wabash IN 46992.

EVANSVILLE IN
MAY 16

The Tristate Amateur Radio Society (TARS) will hold its annual hamfest on Sunday, May 16, 1982, beginning at 6:00 am CDT at the Vanderburgh County 4-H Center, Evansville IN. Admission is $2.00. Tables will be available in the air-conditioned indoors. An outdoor flea market will also be featured. Talk-in on 147.75/.15 and 146.19/.79. For additional information and table reservations, contact Hal Wilson WB9FNN, RR 8, Box 427B, Evansville IN 47711.

WRIGHTSTOWN PA
MAY 16

The Warminster Amateur Radio Club will hold its annual hamfest on Sunday, May 16, 1982, from 7:00 am to 3:00 pm at the Middletown Grange Fairgrounds, Wrightstown PA, near Philadelphia. Admission is $3.00 at the gate with an additional $2.00 for each 8-foot seller's space. Children and spouses will be admitted free. If pre-registered by May 1, 1982, the admission fee will be $1.00 less. Door prizes will be awarded every half hour beginning at 9:00 am. Talk-in on 147.690/.090 and 146.520. For more information, write PO Box 113, Warminster PA 18974, or call Bill Scott KA3CHB at (215)-249-0568 after 6:00 pm.

FRESNO CA
MAY 21-23

The Fresno Amateur Radio Club, Inc., will hold its 40th annual hamfest on May 21-23, 1982, at the Hacienda Inn, Clinton and Highway 99, Fresno CA. The full advance registration cost is $20.00. On Friday, activities will include registration, a golf tournament, and wine tasting; on Saturday, swap tables, commercial exhibits, a luncheon program, a CW contest, MARS meetings, a transmitter hunt, a No Host Cocktail Hour, and a banquet with speaker, Dr. Henry Richter; on Sunday, a

WPSS Breakfast. Talk-in on 146.34/.94. For advance registration or more information, contact the Fresno Amateur Radio Club, Inc., PO Box 783, Fresno CA 93712.

GORHAM ME
MAY 22

The Portland Amateur Wireless Association and the Southern Maine University Radio Club will hold their annual flea market on May 22, 1982, from 8:00 am to 4:00 pm (inside if it rains) at the Gorham ME campus. The cost is $1.00. Food will be available. Talk-in on 146.73R and 146.52S. For additional information, write John Taylor N1SD, 44 Milton Street, Portland ME 04102, or call (207)-773-2651.

GREEN BAY WI
MAY 22

The Green Bay Mike and Key Club will be holding its seventh annual swapfest on Saturday, May 22, 1982, from 8:00 am to 3:00 pm at the Norwood School, Norwood and Ninth, Green Bay WI. Admission is $1.50 in advance by May 1st, and $2.00 at the door. Table space is $2.00, and there will be one free admission for every 2 tables bought. Door prizes will be given away and food and beverages will be available. Talk-in on 147.72/.12 and 146.52. For more information, contact Bob Duescher KA9BXG, 1011 13th Avenue, Green Bay WI 54302 or phone (414)-497-7880.

WEYMOUTH MA
MAY 22

The South Shore Repeater Association will hold its ham radio/electronic/computer flea market on Saturday, May 22, 1982, at Weymouth South High School Cafeteria, 300 Pleasant Street, Weymouth MA. Admission is $1.00 for each buyer and tables are $5.00 in advance or $8.00 at the door. Doors open for sellers at 9:00 am and for buyers at 10:00 am. Food and refreshments will be available. For directions or table reservations, please contact SSRA, c/o David Newman, PO Box 447, Abington MA 02351.

KNOXVILLE TN
MAY 22-23

The 1982 ARRL Delta Division Convention and the sixteenth annual Knoxville Hamfest will be held on Memorial Day Weekend, May 22-23, 1982, at Bearden High School, Knoxville TX. Forums will be on the future of amateur radio, DXCC, the CQ 5B-WAZ program, fast-scan TV, computers and amateur radio, and the ARRL. Other activities include programs for non-ham ladies, a shuttle bus to the World's Fair, an indoor and outdoor flea market, an exhibit area, and the verifying of QSL cards by Don Search W3AZD and Bob May K4SE. Both 4-land QSL bureaus will be in attendance and cash prizes will be offered in the Ron McKean Memorial CW competition. For more information, please write Delta Division Convention, c/o Ray Adams N4BAQ, 5833 Clinton Highway, Suite 203, Knoxville TN 37921, or phone (615)-688-7771 (days) or (615)-687-5410 (nights).

HARTWELL GA
MAY 22-23

The Anderson, Hartwell, and Toccoa Amateur Radio Clubs will hold the 4th annual Lake Hartwell Hamfest on May 22-23, 1982, at the Lake Hartwell Group Camp, located on Highway 29, 4 miles north of Hartwell GA. Features include free admissions, free camping, and free flea market space. Activities include a left-footed CW contest, horseshoes, bingo, and many other activities for the whole family. Fishing, swimming, and camping are available on the site. The campground will open at 6:00 pm Friday and the main prize drawing will be held at 2:00 pm Sunday. Talk-in on 146.19/.79, 147.93/.33, and 146.895/.295. For further information, contact Ray Pettit WB4ZLG, Rte. 1 Dooley Drive, Toccoa GA 30577.

BOULDER CO
MAY 23

The Rocky Mountain VHF Society will hold the annual spring hamfest on Sunday, May 23, 1982, from 9:00 am to 3:00 pm, rain or shine, at the Boulder National Guard Armory, 4750 North Broadway, Boulder CO. The admission donation will be $2.00 per family and there is no seller's charge. The gates will open for sellers at 8:00 am and they suggest you bring your own table. The door prizes will include a synthesized FM transceiver, and extra raffle tickets will be available. In addition to the big ham swap, there will be technical demonstrations and seminars, covering topics such as fast-scan ham TV, microwaves, satellite communications, etc. Food and drink will be available. Talk-in on 146.16/.76 and 146.52. For more information, contact Richard Ferguson KA0DXM, 1150 Albion Road, Boulder CO 80303, or phone (303)-449-2871.

NATCHEZ MS
MAY 23

The Old Natchez Amateur Radio Club (ONARC) will hold its hamfest on Sunday, May 23, 1982, at the Natchez Convention Center, Natchez MS. Doors will open at 8:00 am and there will be food available as well as free admission and free swap tables. Talk-in on 146.31/.91. For further information, contact S. W. Gates N5AXV, PO Box 203, Natchez MS 39120.

ISLIP LI NY
MAY 23

The Long Island Mobile Amateur Radio Club will hold the ARRL Hamfair '82 on May 23, 1982, at the Islip Speedway LI NY. General admission is $2.00 and $5.00 per car space will be charged for exhibitors. Food and refreshments will be available at the track. There will be door prizes and special prizes drawn all day from 9:00 am to 4:00 pm. Talk-in on 146.85 (a 4Z PL will extend your range into New York City). For more information, call Sid Wolin K2LJH at (516)-379-2861, or Hank Wener WB2ALW at (516)-484-4322 in the evening.

BURLINGTON KY
MAY 23

The Northern Kentucky Amateur Radio Club will hold its annual Ham-a-rama on Sunday, May 23, 1982, at the Burlington Fairgrounds, Burlington KY (off 275, Burlington-Florence exit). Individual tickets are $4.00, family tickets are $6.00, and each ticket entitles you to the major prize drawing at 4:00 pm. First prize is a Kenwood low-band TS-130S or $500, second prize is a Kenwood HC-10 station clock, and there will be a special raffle for an Icom 2AT. Features will

Surviving the Unthinkable

—part I: the ham's role

Today they hauled out the last of the Civil-Defense supply cans from our office building. It wasn't much of a loss, however, because long ago the familiar drab green cans with their black lettering had been emptied of their contents. Once they had stored food, water, medical supplies, radiation-monitoring equipment, clothes, etc., enough material for several hundred people to survive for two weeks after a worldwide nuclear holocaust.

The fallout shelter sign is a symbol of protection which is now giving way to crisis relocation plans.

But the food grew rancid and the other materials deteriorated. With several reorganizations of the building, the cans constantly were reshuffled into corners until, finally, there was no other place to put them but out with the trash. Tonight they most likely grace the garage of a member of the maintenance staff who saw them as too good to discard and recovered them to use for workshop trash, discarded cuttings from his table saw, or some such refuse.

The case here is common. The once-familiar sight of fallout shelter supplies gracing the basements of public buildings has all but disappeared. Only a few of the once-common fallout shelter signs remain. Most likely, if you care to check a building displaying a shelter sign, you will find plenty of shelter and no usable supplies.

So, what would happen if our nation's 225 million people suffered an attack by a nation using nuclear warheads? Are we totally unprotected? Out of luck? Frankly, according to civil-defense planners, people heading for those old-style shelters might be out of luck, anyway. The shelters are often located in downtown areas of large metropolitan areas. With a direct hit to one of these cities, it is very likely that the shelter would provide as much protection to its occupants as no shelter at all. Cities where this problem is expected to occur are shown

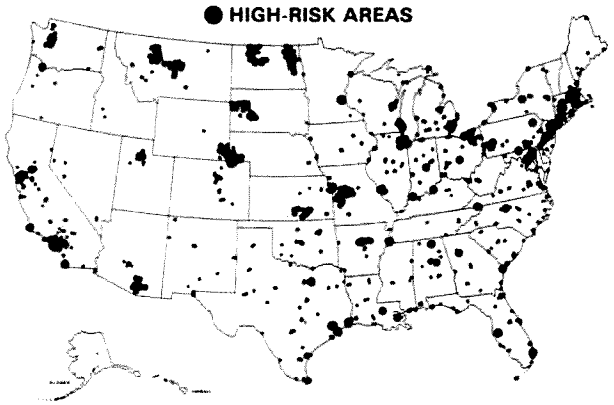

Fig. 1. The dots here represent possible high-risk areas which require crisis relocation plans.

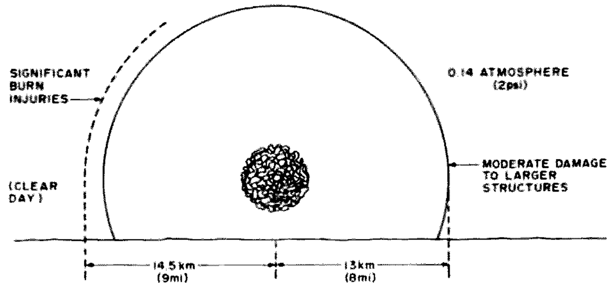

Fig. 2. Expected effects of 1-megaton air blast.

in Fig. 1, which is a map of cities most likely to receive direct hits in an all-out nuclear war.

The idea of these home cities being targets of some foreign nuclear power is not a pleasant thought. But in a world of increasing tensions, there no doubt will be an increased interest in our praying for peace, and also preparing for our own personal defense in the event our world leaders some day fail to keep the peace.

As an alternative to hiding in big-city shelters, planners suggest that it may be better to move people out of the crucial areas where devastation is most likely to occur. (Fig. 2 shows the sphere of effect for each 1-megaton device.) This plan is apparently patterned after a Russian plan discovered several years ago.

According to a recent publication of the Federal Emergency Management Agency, which now handles civil defense, the new plan is as much a negotiation plan as anything. They feel that in a game of superpower brinksmanship, where each side will see just how far the other will go before "pushing the button," the Russians would most likely evacuate their cities as a defense mechanism before launching an attack on us. Naturally, the planners feel our intelligence sources would let us know of the evacuation. At that point, we would rely on our country's availability of rapid transit and family cars to completely evacuate before the Russians do. We would then declare that since we're safe and they're not, they should back off and forget about blowing us to oblivion.

There are some good points about the plan. It is true that the United States has great versatility due to our widespread use of private cars, while the Russians cannot afford to have a car in every garage and would need to rely on trains, buses, and "marching routes" to move their people 30 to 200 miles from major cities. An illustration of their plan is shown in Fig. 3. The weather, however, complicates survival, as shown in Fig. 4.

Calculating the cold hard facts and the alternatives of attack plans, civil-defense authorities in the US figure that if the Russians attacked before evacuating, they would lose about 100 million civilians. On the other hand, if they evacuate first, they would lose a mere 20 million.

A non-classified Federal Emergency Management Agency report issued in October, 1980, states five key points about a Soviet attack strategy.

"1) The Soviets probably have sufficient blast-shelter space in hardened command posts for virtually all of the leadership elements at all levels (about 110,000 people).

2) With a few hours of warning or less, the Soviets would suffer over 100 million casualties, but a large percentage of the leadership elements probably would survive.

3) With 2 or 3 day of preparation, the Soviets would suffer less than 50 million casualties.

4) With a week (or more), they would suffer casualties in the low tens of millions.

5) Therefore, the critical decision to be made by the Soviet leaders in terms of sparing the population would be whether to evacuate cities. Only by evacuating the bulk of the urban population could they hope to achieve a marked reduction in the number of urban casualties."

The same reasoning applies to the United States. The most horrifying part of the statistics is that at the very least we're talking about tens of millions of lost lives. And that doesn't count radiation sickness, burns, exposure, starvation, etc.

The United States system was scheduled to be in place for most all cities during 1981. Under the system, planners believe that 80% of our population would survive to rebuild. Again, they do not estimate the aftereffects of such a disaster on the survivors of any nation.

Even after the plans are completed, there will be much additional work to be done: Shelters need to be constructed; managers need to be trained; tests of the system must be made, followed by evaluation of the tests and redirection based on the results of the tests.

Amateur radio is not mentioned in the FEMA publication sent to me regarding the crisis relocation plan. The response I received from an FEMA official states, "Those amateur radio operators who operate with Radio Amateur Civil Emergency Services (RACES) are still a very important part of civil preparedness. RACES licenses as such are no longer being issued by the FCC, but each RACES operator uses his own call letters. However, these persons must be recognized as part of the civil-preparedness organization in order to operate during emergencies under the auspices of RACES. Any RACES planning should be done with your own state of Iowa and the FCC."

Such planning is of little consolation to the residents of a state when they find out that nearly all of the state's (Iowa) 4,000 hams cannot operate, and the few licensed to operate the state's RACES station left the state one day ahead of a nuclear attack.

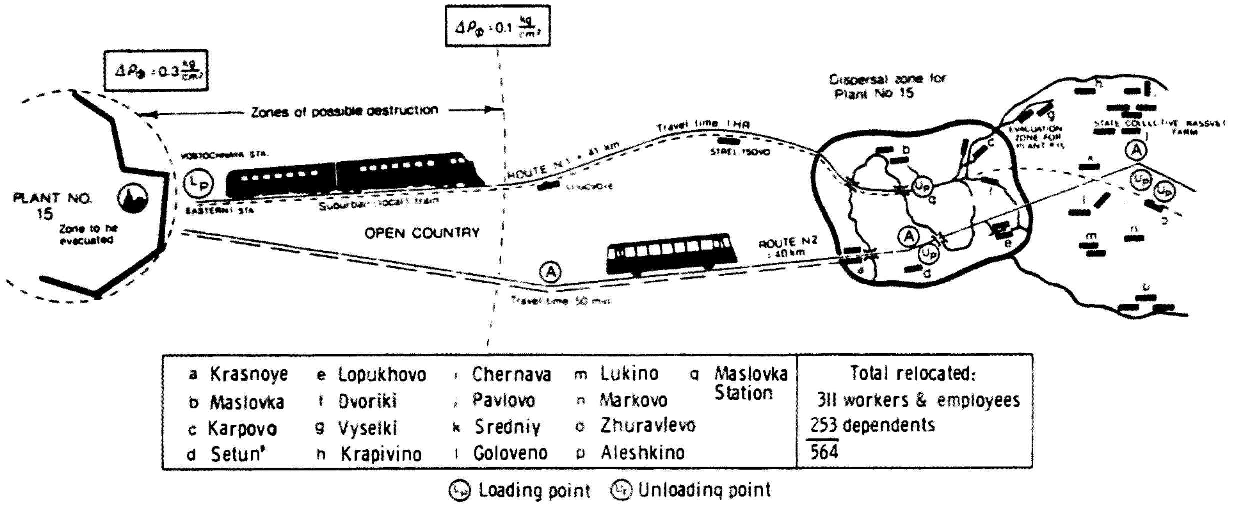

Fig. 3. According to the Federal Emergency Management Agency, this diagram shows Soviet plans for a crisis relocation program. The plan calls for dispersal of the population and daily commuting of workers to their places of employment.

By comparison, the May, 1980, issue of *73 Magazine* carried an article which described amateur activities when about 300,000 people came to Des Moines, Iowa, for an afternoon visit with Pope John Paul II. More than 150 local and statewide amateur radio operators provided excellent health and welfare services that day. The ratio of ham operators to population was about one amateur station for every 2,000 people. A substantially greater ratio was provided in areas where the sick and invalids were.

The situation in Des Moines was perhaps the best possible test of a crisis relocation program anywhere in the world since planners considered the notion of relocating hundreds of thousands of people. It was a complex program which was not easily undertaken. But on the specific point of supply of amateur radio operators, if the same ratio of amateur radio stations to population were applied to a national crisis-relocation program, *one out of every three* amateur radio stations in this country would need to be on the air in some assigned duty all the way from two meters through 160 meters. CW, FM, and SSB, in hundreds of orderly, planned, and tested networks, would be needed.

It is extremely unlikely that the present RACES system could come close to meeting the needs. As of December, 1979, there were only 610 officially licensed RACES stations on the FCC's books. We would need no less than 112,000 dedicated patriotic and very brave volunteers and their equipment.

The time is definitely here for amateurs to approach their local civil-defense authorities and the FCC to have this now-sophisticated service available on a widespread basis to every interested amateur radio operator in the event of a national emergency. Amateur radio is the only service which can provide a most-reliable communications system under severe circumstances when, for example, the entire telephone system would be rendered totally useless, merely because major switching locations would no longer exist!

Fig. 4. This is one of many possible distributions of fallout from a nuclear attack on the United States. The actual distribution would, of course, depend on the location and number of actual strikes and weather conditions.

Ham radio operators should be encouraged to improve their Morse-code capabilities, because under such strenuous situations, when even an amateur system may reach its peak in traffic-handling capabilities, every cycle of bandwidth of spectrum space is vital to the proper completion of the task. Currently, only CW operation can offer a bandwidth of just a few hundred cycles.

Right now, none of us, in our wildest dreams, can imagine how horrifying the world would be after a nuclear war. Our surviving population would need all the possible assistance that could be mustered, including medical supplies, food, and shelter, to name only a few. The existence of the top-notch amateur system like the one we now have could be the single most important item and could provide the key to our success.

In part II of this article, I will provide some details on just what can be done at each of our ham stations to lessen the danger to our communications systems. Some methods are simple, others incredibly expensive, but all of us can do something. ■

AWARD DIRECTORY

Countless letters and phone calls have been received regarding a proposed award directory, supposedly being sponsored by this magazine. To set the record straight and to avoid any further confusion, allow me to say that such a *73* publication just does not exist. That, of course, does not mean one will not be available in the distant future!

To attempt such an endeavor, the compiling of precise and up-to-date information becomes paramount and obviously the most difficult task. Unfortunately, too often, the author of such a publication has to be at the mercy of the various amateur radio clubs and organizations to provide him with the necessary input to make such a volume a reality. However, due to the apparent lack of interest of so many to submit information about their respective awards programs, we have almost discounted the idea altogether. Those who are theory-oriented will understand that no input is directly proportional to negative output!

However, to preserve the well-known Wayne Green tradition, "never say die," another attempt will be made to remuster the readership for their help to fill this void in our award files. We could use data on any award program you or your local club may be sponsoring, as well as any information regarding other award programs you may be aware of.

When you forward the various rules for each award, be sure to include an original of each award certificate so that it may be published in its entirety. After all, this is free advertising, ladies and gents! Don't you realize the exposure you'll be getting? The fact is, you will not have to pay $1500 per page as all advertisers have to just to get their message across to the readers. Take advantage of this unbelievable offer which only Wayne Green himself could extend to the readers of the most popular magazine in the hobby!

Send your award program rules and original award certificates directly to: Awards Directory, Attn: Bill Gosney KE7C, 2665 Busby Road, Oak Harbor WA 98277. Do not delay—send me your input today. Then, over the months ahead, perhaps we can put together the directory you've all been waiting for.

INTERNATIONAL AMATEUR RADIO SOCIETY

The International Amateur Radio Society (IARS) is an achievement, educational, public service, and amateur radio honor fraternity. It is the parent organization for the International Certificate Hunters Club (CHC), the International Shortwave Listeners Certificate Hunters Club (SWL-CHC), the International Amateur Radio Journalistic Society (IARJS), and the International Flying Hams Club (FHC), along with many affiliated subdivisions worldwide called either chapters or amateur radio associations.

The IARS publishes the *International Amateur Radio Society Annual*, which incorporates *The Directory of Certificates and Awards*, copyrighted internationally. The IARS also publishes the newsletter *Dialog*, through the IARJS, and the newsletter *Xtra*, the official house organ which reports news, special events, DX forecasts, and other items of interest to all members.

Through the CHC, the IARS sponsors many operating events, community services, achievement awards, and on-the-air nets. The IARS and its affiliates do not engage in partisan politics, but do take interest and action with regard to matters concerning the world's radio amateurs. It seeks to assist and cooperate with the many national amateur radio organizations (such as the ARRL, RSGB, JARL, etc.) in nations the world over. Although we may not always agree with what or how they do things, we acknowledge their efforts and lend them our support and participation.

The purposes of this organization are:

- to create and maintain an international communications system composed primarily of on-the-air amateur radio networks for all amateurs;
- to institute educational training programs and activities designed to advance the radio amateur's operating proficiency and technical knowledge, with emphasis on on-the-air gentlemanly conduct and compliance with the intent and interest of applicable national regulatory laws;
- to institute worldwide educational programs promoting improved human relations, international goodwill, and fellowship among men and women everywhere, without restriction or discrimination as to race, creed, color, national origin, political views, or religious belief;
- to promote the concept that shortwave listeners (SWLs) are fraternal kin to licensed amateurs and should be included in their programs and affairs;
- to promote the general welfare and survival of amateur radio as established under the International Communications Treaty;
- to publish educational books, magazines, newsletters, and literature in fields relating to international amateur radio; and
- to provide a comprehensive awards program, through the CHC, and to encourage and document the communication skills displayed by licensed radio amateurs and shortwave listeners.

The IARS, IARJS, CHC, SWL-CHC, and the FHC were created by Clif Evans K6BX in 1960 and have been protected as part of the copyrighted works of the Directory of Certificates and Awards. At the time of OM Clif Evans' death, the IARS, IARJS, CHC, SWL-CHC, and the FHC, along with 100 chartered, affiliated subdivisions called either chapters or associations, had over 22,000 members on the rolls, representing over 250 countries from all six continents.

They are making every effort possible to contact all of the members they have lost touch with since the death of Clif Evans and the closing of the old headquarters. Individual notification has been sent to each member via the bureau, and new club literature has been sent (via air mail) to all previous officials and office holders along with many national organizations and radio clubs around the world.

They look forward to all of their members around the world returning to active status.

The *International Amateur Radio Society Annual* is a yearly publication containing operating information and technical data, schedules of coming events of interest to the amateur community, net listings, DX tips, and much more. Included in the *IARS Annual* is *The Directory of Certificates and Awards*, the most comprehensive digest and guide to award-hunting ever offered to the amateur. The *IARS Annual* is also the organization's yearbook, offering a retrospective view on the past year and a look into the coming year, complete with IARS information on rules, codes, membership listings, and other items of interest to both the membership and amateurs at large.

The *IARS Annual* is published, revised, and updated annually in November, and covers in depth those topics not found in other handbooks. No amateur radio library is complete without it!

IARS Divisions Defined

IARJS: an international organization that provides a free and uncensored outlet for ideas, opinions, and proposals on behalf of amateur radio, through articles submitted by its members. These articles appear in the IARJS newsletter, *Dialog*, which provides its contributors an opportunity to inform radio amateurs throughout the world of conditions and situations affecting amateur radio. *Dialog* is a forum in which journalists and editors from around the world can exchange thoughts, ideas, and opinions on all matters concerning the future of amateur radio.

CHC: an international organization created to maintain an international communications system composed primarily of on-the-air amateur radio networks for all amateurs. The CHC also provides a comprehensive awards program and a vehicle for the procurement of awards from the many organizations around the world. Through its

system of networks, it provides the availability of contacts necessary for the achievement of these awards.

SWL-CHC: a mirror image of the CHC. SWL-CHCers seek the same achievement as radio amateurs except on a heard basis. All radio amateurs are also SWLs in half of all they do on the bands and are invited to participate in this division. The SWL-CHC also can provide the callsign necessary for QSLing through the bureau.

FHC: self-explanatory. Membership is available to any licensed radio amateur or SWL who holds, or has ever held, any nature of pilot's license or designation: aircraft, lighter-than-air vehicle, space, or glider.

Net Activity

CHC nets are 10, 15, 20, 40, and 75 meters as the demand dictates. Some of our nets are: CHC DX net, 0200 to 0500 UTC, 14.298 ± QRM, daily; CHC DX net, 1900 to 2200 UTC, 21.370 ± QRM, daily; and CHC Pacific family hour, 0000 to 0300 UTC, 21.370, daily.

Old CHC/New CHC

If you were familiar with the previous organization under Clif Evans K6BX, you will notice that they have instituted some drastic changes in both the way the club is handled and its value system. The new organization bears little resemblance in many areas to its predecessor, and they are sure you will find the changes to your liking. It is a blend of old and new and should be worthy of your review.

Membership is not a requirement for participation in either the awards program or any net activity. Membership is available with each division independently. Inquiries regarding membership are solicited. A bona fide interest in amateur radio is the only essential qualification (unless otherwise specified). When membership is attained, a membership number is issued which one holds *forever* regardless of change in name, call, QTH, class or license, or status of membership. Membership numbers and certificates are issued independently by each division. Membership in one division does not constitute membership in another.

Dues are payable during the first month of each year, January 1-31, following initial joining. Failure to pay dues will result in the member status being changed to inactive. Inactive members do not receive the newsletters, special club services, or voting rights when applicable. Inactive members always retain their original number. A member can go inactive in one division and still stay current in another. Payment of only present year's dues (not past) will restore any member to active status.

Newsletters are included with each membership, but are only available to members on active status. Articles are solicited from the members. They welcome information on all subjects pertaining to amateur radio, including hints and kinks, your local club's activity, awards issued by other organizations, etc.

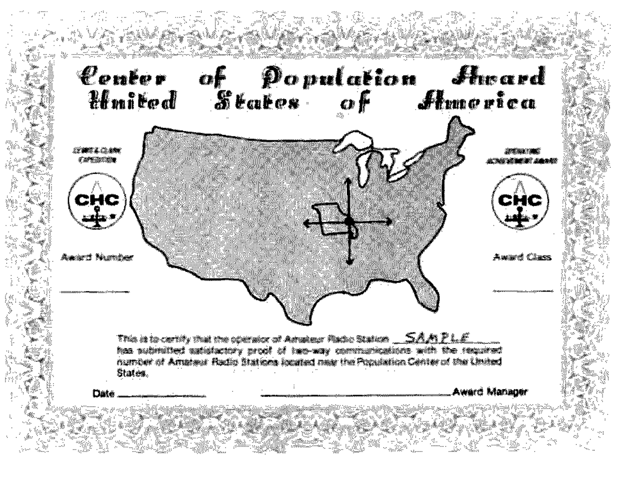
Certificates of membership are issued to each new member with the approval of their application. They are of the highest quality and are very worthy of display.

Fees/dues for the IARS, CHC, SWI-CHC, and FHC are as follows: joining each division—$6.00 (overseas—$7.00, no prorating); yearly dues, each division—$4.00 (overseas—$5.00), all due Jan. 1st.

For additional information about this complex organization, address all inquiries to: Scott Douglas KB7SB, PO Box 46032, Los Angeles CA 90046.

CENTER OF POPULATION AWARD

The geographical population center of the USA is close to St. Louis MO. To achieve this award, work one station in each state which borders Missouri. Work one station in Arkansas, Illinois, Iowa, Kentucky, Kansas, Nebraska, Oklahoma, and Tennessee, plus one station in St. Louis MO. Send list showing calls and log data plus $1 to Dean Cowden KK0V, 2317 Lee St., Poplar Bluff MO 63901.



USA AWARDS PROGRAM

There is no limit to the frequency this award is issued an applicant. An applicant can work any band or mode of operation. Endorsements are $1.00 each. Application for this awards program should be made to Scott Douglas KB7SB, PO Box 46032, Los Angeles CA 90046.

The Worked All United States Award is issued in four classes. Class AA is for DX stations only and requires the applicant to work all 50 US states. Class A1 is for domestic stations and they, too, must work all 50 states for this class of award. Class A2 requires 40 states be worked while class A3 requires 30 states be worked and confirmed.

There is a Double Worked All States Award and the only requirement here is that you work two separate stations in the required number of states for the class of award you are attempting to pursue.

Likewise, there is a Triple Worked All States Award for which you must work a minimum of three separate stations in each of the required US states.

While you are at it, consider the Worked US States and State Capitals Award. Here, points are accumulated for each state and capital city worked. A single point is earned for each. To qualify for class A (DX only), 100 points must be earned. Class B requires 80 points, while class D requires 60 points.

To add insult to injury, included in the USA Awards Program is the Worked All States, Capitals, and Counties Award. Here again, the award is based on a point system. Each state is worth one point, two points are earned for each state capital city worked, and a total of ten points is earned for working all counties in a single state. Should you accumulate 600 county points, a trophy will be awarded. The class AA award is given for 600 points, class A for 500 points, class B for 400 points, class C for 300 points, class D for 200 points, class E for 100 points, and class F for 75 points.

ALL ALASKA COUNTIES

The Moose Horn Amateur Radio Club of Penai Peninsula, Alaska, announces the availability of their award for the State of Alaska. The award, in the form of a certificate, is available to licensed amateurs worldwide.

Certificates will be issued with endorsements for special modes or bands such as: class 1 (CW), class 2 (AM), class 3 (SSB), class 4 (RTTY), class 5 (mixed mode), and suffixes A (one band) and B (mixed bands). For example, certification or endorsement for an award on 20-meter SSB would be class 3A.

To qualify for this award, applicants must make four contacts in Alaska, one for each of the four judicial districts of Alaska. Of these, one contact must be made with a member of the Moose Horn Amateur Radio Club. All contacts must be made on or after August 15, 1961. It should be noted that the present system of judicial districts will be used in lieu of counties until such time that the State of Alaska adopts a system of actual counties.

To apply for the AACA, provide a list of confirmed contacts, certified by either two amateur operators, a local radio club official, or a notary public. Forward the verified list along with one US dollar or three (3) IRCs to cover air mail return of your award. All applications should be addressed to Ken Smith KL7JFY, PO Box 1682, Soldotna AK 99669.

By the way, here is a list of the

members of the Moose Horn ARC: KL7EJM, EK, EKN, EKO, FG, GIC, GJY, GNP, HHF, HQK, IEL, IFX, IN, ISO, ISP, IQQ, IQP, IZH, JDR, JFY, JL, KJ, LB, LE, NH, AL7BU, WL7ACQ, AEG, AJF, WB9NES, and VE6NH/KL7.

USS LING

On May 8, 1982, the weekend before Armed Forces Day, so as to not conflict with the operations of the Armed Forces activities, the Meadowlands Amateur Radio Association will be on board the *USS Ling* (SS297), docked on the Hackensack River in Hackensack, New Jersey, and will be operating under club station call N2BMN. The operation will begin on Saturday, May 8, at 1500Z and end at 2100Z. The following frequencies will be operated throughout the day, alternative between CW, SSB, and FM:

MODE	FREQ.	BAND
CW	14.060	20m
SSB	14.310	20m
CW	7.115	40m
CW	7.060	40m
SSB	7.250	40m
CW	28.110	10m
CW	28.060	10m
SSB	28.650	10m
CW	144.100	2m
SSB	144.150	2m
FM	146.150	2m
FM	146.550	2m

For confirmation of QSO, please send a large SASE (8½" x 11") to Ralph Francavilla N2BMN, 154 Redneck Avenue, Little Ferry NJ 07643.

NETHERLANDS-AMERICAN BICENTENNIAL

The Holland (MI) Amateur Radio Club will operate K8DAA plus other participating stations for the Netherlands-American Bicentennial during Tulip Time, May 12 through May 16, 1982. Operations will be in all phone bands and possibly some CW. One contact with K8DAA (club station) or two participating stations qualifies for a certificate. QSL to: HARC, PO Box 92, Zeeland MI 49464.

ARMED FORCES DAY

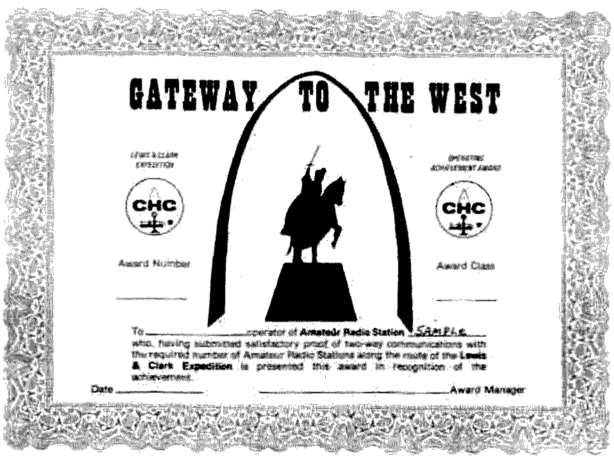
This year's observance of Armed Forces Day will include the operation of an amateur radio station from the United States Air Force Museum at Wright-Patterson Air Force Base, near Dayton, Ohio. Operating under the callsign K8DMZ, the station will be on the air from 1400Z to 2200Z on Saturday, May 15th. Operators will work primarily in the General class phone segments of 75, 40, 15, and 10 meters with periodic CW excursions to the Novice subbands. FM and SSB operations on 2 meters also are planned. The specific frequencies to be used will depend upon existing band conditions. To commemorate the event, the Museum will issue a special certificate for each two-way contact. This will be the first time an amateur radio has operated from the Museum in conjunction with a special event.

First established in 1923, the United States Air Force Museum is the oldest and largest military aviation museum in the world. It is located six miles northeast of Dayton at historic Wright-Patterson Air Force Base and is close to the Huffman Prairie site where the Wright Brothers conducted many experimental flights following their first successful powered flight at Kitty Hawk, North Carolina.

For further information, contact: Mr. Joe Ventolo, USAF Museum, Wright-Patterson AFB, Ohio 45433, (513)-255-3284, or the Museum's Public Affairs Officers, Dick Baughman or Linda Smith.

GATEWAY TO THE WEST ACHIEVEMENT AWARD

Work stations in states through which the Lewis and Clark expedition passed. Work one station in each of the following states: Idaho, Kansas, Montana, Nebraska, North Dakota, Oregon, South Dakota, and Washington, plus one station in St. Louis MO. Send list showing calls and log data plus $1 to Dean Cowden KK0V, 2317 Lee St., Poplar Bluff MO 63901.



CAPE HATTERAS LIGHTHOUSE I

The weekend of May 15 and 16, the Rockingham County ARC will be operating from the Cape Hatteras Lighthouse on the outer banks of North Carolina. This lighthouse, which at 208 feet is the tallest brick lighthouse in the country, is designated as a national historic landmark and is seen by over a million visitors each year. But this beautiful sentinel is in danger of falling victim to the Atlantic's turbulent forces. Once 1500 feet from the shoreline, it now stands less than 70 feet from the water—despite various efforts to control the erosion.

The RCARC hopes its mini-expedition will help to draw national attention to this graceful and historic landmark. Operating frequencies will be 30 kHz up from the bottom of the General portion in each band, both phone and CW.

CAPE HATTERAS LIGHTHOUSE II

When the Cape Hatteras Lighthouse was completed in 1870, it was 1500 feet from the shoreline. Today, it is 70 feet—and closing. The Cary Amateur Radio Club, Cary, North Carolina, will draw world attention to the peril of this keeper of the "graveyard of the Atlantic." On May 29-30, whether the lighthouse is still standing or not, Cary ARC members and friends will put two HF stations on the air from a site close to "the big candle." The targeted time for operation is 9:00 am (1300Z), Saturday, May 29, to noon (1600Z), Sunday, May 30, 1982. Operation may start sooner and last longer, depending on conditions and people power.

Planned frequencies for operation are: CW-3552, 7052, 14052, 21052, and 28052 kHz; SSB-3988, 7288, 14288, 21388, and 28588 kHz. The callsign will be NB4L (New Blood for Lighthouse).

Every station making a contact with NB4L during the special event can receive a commemorative 8.5" x 11" certificate by sending an appropriate SASE (1 oz., folded or unfolded) with QSL card containing the correct log information to Chuck Davis NB4I, 304 Atchison St., Garner NC 27529.

There is a public effort to raise funds to save the Cape Hatteras Lighthouse from the onslaught of the Atlantic. While many of the Cary ARC members may favor that project, this special event is only meant to focus attention on the peril of the Lighthouse. There is no connection with any fund raising.

SECOND ANNUAL COMMEMORATION OF MT. ST. HELENS ERUPTION

W7AQ, the Yakima Amateur Radio Club, will operate a special event station in commemoration of the second anniversary of the eruption of Mt. St. Helens in Washington State.

On May 18, 1980, at approximately 8:32 am local time, Mount St. Helens, located in southwestern Washington State, erupted violently. The 9677-foot summit was reduced to 8364 feet. A crater 2100 feet in depth was produced. Over one cubic mile of matter was thrown into the atmosphere.

Yakima, Washington, is located 80 miles northeast of the volcano. W7AQ was starting its hamfest activities that morning. By 10:30 am, the sky became as black as midnight. The light of the sun would not be visible until the next day.

Over 600,000 tons of volcanic dust and ash, which covered the city of 50,000 up to one inch in depth, was removed by cleanup over the next several weeks.

Join us in commemoration from May 16 at 1800 to 0200 of May 17 UTC. Frequencies will be 25 kHz up from the bottom of the General phone edge, ± QRM and band conditions. CW will be up 25 kHz from the Novice band

edge, ± QRM and band conditions and at 14.050 ± QRM and band conditions. A QSL will be available for an SASE. Send QSLs to: W7AQ, Yakima ARC, PO Box 9211, Yakima WA 98909.

MEMPHIS TN

The Memphis (TN) Radio relay Club will operate on May 22 and 23, 1982, for a weekend of the sixth Memphis in May Festival. Frequencies: CW—7,125 kHz ± QRM and 14,180 kHz ± QRM; SSB—7,280 kHz, 14,305 kHz, 21,400 kHz, 28,650 kHz, and 146.52 MHz ± QRM. Operating hours: 1400-2000 UTC, May 22, and 1200-1800 UTC, May 23, 1982. Special certificates will be issued for confirmed contact and large 9" x 12" SASE sent to N4ERU or N4CWS, 2071 Victoria, Memphis TN 38116.

PORT JERVIS, NEW YORK

The Orange County ARC will operate WB2TSA to celebrate the tenth anniversary of the club and the diamond jubilee of the city of Port Jervis, New York, on May 29 from 1400-2200 UTC and May 30 from 1400-2000 UTC. Frequencies 10 kHz up from lower general phone bands. QSL for SASE to OCARC, PO Box 434, Cornwall-on-Hudson, New York 12520.

DOGWOOD FESTIVAL QSO PARTY

The annual Dogwood Festival celebrated in Fairfield, Connecticut, will also be observed on the air by members of the Greater Fairfield Amateur Radio Association with its Dogwood Festival QSO Party on Saturday, May 8th. Members of the club will operate on six amateur bands with the club call WB1CQO and explain the significance of the festival, which marks the blossoming of the 30,000 pink and white dogwood trees in the town of 55,000 persons. Fairfield's Dogwood Festival began in 1936, although the original trees were imported from Japan in 1895 and earlier. Thousands of visitors flock to see the pink and white blossoms in full bloom during May.

WB1CQO will be on the air May 8 from 1300-2200 UTC (9:00 am to 6:00 pm) EDST. A special commemorative QSL card will be available to confirm each QSO.

Dogwood Festival stations will operate on these SSB frequencies: 3.975, 7.235, 14.330, 21.420 and 28.710 MHz. FM operation: 146.55 simplex.

Special QSLs will be sent upon receipt of an SASE or IRCs to QSL manager Grace von Stein KA1JT, 248 Euclid Avenue, Fairfield CT 06432, USA.

BISHOP MULE DAYS

The Bishop (CA) Amateur Radio Club will operate KA6AMT from the mule capital of the world, Bishop, California, on May 31st in recognition of the annual Bishop Mule Days celebration.

Frequencies: Phone—3.905, 7.240, 14.295, and 146.34/94. Certificate for a large SASE sent to Bishop Amateur Radio Club, PO Box 1024, Bishop CA 93514.

TIMBUCTOO

A special event station will be operated by the Yuba-Sutter Amateur Radio Club from the historic gold rush town of Timbuctoo, located in the mother lode country of California's Sierra Nevadas. Listen for callsign N6DDP from 1700Z May 15, 1982, to 0100Z, May 16. For a commemorative QSL, send an SASE to Y-S ARC, PO Box 1169, Yuba City CA 95992. Frequencies: 28.620-.630, phone; 21.150-.160, CW; 14.310-.320, phone.

MOSCOW OLYMPICS

The Moscow, Tennessee summer "Olympics" will be held in Moscow on May 14, 15, and 16, 1982. Communications for this annual event will be provided by the Mid-South VHF Club of Memphis. A special events station, KU4K, will be operating SSB from the site on 28.8, 14.28, and 7.2 MHz. There will be an OSCAR station in operation as well. Amateurs contacting KU4K are invited to QSL via Box 88, Moscow TN 38057. The summer Olympics is a benefit educational fund for the children of the men who lost their lives in the aborted Iranian hostage rescue attempt. Last year over $30,000 was raised for the benefit of approximately 17 children.

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 8

against the speed of the brain and are stopped.

Once this limitation was understood, it made sense to stop trying to learn code with the old system. Articles were written about it and new code courses devised to get around that old slow method and the resulting plateau. I tried to get the ARRL to recognize the futility of their old system but got nowhere. Hams had always learned code that way and they were not going to change.

After giving up on the ARRL trying to help hams learn the code, I sat down and made up my own code tapes, using the new, much faster and easier, learning system. I brought these out on cassettes as the *73* Blitz Code Course. I soon was getting letters from thousands of new hams thanking me for breaking the situation for them. Many had tried and tried the ARRL tapes and had thought they were never going to learn the code. Now they found that within a few hours they were on top of it.

My "Genesis" cassette starts off the beginner with the simplest of code characters, starting with E, I, S, and H. Then, instead of going on to the rest of the 26 letters, I immediately start sending simple words. These characters are each sent at 13 wpm speed, right from the start, thus reinforcing the sound of the character. The letters are spaced for five wpm copying.

The quick change to sending words gets the student used to success. Simple messages are being copied within minutes of starting to learn the code. This is a tremendous psychological boost.

The first one-hour tape teaches all of the letters, numbers, and punctuation marks, complete with some cute messages to make the learning experience fun. Many people are thus able to master all of the needed characters within a couple of hours of work with this tape.

The next step is my "Stickler" tape. . .again with all characters sent at 13 wpm speed, but spaced for six wpm throughout. By standardizing on 13 wpm sound patterns, the groundwork is laid for passing the 13 wpm exam. The "Stickler" is all five-character code groups and has been designed by me to be as frustrating as possible. By the time you are able to copy this code tape 100%, you should be able to breeze through any FCC exam for 5 wpm, half drunk and in your sleep. Many hams tell me that by the time they can handle this nasty tape they can copy 13 wpm of clear text with no problems.

I want to be sure that my students are overtrained. The test, particularly if it is in front of an FCC examiner, can throw even a normal person into panic. Well, there is nothing which calms the nerves as much as sitting down to do a code test and having the code sound like it is coming at two wpm. It's all in the psychology.

For the next test, I have the most miserable tape you've ever heard. The "Back Breaker," at 14 wpm, will drive you right up the wall. You won't believe what a bastard I am until you try my "Back Breaker" tape and suffer. Heh, heh. But again, when you sit down for 13 per in plain text you will not believe how slow it sounds. Many students start laughing when they hear it, losing all their tensions.

Every now and then someone writes in asking for a copy of the code groups on my cassettes. I flatly refuse to send them a copy. The reason is simple. . .I don't want them using the tapes to test code-copying speed. The system is to use the tapes, picking out the characters you recognize. You keep working at this until you automatically copy all of them. You'll know full well

when you miss one, so you don't need a cheat sheet to check. I want you to practice without the pressure to perform. Such pressures take all the fun out of code. Learning the code should be and can be fun. The more you can do to make it fun, the faster you are going to learn it. The more pressure you put on yourself, the longer it is going to take and the more unpleasant it is going to be.

The fact is that a skill with the code is a lot of fun to have. I'm hoping that we can eliminate the pressures entirely by getting the code test out of the ham license requirements, replacing it with a technical exam which means something. Then I think we will have a lot more hams developing their code ability... and enjoying it.

For the Extra class license, I have a 21 wpm cassette. Once you can handle this one you will be able to copy plain language at almost 30 wpm.

From a practical point of view there is little difference in learning the code at 13 wpm, 20 wpm, or even 50 wpm. The process is about the same and the length of time it takes to master any of these speeds is about the same. We have had some interesting experiments with starting newcomers right out at 50 wpm... and succeeding!

The *73* code courses are available from us by mail order. They are also stocked by most ham stores. These stores are still selling the ARRL course...the one which I feel has lost us several hundred thousand hams. Many clubs are still taking hour after hour, struggling with the 1930s code system from the League. Modern ideas sure are difficult to get across.

FIGHTING BACK

Every now and then I get a stroke of inspiration. The other day, while I was sitting in the lounge of a restaurant waiting for my name to be called to get a table, a chap next to me started smoking a cigar. Being, as you may know, a non-smoker, I had immediate need of a gas mask. Cigarettes are annoying, but a cigar or pipe is just too much. I got up and went to another restaurant.

There must be some way to fight back. There really has to be a way. That was the train of thought that brought on one of my all too few strokes of semi-genius. If these turkeys can stink up the air I have to breathe, what's wrong with me stinking right back at them? How about an aerosol can of stink?

The first thought was to see about getting some cans of methane. Then I could sort of spray it and pretend that I fired back with a built-in weapon. But, alas, that might get ignited by the cigar or pipe and blow both of us to smithereens. No, the stink should be as offensive, but not be explosive. Perhaps skunk juice or hydrogen sulphide (rotten eggs). Yes, that would do it.

Put out in small pocket- (purse-) sized cans, I think it would sell. We might call it FIGHT BACK. It would be the first way for non-smokers to even the score. At $1 a can, it should sell well, Hmm, I'll have to look into this.

FOREIGN AID

One of the great benefits of amateur radio is that it allows us to sit and talk at length with hams in foreign countries. Unfortunately, few of us take the time to try to get to know amateurs in other countries, which is both our loss and theirs. Most of us are so swept up with contests and working countries that we say to hell with the chap at the other end.

I remember when I first moved to New Hampshire and went on the air. I found myself being called quite often by hams "needing New Hampshire." This quickly got to me. These chaps had no interest in me or in New Hampshire. All they were interested in was a QSL card. Now what is the possible value of a card from someone you didn't even bother to do more than casually bump into on the band? Hams needing New Hampshire seem to go out of their way not to get involved with any real conversation. They are almost always uninterested in paying any dues for the card in the way of an interesting contact. The QSL card is supposed to be the final courtesy. In this case, it is often the *only* courtesy involved.

Amateurs in all foreign countries run into this syndrome. In the rare ones, they seldom run into much else. If they get fed up with non-contacts with hams in search of their pasteboards and start making contacts by calling some of the stronger stations... or hams they know.. the hunters make their lives miserable with break-ins, tail-endings, and the like. If ignored, these QSL hunters can get vicious. This can diminish the fun of amateur radio substantially.

There probably isn't much that can be done about this whole lousy situation as long as the fascination continues for being high on the ARRL Honor Roll. Can I call it a dishonor roll?

At any rate, if you should want to fight the self-destructive urges to treat DX operators as mere QSL factories for your collection...providing you with an ever higher listing on an occasionally printed list in an obscure magazine and not much else to show for a lifetime of DXing...then perhaps you can join me in finding out that many DX hams are highly interesting people. I can tell you this: Once you start talking with them, you are sure to become addicted to it.

You know that in a country where there are from one to ten hams you are not likely to be talking with a blue-collar worker. It is highly likely that you will be talking with a relatively important or wealthy person. He is also likely to be particularly interesting, if you can get him to talk.

One of the conversational openers which I've found to work has to do with asking about their country. From there, I just sit back and listen. You know, it wouldn't hurt you to invest in one of the almanacs and read up on some of the smaller third-world countries so that you'll have some questions to ask which show more than a casual interest.

One of the subjects which may interest you has to do with aid funds the country is probably getting from ours. This can bring about an interesting conversation in some cases...and embarrassed silence in others. I have the advantage of getting around to visit hams in many of the third-world countries, so I ask about foreign aid when I visit them...and find many open to give vent to their feelings about this.

Since this is where I was heading when I started, it isn't exactly a digression. This business of foreign aid has been bugging me for a long time. The way the situation is set up right now, this money is wasted for the most part. It doesn't have to be.

As I wrote recently, the heads of a great many of the third-world nations are kept in position by virtue of the money they are able to grab for their supporters. Even the poorest of countries can be bled further by these pirates. But they are expert at working on the sympathies of the wealthier nations to get aid funds. The US is a particularly good sucker for this. Rarely does even 10% of this "aid" money accrue to the benefit of the poor people of the countries.

Presuming that Uncle Sap is going to continue to try to buy friendship (a commodity which seemingly can't be bought) with handouts, we could at least send aid which would be more difficult to turn into cash and at the same time provide some feedback of the money to US industries. My proposal is for future aid to take the form of goods, not cash, and that this should be goods from small business manufacturers rather than the big corporations. That would keep most of the lobbyists out of the pork barrel.

When we send cash, the most desired commodity, to these countries, most of it ends up in Switzerland without even coming near the people for whom it was intended.

Getting back to amateur radio, as you talk with the DX amateurs I think you'll find them enthusiastic for you to visit them. And I've found that a surprisingly high percentage of these amateurs manage to get to the US now and then. See if you can get them to include a day or two visiting you. Then you'll be able to find out a lot of things which they really couldn't talk about over the air.

Remember that 97.1e has to do with your ability to contribute to international goodwill. Pileups and tail-ending are not likely to do this. Presenting the friendly face of America to the world will. It's up to you whether we look like ugly Americans or not.

LETTERS

"CRACK THE WHIP"

First of all, I do *enjoy your* magazine and respect your right to an opinion on various topics (although sometimes I disagree), but on this business of a code-free license, I must make an objection.

I don't understand how Japan can have so many more amateurs than the US when the current *Callbooks* don't support this statement. But regardless, I will accept your word as you are in a better position than I am to know.

In my opinion, the reason why the US is declining in new engineers and high technology is because the youth of America is not made of the same fabric as that of our oriental brothers. At age 30, I *am* currently enrolled in an electronics program at a local community college and it is my impression that most of the "fresh-out-of-high-school" crowd are there merely because of parental pressure to get a degree. This school has one of the most thorough and modern electronics programs in the state and can compete equally with any big university on the educational level.

But the fact still remains that most of the younger students are "just going for a degree" and could really care less about the field they are pursuing. Possibly at one time they happened to open up a transistor radio, marveled at how it could do what it does, and *decided* this would be a less boring field than, let's say, social science or psychology.

The Japanese seem always to do things a little better, kind of a oneupsmanship, if you will, than their counterparts of the west. It is because they want to, Wayne . . .not because someone is standing over them with a whip!

If there is a minute problem with lids in Japan, what with their code-free licensing, that doesn't necessarily mean the same will hold true here.

You have stated that our technology could be much improved by technicians and engineers that were "sparked on" by being exposed to amateur radio during their youth. Well, if this is the case, then why didn't this happen with the Citizens Band service of the past? You couldn't have an easier way to get a ticket and get on the air than just to send off to the FCC for an instant license. Granted, a lot of superior hams graduated from the CB ranks and a lot of them probably went on to become technicians and engineers, but you know as well as I that the overwhelming majority did not. And look what the CB service is now without the *discipline*! Notice the emphasis on the word discipline? Learning code is a matter of discipline, period! There is no other word for it; that is it, in black and white. The Japanese are disciplined. As a matter of fact, they are noted for it. Maybe that is why they can handle a code-free licensing program without any problems.

How would you compare American youth to Japanese youth? Is one better than the other? No, but one is more disciplined. In WWII, we destroyed Japan and rebuilt it and, as a consequence, they became more disciplined. Given that fact, who do you think would be more arrogant? We have enough arrogance on the bands already. Let's try to get more discipline on the bands and not open up the floodgates for more arrogance. I don't think your theory holds too much water, Wayne. I teach new Novices and they *can* learn the code and *enjoy* doing so. It's just a matter of presentation and a little discipline.

It's been a while since this country has led the industry and I'm afraid it will be a lot longer until we can change the attitude of the people, especially that of the youth. Besides, if the overwhelming majority of hams today don't prefer a code-free license, why fight it? This *is* supposed to be our service, isn't it? We should have some say about how we want it! There will always be enough people to keep us a viable commodity on the FCC "exchange." And those are the ones we want. *Disciplined!*

Dave Peckham KD9D
Decatur IL

Dave, such a bunch of questions! Good ones, though, so let me tackle them one at a time. First, regarding the Callbook. *If they listed only the Extra class US hams, the US* Callbook *would be small, too. The Japanese* Callbook *is huge because they list all classes of licensees . . .over half a million of them. Now, about American kids and technology. . .the magic happens in the teen years. In the past, about 75% of the new hams were teenagers, with the old ARRL polls showing 50% being either 14 or 15 years old. There is now and there always has been an enormous difference between the type of engineer we get from dedicated teenage hams and from people who decide to just go for a degree. That's the same now as it always was and the chap who goes for a degree is usually a grave disappointment by comparison. Boy, I've known a lot of 'em.*

Now about CB. Dave, think about it. . .the mess is awful, with piles of interference, contacts which are even more boring than most ham contacts (yes, I know that's hard to believe), bodacious signals, and so on. . .how do you honestly expect anything good to come from such an incubator? The few CBers who managed to be salvaged by friendly hams are a blessing to us and to CB, but they are few, with most of those exposed to CB recoiling from the gore. No, there is a world of difference between an interference-hassled contact on one of the CB channels and a half-hour rag chew with someone in Germany or Australia, so please don't try to equate the two in your mind.

The Japanese aren't any better than we are. They just went the right way when we went the wrong with that foolish attempt to return to prewar Class A and B licensing in 1963. We now know how to fill our bands with crazies. . .use a code test and let Bash do away with the technical requirements with his books and blitz one-day memorization bashes. If you want garbage, you know how to get it. And Dave, remember that in 1969 the overwhelming percentage of the hams hated two-meter FM and didn't want to read about it or hear about it. Every now and then amateur radio needs someone to provide some leadership. I've found that in the long run people (even hams) will think things through and eventually get away from slogan thinking and work for what is in the long-range interest of amateur radio. We really couldn't ask for more proof that the code is a total failure as far as keeping out the nitwits (my apologies to any nitwits reading this and taking offense. . .which is an unlikely prospect) out of the hobby. Now that we have a way to easily cheat on the technical test, all we need is a way to cheat on the code and you have what you asked for: open sesame. I want to throw out the proven loser, code, and substitute a meaningful technical entry exam. . .one that can't be bashed.

If we get our spirit up, we can beat the hell out of any country in the world. . .including Japan. We can out-invent them, out-produce them, and out-quality them . . .if we decide that it is important to us. I want to get this started by getting kids infected with the ham bug when it is the easiest to pass along this infection: in high school. Dave, if we can get even half of the ham clubs to get some enthusiasm for selling amateur radio. . . classes. . .monitoring systems to keep our bands clean. . .emergency cadres so we will be ready to provide quick service for any kind of emergency. . .pressures on our high schools to start and support ham clubs. . .we'll be able to change the world in ten years. Or we can sulk and let amateur radio rot away the way it has for the last few years. Your choice. — Wayne.

CATCHING THE DREAM

Wayne, your editorials always ring my bell. You have the best interests of amateur radio at heart — we know that. I admire your business acumen; you are a true pioneer. I met you a couple of times at Dayton and enjoyed your magnetic and energetic personality.

Yet, agreement we don't have. You constantly compare American and Japanese amateurs to our disadvantage. Each has different goals and attitudes. The civilizations are vastly different. Japan may have no code requirement for entering amateur radio, but many Japanese amateurs are competent CW operators. I just don't believe our declining ranks results from the code requirement.

With that out of the way, what makes a prospective American

radio amateur stick with it, become a ham, and advance in rank? It's not the presence or absence of a requirement. It's the degree of personal drive inherent in the individual as well as how he latches onto the opportunities that come his way. As I see it, Wayne, if he is interested, he will keep at it until he makes the grade.

If Johnnie is let off from learning how to read, Johnnie is going to be let off from mathematics and a lot of other school requirements. From what I have seen of the Japanese civilization, Hiko and Toshio are not passed for non-achievement in school. Japanese education is strict and no-nonsense.

I learned Morse code in the Boy Scouts; my high school supported an excellent radio club. While a senior, I was permitted an operating hour daily in the club station as long as my grades were up. True, I had advantages, but I made use of them and passed my exams fair and square fifty years ago. Passed my Extra class thirty years ago.

Continue to agitate against the code requirement, Wayne, but I don't think it will stop the young in heart who have really caught the dream.

Paul L. Schmidt W9HD
Bloomfield IN

Paul, I agree with you. I don't think the code has much to do with our declining ranks. I think that if we can get the kids exposed to amateur radio rather than CB...or drugs...we'll get into clining ranks. The code is a loser as far as separating the wheat from the chaff. We need to get back to having this a technical hobby. If we insist on hams having an understanding of radio instead of merely having to pass a stupid code-skill test, a test which has flooded us with dregs from the pits...we might be able to look for some progress and have more pride in our hobby and hams. The cretins who are screwing up amateur radio are naturally repelled by 73, so I can write freely about them. You are right about education, too...there is much to be said for some of the no-nonsense Japanese approach as opposed to the Dr. Spock permissiveness which we have fallen into over the last twenty years. Every psychological survey shows that kids respond better to much stricter guidelines...and are happier. But that would force the average parent to look up from the television set now and then...so forget it. No, if we're going to get kids out of the mess they're in, we're going to have to trap them with the fun of amateur radio...the fun of talking with the world...the fun of building...the fun of learning ...of experimenting...of doing things few others can do. I feel this is a tremendous resource and should be used to change our country and give it back some pride. — Wayne.

CALL FOR PAPERS

Papers are invited for the 1982 Annual VHF Conference to be sponsored on October 23, 1982, by the Electrical Engineering department, Western Michigan University. Principal emphasis will be placed on engineering developments applied to radio communication, design, and construction on the frequencies of 30 to 1200 MHz. Papers on a wide range of subjects are solicited including, but not necessarily limited to, these:

- Antennas and transmission lines
- Applications of microprocessors
- Audio-frequency equipment used with VHF transmitters and receivers
- Emergency gear
- Grounding and shielding
- Keying, break-in, and control circuits
- Measurements and test equipment for VHF
- Mobile and portable equipment
- Modulation and mixing
- Narrowband voice modulation
- Noise reduction
- Phase-locked loop uses
- Picture transmission and reception
- Power supplies including switchers
- Production technology and model building
- Propagation
- Recent equipment/new apparatus
- RTTY
- Satellite and Moonbounce topics
- State-of-the-art semiconductors, ICs, and filters with applications
- Transceivers

One of the basic purposes of this Conference is to provide a maximum opportunity to present findings by those experimenting, designing, constructing, testing, and inquiring into problems and methods applicable to VHF radio. This is an opportunity for beginning or mature researchers to report their findings to their peers. We especially encourage the inexperienced inquirers to obtain some experience by presenting a paper at our VHF Conference.

Authors wishing to present papers should send a synopsis or abstract (typically one or two pages with diagrams) describing the paper to Dr. Glade Wilcox W9UHF, Chairman, VHF Conference, Department of Electrical Engineering, Western Michigan University, Kalamazoo MI 49008. Foreign authors are requested to have a US contact.

Deadline for submission of synopses is June 30, 1982. Speakers will be notified of acceptance by July 4, 1982. Reproducible copy for the printed proceedings should be mailed to the Chairman two weeks prior to the day of the Conference.

Glade Wilcox W9UHF
Kalamazoo MI

ELMER LIVES

After reading the November, 1981, issue, and noting the letters to the editor from Frank D. Windsor and Tom Taorimina, I felt that I could no longer be silent. I am an aspiring Novice who hopefully will have upgraded to General by the time you receive this.

I became interested in ham radio as a youngster, but did not have the time necessary to devote due to college, medical school, residency, and then early struggling years of practice. In November, 1981, I learned the code and began to study theory. I immediately ran into problems, and needed to discuss my problems with someone more knowledgeable than myself. One of my patients (N9ATB) overheard my predicament and offered his services. Within two weeks, he had guided me past all of the rough spots; frequently he allowed me to listen and observe at his home while he made QSOs. He administered my Novice examination for me in early January.

As I progressed and started to increase my code speed, several other hams became known to me. I also discovered that another physician in my community was a ham. KB9DD has spent many hours working with me and has even made practice QSO tapes for me so that I could become more proficient at code and be really ready for the General exam. His assistance has been invaluable to me.

Through people like this I have come to truly appreciate the amateur radio spirit. I am no babe-in-the-woods: I have heard the foul language on 20 and am aware of the other problems that Frank and Tom illustrate, but I am certainly not convinced that things are as bad as they say. Elmer is sure alive and well here. All of the hams I know are courteous, helpful, and represent their hobby as true gentlemen. It is my privilege to join their ranks. I only hope that someday I can provide as much help and encouragement to a potential licensee.

Gregory L. Darrow, M.D.
Janesville WI

CHEAP-SCAN!

I read your article by Jeff DeTray WB8BTH regarding memory scan for the TR-9000. I am the owner of one myself and, like Jeff, realized to top off a great rig surely Kenwood could have had a memory scan. Well, here's the bottom line: the TR-9000 does have a memory scan; they just haven't brought the function out to a control! I sympathize with Jeff. His memory scan cost him $39.95; mine cost the price of one silicon diode, two pieces of wire, and some thinking.

The TR-9000 is microprocessor-controlled. (At this point, get your TR-9000 manual out.) Find the circuit diagram of board X53-11G0-11. (If you don't have a manual, rip the lid off your rig and remove the front control section by removing 4 screws, 2 on each side — allowing the front section to be moved to see and work on the board behind it.) Note Q15, the microprocessor; now all you have to do is connect pin 13 (PE-1) through a silicon diode to pin 38 (PB-1). Obviously, you won't want the scanner running continually, so a switch is needed. As some of the switches on the TR-9000 are DPDT and only used as SPST, I used the unused side of the NB switch.

Trace PE-1 + PB-1 on the board 'til a suitable pick-off point is found. Then remove the front panel, remove the power/volume control, and you will see

on the circuit board where one side of the NB switch is not used.

The result is that when NB is out, the scanner is in and can be controlled by scan and hold buttons manually. And when a signal is present, it will stop until it ceases, and then continue. If mike P/T is operated, the scanner will stop and has to be restarted manually by pushing SCAN on your rig.

A simple addition to a fine rig.

Tasmania, Australia

FAR SCHOLARSHIPS

The Foundation for Amateur Radio, Inc. (FAR), a nonprofit organization with headquarters in Washington DC, plans to award nine scholarships for the academic year 1982-1983. The Foundation, composed of fifty local area amateur radio clubs, fully funds two of these scholarships from the proceeds of the Gaithersburg (MD) Hamfest. It administers, without cost to the donors, two scholarships for the Quarter Century Wireless Association and one each for the Richard G. Chichester Memorial, the Radio Club of America, the Young Ladies' Radio League, the Edmund B. Redington Memorial, and the Amateur Radio News Service. The last-named award is new this year.

Radio amateurs holding at least an FCC General class license or equivalent may compete for one or more of these awards if they plan to pursue a full-time course of studies beyond high school and are enrolled or have been accepted for enrollment in an accredited university, college, or technical school. The scholarship awards range from $300 to $900, with preference given in some of them to residents of specific geographical areas or the pursuit of certain study programs.

Additional information and an application form can be requested by a letter or QSL/postcard postmarked prior to May 31, 1982, from me.

The Foundation is devoted exclusively to promoting the interests of amateur radio and to the scientific, literary, and educational pursuits that advance the purposes of the Amateur Radio Service.

College Park MD 20740

WOODPECKER REFORMED?

Over the past several months, the amateur bands have experienced to a varying degree deliberate interference that has acquired the label "The Woodpecker."

I have read of efforts to have this interference eliminated, by political and non-political bodies. However, all efforts in the past have not been effective. Based on the old-time adage of "if you can't lick them. . .", perhaps we could take advantage of this activity.

There are various propagation indicators and forecasts to aid amateurs in their efforts to communicate. Why cannot the Woodpecker be used in the same manner? It should certainly provide band-opening information, at least in some direction.

I wonder, if worldwide attention were given to this activity on a scheduled basis, perhaps the instigators of this noise might feel they are contributing too much to the welfare of others. When WWV and others give the solar-flux index, they could also give the "Woodpecker: forecast for various frequencies and times." I'm sure this information is being kept somewhere; let's put the Woodpecker to good use!

Glenn A. Churchill KA2IOI
Hudson Falls NY

FCC SPELLING

This is in reference to the letter from Bill Crowley on page 121 of the February, 1982, issue of *73 Magazine*.

There are no incorrectly spelled words in any of the Morse code tapes which the FCC uses to test amateur radio operators. The word "Springfield" is contained in some of the tapes, and it is spelled correctly, not with a "C" as Mr. Crowley alleges.

After the publication of Mr. Crowley's letter, the cassettes used by the Boston office were double-checked to see if the tapes had somehow been garbled or partially erased. It was found that these tapes are in good condition.

I regret that Mr. Crowley felt it necessary to encourage others to complain about a situation which does not exist. The Commission continues to make every possible effort to ensure that the amateur radio examinations are unambiguous and straightforward.

Vernon P. Wilson
Chief, Regional Services Division
FCC
Washington DC

Now we have heard the FCC's side of the story. What has been your experience? — N8RK.

A MATTER OF CHOICE

Sorry, Wayne, but Jim Owens W5FQE's letter (January, 1982) hit the nail on the head. My wife renewed last year's subscription only because she got it mixed up with *QST*.

Mitch Armstrong W7CDM
Puyallup WA

This letter was forwarded to us by QST. *— Ed.*

ATLANTA SCHOLARSHIPS

The Atlanta Radio Club announces that three (3) cash $500.00 scholarships will be awarded to graduating high-school seniors who enter an accredited college or university in the fall of 1982. Recipients must be duly licensed amateur radio operators at the time of application.

This is the fourth consecutive year in which the Atlanta Radio Club has been able to award scholarships to deserving amateurs. The three scholarships to be awarded in 1982 represent an increase of one additional scholarship over past years.

For additional information and application forms, write to Phil Latta W4GTS, Secretary, Atlanta Radio Club Scholarship Committee, 259 Weatherstone Parkway, Marietta GA 30067.

Completed applications, along with the required high-school transcript, must be postmarked not later than July 1, 1982.

Morris Johnson KB4IT
Atlanta GA

FATHER OF SSB?

Jeanne Hammond's excellent article, "The Father of FM," in the February, 1982, issue does not mention single sideband. I believe Major Armstrong was the first to use this type of radio communication, and I mentioned this in my book, *Radio Stations Common? Not This Kind*. If anyone does not agree with this record, would they please provide the source of the detail on who they believe was first with sideband? Major Armstrong had so many firsts that we now take for granted that Jeanne probably did not mention this one because she was concentrating on his accomplishments with FM.

Sambro Head NS
Canada

EYEBALL TIME

July of this year marks the 25th reunion of the VHF radio amateurs who were members of the Oklahoma Central 6-Meter Club, later known as the Oklahoma Central VHF Club. All persons who were at any time members of this group are urged to write immediately to T. W. Stevens W5VCJ, PO Box 976, Edmond OK 73083. Give him your name, address, and present call and indicate whether you are interested in attending the reunion, which will be held at the same time as but not in conjunction with the Oklahoma City "Ham Holiday."

Carl C. Drumeller W5JJ

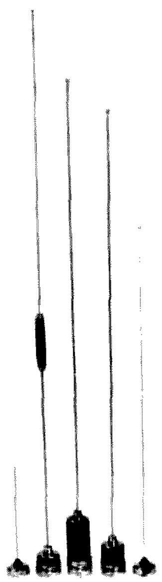
Richmond VA 23233

NEW PRODUCTS

PROFESSIONAL-AMATEUR ANTENNA SERIES

Valor Enterprises has introduced the Pro-Am (Professional-Amateur) line of antennas, mounts, and accessories that are compatible with the Motorola TAD and TAE mounts, a system used extensively by the amateur and commercial communities.

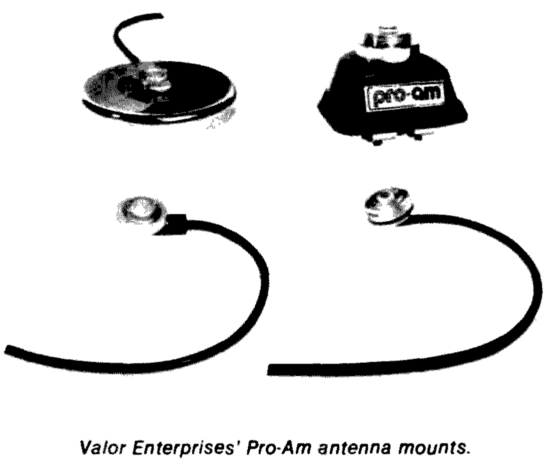
Four mounts are offered. The model PAS ($11.25) is a basic surface mount that installs in a ¾" hole (lower left in photo). Valor's model PAS38 ($11.25) basic surface mount installs in a ⅜" hole (lower right), while the model PAT ($14.85) is a no-hole trunk mount (upper right). The fourth mount, model PAM ($22.00), is a low-profile magnetic base (upper left).



Valor Enterprises' Pro-Am antennas.

The Pro-Am antennas are available in four categories. Left to right in photo: models PAQ ($5.95), of which there are twelve versions, act as ¼-wave whips for frequencies between 136 and 866 MHz; model PUB ($24.50), a 5-dB collinear series, available for 440-512 MHz; model PLB ($26.35), a ¼-wave, base-loaded antenna that can be selected to cover *any frequency* in the 27-to-54-MHz spectrum, and model PHB ($23.25), a ⅝-wave design that offers 3 dB of gain on the two-meter and 70-cm bands. (Another model PAQ is on the right.)

All models are engineered for demanding environments, featuring stainless-steel whips, nickle-chrome-brass parts, and "O"-ring seals. For more information, contact: *Valor Enterprises, 185 West Hamilton St., West Milton OH 45383.* Reader Service number 482.



Valor Enterprises' Pro-Am antenna mounts.

KENWOOD'S TS-930S HF TRANSCEIVER

Trio-Kenwood has announced the development of a top-of-the-line, all solid-state, high-frequency transceiver, the TS-930S. Designed to cover all amateur bands from 160 to 10 meters, the TS-930S also incorporates a 150-kHz-to-30-MHz general-coverage receiver which offers excellent dynamic range. Among the more interesting features to be found on this model are an automatic antenna tuner, dual digital vfos, eight memory channels, dual-mode noise blanker, i-f notch filter, fluorescent tube display, rf speech processor, rf step attenuator, and 100-kHz marker.

Kenwood's TS-930S HF transceiver.

Special circuitry allows the operator to adjust the i-f passband characteristics for rejection of interference and includes a tunable audio filter for CW reception. Power input is 250 W PEP SSB, 250 W dc on CW, 140 W dc on FSK, and 80 W dc on AM. The built-in power supply operates on 120, 220, or 240 V ac. Kenwood's newest HF transceiver will have a list price under $2000. For more details, write to *Trio-Kenwood Communications, PO Box 7065, Compton CA 90224.*

220-MHZ ALL-MODE AMPLIFIER

Mirage Communications Equipment, Inc., has announced the release of a new 220-MHz amplifier. The C106 amplifier is a solid-state, "all-mode" amplifier designed to be used in the 220-to-225-MHz amateur band. It will amplify a 10-Watt radio to more than 60 Watts output, or a 2-Watt radio to 25 Watts out. Since the C106 is biased as a linear amplifier, it can be keyed with as little as 300 milliwatts.

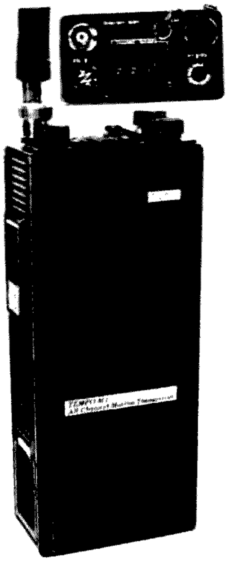
Other features include remote operation with the optional RC-1 remote head, and external or internal keying circuitry. The C106 lists for $199.95. For further information, contact *Mirage Communications Equipment, Inc., PO Box 1393, Gilroy CA 95020.* Reader Service number 490.

NO-RADIAL VERTICAL ANTENNA

Cushcraft has introduced the R3, a no-radial 10-, 15-, and 20-meter gain antenna. The R3 is perfect for limited-space applications like condominiums, apartments, mobile homes, and small urban lots. It is a ½-wavelength, endfed 22′ radiator with remote tuning for broadband coverage.

Installation is very simple, with only one square foot of space needed. It also can be telescoped for easy carrying and storage. Because of its unique design, the R3 does not need a tower, rotator, large support mast, or tuner. For more in-

Cushcraft's R3 no-radial vertical antenna.



Henry Radio's all-channel marine portable.

formation, contact *Cushcraft Corp., PO Box 4680, Manchester NH 03108.* Reader Service number 476.

ALL-CHANNEL MARINE PORTABLE

Henry Radio is introducing a marine VHF-band portable, the Tempo M1. The M1 operates on every marine channel, both US and international, with all the necessary offsets built in. It also includes all weather channels and a channel 16 override function. Channel selection is made by a thumbwheel switch on the top panel.

Other features include a one-hour, quick-charge-type battery, permanent memory, a high-power, 2½-Watt position, and a low-power, 1-Watt position. Accessories will include a charger, holster, amplifier, and high-capacity batteries.

The Tempo M1 is available through the Marine Division of Henry Radio. The suggested list price is $495.00. For more details, contact *Henry Radio, 2050 S. Bundy Dr., Los Angeles CA 90025; (215)-820-1234.* Reader Service number 480.

TELEREADER TERMINAL

The Hal Communications CWR-670 is a compact electronic communications terminal designed for reception of Baudot and ASCII radioteleprinter signals as well as Morse code signals. The CWR-670 includes built-in RTTY and Morse demodulators and video-generation circuits. The very small size of the CWR-670 makes it ideal for applications where space is limited.

The Hal CWR-670 Telereader terminal.

Since the terminal operates from 12 V dc, it may easily be used in locations where ac power is not readily available. The video-output screen of the CWR-670 is formatted in pages of 16 lines, 32 characters per line; a total of two page screens may be selected. The internal RTTY demodulator allows selection of three standard shifts. A parallel ASCII-printer output is also provided. The CWR-670 has a list price of $495.00. For more information, contact *Hal Communications, Box 365, Urbana IL 61801; (217)-367-7373.* Reader Service number 483.

REPEATER CONTROLLER

Advanced Computer Controls has introduced its new microcomputer-based RC-850 repeater controller. The controller's characteristics are remotely configured by the repeater owner with highly-secure tone commands. No hardware or software changes are required to modify control operator and user codes, ID and tail messages, Morse code speed, pitch and level, and a host of other functions.

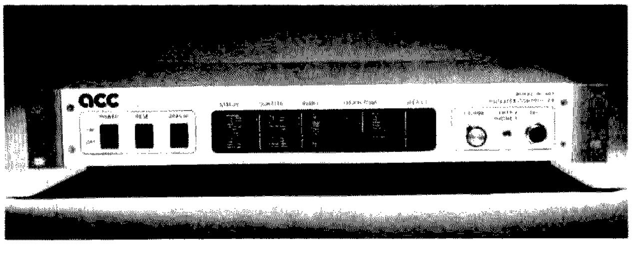
The RC-850 controller's autopatch is based on a store/forward technique where the user enters a phone number and the controller actually dials the phone using either touchtone™ or dial pulses. Logic outputs allow remote control of equipment at the repeater site. A voice-telemetry option adds a natural-sounding speech synthesizer with analog-measurement capability.

The controller uses CMOS logic and low-power, analog circuitry to minimize current consumption. The RC-850 is priced from $1850. For more information, contact *Advanced Computer Controls, 10816 Northridge Square, Cupertino CA 95014; (408)-253-8085.* Reader Service number 478.

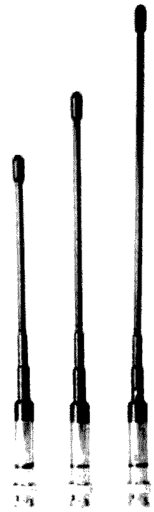
RTTY PROGRAM

The Egbert RTTY program transmits and receives RTTY without the need for any expensive interface hardware. The Apple cassette ports connect directly to the transmitter/receiver. Program capabilities include 60-, 67-, 75-, and 100-wpm Baudot and 110-baud ASCII, type-ahead buffer, canned messages, and automatic CW identification.

The program runs on the 48K Apple II and requires an Apple disk with DOS 3.2 or 3.3. The program and instruction manual cost $42.45 and are available from *W. H. Nail Co., 275 Lodgeview Dr., Oroville CA 95965.* Reader Service number 487.



The RC-850 repeater controller.



Centurion International's flexible antenna.

FLEXIBLE ANTENNA

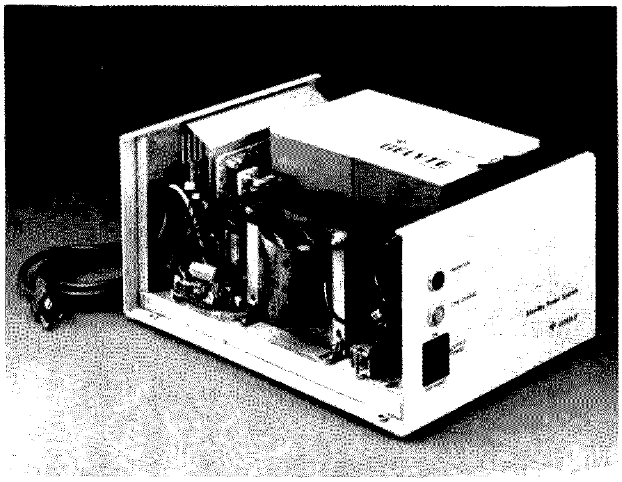
Centurion International has introduced a new flexible UHF gain antenna for use with handheld radios. The antenna features an endfed design and represents a ½-wave radiator with approximately 2.5 dB gain over a ¼-wave portable whip antenna.

The antenna is factory-tuned to discrete frequencies from 406 to 512 MHz and has a usable bandwidth of 20 MHz. The base is fitted with a BNC connector. Designated Style G, the new antenna ranges in length from 7 to 13 inches and lists for $17.50. For more information, write or call *Centurion International, PO Box 82846, Lincoln NE 68501; (402)-467-4491.* Reader Service number 484.

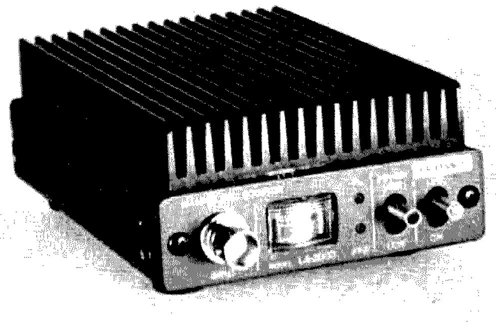
STANDBY POWER SYSTEM

The Portable Battery Division of Gould, Inc., has announced a Standby Power System (SPS) which provides 200 Watts of emergency power at 120 volts for 20 minutes, taking over the job of supplying power within one cycle of power failure.

As long as the power is constant into the SPS, the current passes through to the computer or other device being powered. However, if power drops below 102 volts, a sensing device immediately switches to an internal battery and turns on a red indicator light. If the power outage is brief, the device will automatically transfer back to line power and recharge the internal battery. Gould's standby power



The Gould standby power system.



Daiwa's booster amplifier.

system has a suggested price of $489.00. For more details, contact *Gould, Inc., Portable Battery Division, PO Box 43140, St. Paul MN 55164.* Reader Service number 486.

MORSEMATIC KEYER UPDATE

Advanced Electronic Applications, Inc., has announced the latest generation of the MorseMatic keyer, the MM-2. The MM-2 is a full-feature, paddle-input keyer that offers virtually all the features of the MM-1 predecessor plus CMOS memory and a new price. Like the MM-1, the MM-2 offers features that include an automatic serial-number generator, an automatic beacon mode, and an automatic speed-increasing Morse code trainer mode.

The MM-2 keyer comes in an rf-protecting metal package and is powered by 10 to 16 V dc. Independent + and − output keying allows connection to virtually any amateur transmitter. For further information on AEA's new $139.95 keyer, write *Advanced Electronic Applications, Inc., PO Box 2160, Lynwood WA 98036, or call (206)-775-7373.* Reader Service number 491.

COMPANDOR KIT

Advanced Analog Systems has announced a design evaluation kit for the Signetics NE572 dual-programmable compandor. The kit, designated AAS572, contains a printed circuit card, integrated circuits, and all components necessary to construct a complete audio compandor.

The system consists of two compressors and two expandors. Input to the compressor section consists of a high-performance, low-noise voltage follower. The system can be evaluated with either a single 2:1 compressor or by switching the ratio selector for 4:1 compression. There is also a choice between 1:2 and 1:4 expansion. Power requirements are plus and minus 15 V. The AAS572 costs $65.00 in single quantities. For more details, contact *Advanced Analog Systems, 790 Lucerne Dr., Sunnyvale CA 94086; (408)-730-9786.* Reader Service number 488.

BOOSTER AMPLIFIER

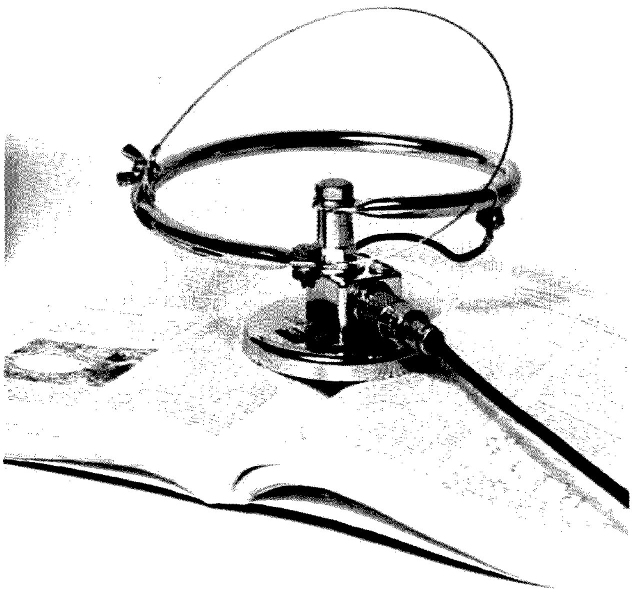
Daiwa announces a compact, lightweight amplifier, the LA2030, intended for the owners of two-meter, hand-held transceivers. It is available in three versions, depending on the power output of your transceiver. All versions can deliver a maximum of 15 or 30 Watts from 144 to 148 MHz.

The Daiwa LA2030 includes rf power metering and protection circuitry. The unit comes equipped with a BNC input and SO-239 output. Three feet of coax and BNC connectors are included in the $121.00 price. For more information, contact *MCM Communications, 858 E. Congress Park Dr., Centerville OH 45459; (513)-434-0031.* Reader Service number 481.

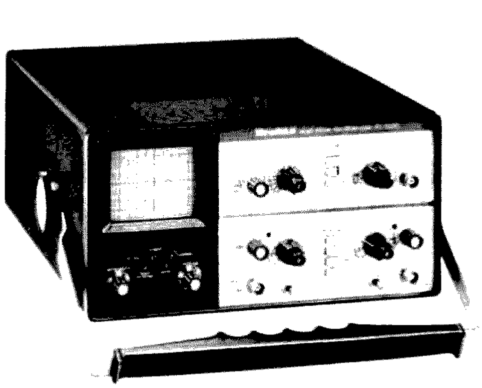
TWO-METER DDRR ANTENNA

High efficiency and small size are two key features of the Comrad Industries CR2A two-meter antenna. The CR2A is an adaptation of the Northrop Direction Discontinuity Ring Radiator (DDRR). Comrad's CR2A offers vertical polarization in a low-profile package suitable for either base or mobile use. Priced at $39.00, the CR2A is available from *Comrad Industries, 1635*

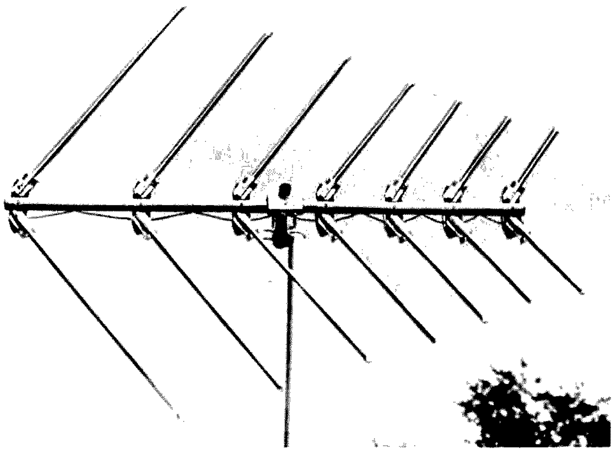
MorseMatic keyer update, the MM-2.



Comrad's two-meter DDRR antenna.



Heath's portable oscilloscope.



Low-power, wideband antenna.

West River Parkway, Grand Island NY 14072. Reader Service number 477.

SATELLITE TELEVISION RECEIVER

Arunta Engineering Company has introduced the DD 3000 stereo satellite television receiver. The DD 3000 can process multiplex, matrix, and discrete modes of stereo transmission in either wide- or narrow-deviation format.

Other significant innovations include a simplified installation requiring only an RG-59 cable between the receiver and remote downconverter, which transmits i-f, LNA power, and tuning voltage. With a suggested list price of $2995, the DD 3000 is available from *Arunta Engineering Co., PO Box 15082, Phoenix AZ 85060; (602)-956-7042.* Reader Service number 479.

PORTABLE OSCILLOSCOPE

Heath Company is introducing its first portable oscilloscope. The IO-3220 20-MHz oscilloscope can be used for most electronic measurement and comparison needs. It offers dual-trace capability, X-Y inputs, and a special algebraic add function. The IO-3220's sensitivity allows it to measure vertical signals as low as two millivolts. The scope's accuracy is rated within ± three percent on both horizontal and vertical measurements.

The IO-3220 oscilloscope is sold in kit form for $689.95. A factory-assembled version, the SO-3220, sells for $995.00. For more information on this portable oscilloscope, contact *Heath Company, Dept. 350-455, Benton Harbor MI 49022.* Reader Service number 489.

LOW-POWER WIDEBAND ANTENNA

Grove Enterprises has announced that their scanner beam antenna, the **ANT-1**, works for low-power transmitting as well as receiving. The beam works on 144-148 MHz, 220-225 MHz, and 420-450 MHz. The average vswr is 1.6:1. Because of its highly directional design, forward signal radiation is "targeted" towards distant repeaters or base stations, increasing the range of low-power transceivers.

For more information about the **ANT-1**, priced at $49.95, contact *Grove Enterprises, Dept. C, Brasstown NC 28902; (800)-438-8155.* Reader Service number 485.

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randallstown MD 21133

Last month I described what may be the ultimate in RTTY output devices: a synthesized voice. Using the new Votrax Type 'N Talk, a self-contained speech synthesizer, and a 6800 computer, this setup allows conventional RTTY to be presented to the operator not as text on a page or view screen, but as an easily understandable computerized voice, capable of pronouncing whatever is sent. This month, let's look at the programming.

The program is written for my 6800 system, which, in its current state of evolution, uses the GIMIX GMXBUG version 3.0 monitor, the GIMIX VDM, and a Smoke Signal disk system, running under DOS68 version 6.1. Along with the video board, assigned to port #4 in the GIMIX system, GMXBUG supports a printer or other output device on either port #3 (serial) or port #4 (parallel). Output vectors are provided to direct data to the VDM, printer, or both. By connecting the Type 'N Talk to port #3, as a serial device running at 1200 baud, we can take advantage of this capability in the demonstration program. Lacking this feature, as in a system using another monitor, separate video and speech output routines could be used with minimal rewriting.

The program itself follows the flowchart presented last month fairly closely. Beginning at $0100, the first chores taken care of are housekeeping: clearing the screen, setting the GIMIX-software-controlled bell to a high pitch and short duration, and initializing the PIA for input. The output vector is also set so that both the screen and voice are initially active.

The actual receiving loop is next down the line. The keyboard is checked for input first. If there is no data found (we will cover what happens when there is input in a little bit), the PIA is checked. The RTTY input is fed to the least significant bit of the "B" side (B0) of a PIA located in port #5. If a START pulse is not found, then a loop back to the keyboard check is executed. By the way, since we are interfacing via an RS-232-type line to the demodulator, recall that the START, which is sent as a "0" level (or space), is represented by a positive voltage. Thus, reading a "1" on the B0 line translates to a space; a "0" is mark, the resting condition.

Once a START pulse is found, a counter is set up and five data pulses are read in. The step-by-step process is covered in the remarks in the program source listing. After screening for case shifts, spaces (which initiate a downshift-on-space), and carriage returns, otherwise unremarkable letters are decoded in a simple indexed table lookup.

The ASCII character, once retrieved from the table, is output by way of the GIMIX OUTCHR routine. As stated above, this routine will vector to either the screen only, the printer (voice) only, or both. However, I only provide the facility within this program to select screen only or screen and voice.

Now, let's get back to keyboard input. I wanted to provide a way to give commands without worrying over accidentally hitting a key and messing something up. So, in the best tradition of secure devices, only one key is recognized while receiving: the ESCAPE key. Hitting any other key is ignored. Striking the ESC key results in two effects. A flag, called the Command Flag (CMDFLG) is set to "1". This indicates that an ESC has been

hit, and that the next keyboard input should be examined as a command character. Then the local bell is rung, to verify receipt of the ESC.

Once the Command Flag has been set, several commands will be recognized by the system. A look at them reveals: V = voice *on*; S = silent—voice *off*; C = caps mode *on*; D = caps mode *off*.

The voice on and off commands are handled by storing a $01 or $00 in the output vector, respectively. The CAPS mode of operation was touched on last month, but deserves another word now. In the conventional mode, CAPS off, words are pronounced as they are spelled. However, groups of letters which are unpronounceable are still attempted, no matter how mangled the effort. Thus, a typical RTTY sign off, such as "N3BRD DE WA3AJR BCNU KKKK," is pronounced. . .well you get the picture if you try it yourself. To get around this problem, a CAPS mode is available, in which groups of capital letters will be spelled out one by one. This is exactly what we need in a RTTY program, and the "C" and "D" commands allow you to turn this mode on or off as needed.

One other command is recognized, by the way. Sending a second ESC will terminate the program and return to DOS. Just provides a clean getaway, if you follow me. Sending any other character will clear the CMDFLG and send nothing out to the Type 'N Talk or VDM.

Granted, this demonstration program is just that, a demonstration. But I feel it shows the kernel of a system that would be useful to many hams — especially visually-handicapped ones.

One feature of this column that many of you have expressed a particular fondness for is the range of material covered. I don't want to disappoint you, so let's go from high tech to basics. Bob Henry, a Boston MA reader, dropped me a line with two good questions. He begins by asking what a "cursor" is for. For the uninitiated, the cursor is the little box, blinking or solid, or sometimes an underline, that scoots along on a video screen just ahead of where you last typed. Why? Try to imagine a typewriter, Bob, where the whole page was somehow suspended in front of you. When you hit the keyboard the characters are placed on the page in order, but that little plastic thingy that normally sits dead center, and through a hole in the center of which the typebar hits the paper, is missing. How do you know where you are? Where to space? If a new line has started? With a typewriter all that information is provided by that guide and the position of the carriage. With a video screen, there ain't no such guide. That is what the cursor is for!

Bob's other question involves an item touched upon above: unshift-on-space. Recall that on RTTY, using five-level Murray code, two cases — letters and figures — are available. Now, if you miss a "LTRS" or "FIGS" code, the proper case will not be selected, and gibberish will result. On ham RTTY, numeral groups are rarely sent. The odds are that if a space is sent, what follows is in the letters case. Let me illustrate. If I send "DE WA3AJR IN MARYLAND," recall that the "3" is preceded by a FIGS and followed by a LTRS. If that LTRS is missed, what prints out is "DE WA3-'4 8, .-46)-,$", all after the 3 being in figures case. With downshift on space, the first space forces letters case, and "DE WA3-'4 IN MARYLAND" results. Less is missed.

Program listing.

Atco NJ 08004

COUNTY HUNTERS SSB CONTEST
Contest Periods:
0001 to 0800 GMT May 1
1200 GMT May 1 to 0600 May 2
1200 to 2400 GMT May 2

Please note the two 4-hour rest periods. Mobiles may be worked each time they change counties or bands. Mobiles that are worked again from the same country on a different band count for point credit only. Mobiles that are contacted on a county line count as one contact but 2 multipliers. Fixed stations may be worked by other fixed stations only once during the contest. Repeat QSOs between fixed stations on other bands are not permitted. Fixed stations may be worked by mobiles each time they change counties or bands. Repeat contacts between mobiles are permitted provided they are on a different band or county. Mixed-mode contacts are permitted provided that one station is on SSB. Contacts made on net frequencies will not be allowed for scoring in this year's contest.

EXCHANGE:

Signal report, county, and state or country.

FREQUENCIES:

Suggested frequencies are as follows: 3920-3940, 7220-7240, 14275-14295, 21375-21395, 28625-28650. There will be a "mobile window" of 10 kHz on the following frequencies: 3925-3935, 7225-7235, 14280-14290. Mobiles will be in this 10-kHz segment and fixed stations are asked to refrain from calling "CQ contest" in the mobile window. After working mobiles in the "window," fixed stations are requested to QSY outside the "window" to work fixed stations in the contest. This will allow the mobiles running lower power a chance to be heard and worked in the contest. There will be a special effort to work DX on 28.636 by mobiles.

SCORING:

Contact with a fixed US or Canadian station = 1 point; contact with a DX station (KL7 and KH6 count as DX) = 5 points; contact with a mobile station = 15 points. The multiplier is the total number of US counties plus Canadian stations worked. The final score is this multiplier times the total QSO points.

AWARDS:

MARAC plaques to the highest scoring fixed US or Canadian station, DX station, and top 2 scoring mobile stations. Certificates to the top 10 fixed and mobile stations in the US and Canada, and to the highest scoring station in each DX country.

ENTRIES:

Logs must show date and time, station worked, reports exchanged, county, state, band, claimed QSO points (1, 5, or 15), and each new multiplier must be numbered. Logs and summary sheets are free for a #10 SASE or SAE and appropriate IRCs. Write John Ferguson WØQWS, 3820 Stonewall Ct., Independence MO 64055. All entries must be received by June 15th to be eligible for awards. DX entries should use air mail. Winners will be announced at the 1982 Independent County Hunters Convention during July and in the MARAC newsletter.

CALENDAR

Dec 11-12	ARRL 10-Meter Contest

SEVILLE WORLDWIDE CONTEST
Starts: 1600 UTC May 1
Ends: 2000 UTC May 2

This contest is sponsored by the Seville (Spain) City Council and organized by the Seville Radio Club. Only single-operator entries are eligible. You may operate 24 hours of the 28-hour contest period, with 4 hours of rest taken in one or two periods. Contacts are allowed on SSB and CW, but a station may be worked only once per frequency band.

BANDS:

80 through 10 meters.

EXCHANGE:

RS(T) plus QSO number beginning with 001.

MULTIPLIER:

DXCC countries worked on each band.

POINTS:

Contacts between stations in the same country count 2 points. Contacts between stations in different countries count 3 points. Exception: Contacts between EA, EA6, EA8 and EA9 count only 2 points.

SCORING:

Total QSO points times sum of multiplier points.

AWARDS:

Certificates will be awarded to the top-scoring station in each continent, each country, and each W/K, VE, JA, and EA call area. The Seville City Council will award an all-expense paid trip to Seville's April Fair Feast to the top-scoring EA and non-EA stations.

ENTRIES:

All times must be in UTC. Indicate multipliers in your log the first time they are worked on each band. Make a separate log and dupe sheet for each band. Include a summary sheet containing scoring information for each band, a station description, and a signed declaration that you have observed the contest rules and the regulations for amateur radio in your country. Please include your comments and photographs.

Entries must be postmarked no later than June 30th. Send entries to: Seville Worldwide Contest, Radio Club Sevilla, PO Box 555, Sevilla, Spain.

DISQUALIFICATION:

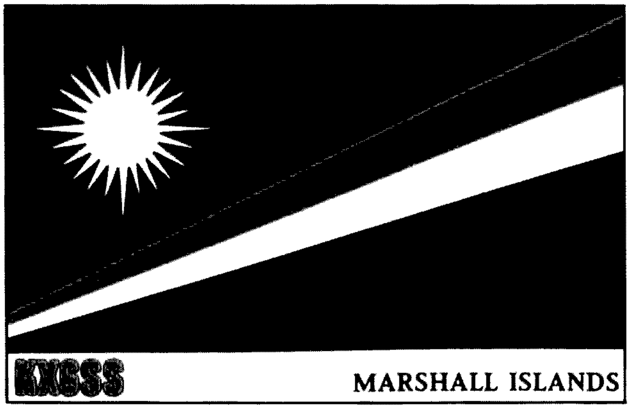
Violation of the contest rules, violation of amateur radio regulations, unsportsmanlike conduct, excessive duplicate contacts, or unverified QSOs will be deemed sufficient cause for disqualification. Decisions of the Contest Committee are final.

MICHIGAN QSO PARTY
Contest Periods:
1800 GMT Saturday, May 15 to 0300 GMT Sunday, May 16
1100 GMT Sunday, May 16 to 0200 GMT Monday, May 17

This year's QSO party will be sponsored by the Oak Park ARC. Phone and CW are combined into one contest. Michigan stations can work Michigan counties for multipliers. A station may be contacted once on each band/mode. Portable mobiles may be counted as new contacts each time they change counties.

EXCHANGE:

RS(T), QSO number, QTH as



QSL OF THE MONTH: KX6SS

The colorful flag of the Marshall Islands provides an attractive design for the QSL of Keith R. Merrick KX6SS. Keith also holds callsigns KG6SS and WA1GYS.

To enter our QSL of the Month Contest, put your card *in an envelope* and mail it, along with your choice of any book from *73*'s Radio Bookshop, to *73 Magazine*, Pine Street, Peterborough NH 03458, Attention: QSL of the Month. Entries which are not sent in an envelope (the Postal Service does *occasionally* damage cards) and do not specify a book will not be considered.

state, country, or Michigan county.

FREQUENCIES:

Phone—1815, 3905, 7280, 14280, 21380, 28580.

CW—1810, 3540, 3725, 7035, 7125, 14035, 21035, 21125, 28035, 28125.

VHF—50.125, 145.025.

SCORING:

Multipliers are counted only once. Michigan stations score 1 point per phone QSO and multiply by the total number of states, countries, and Michigan counties. Each CW contact counts 2 points; KL7 and KH6 count as states; VE counts as a country. Maximum multiplier is 85.

Others take QSO points times the total number of Michigan counties. QSO points are 1 point per phone QSO and 2 points per CW QSO. Maximum multiplier is 83.

All stations score 5 points for each club station contact with W8MB.

VHF-only entries: same as above except multipliers per VHF band are added together for total multiplier. Score 5 points for each OSCAR QSO. No repeater contacts are allowed.

AWARDS:

Michigan trophies to high Michigan score, high Michigan (Upper Peninsula) score, high aggregate club score. Plaque to high VHF-only entry and high mobile. Certificates to high score in each county with a minimum of 30 QSOs. Out-of-state high trophy and certificates for high score in each state and country. Added this year is a trophy for the highest scoring Michigan multi-operator score.

ENTRIES:

A summary sheet is requested showing the scoring and other pertinent information, name and address in block letters, and a signed declaration that all rules and regulations have been observed. Michigan stations include club name for combined club score. Party contacts do not count toward the Michigan Achievement Award unless one fact about Michigan is communicated. Members of the Michigan Week QSO Party Committee are not eligible for individual awards. Decisions of the Contest Committee are final. Results will be final on July 31st and will be mailed to all entries. Mailing deadline is June 30th to: Mark Shaw K8ED, 3810 Woodman, Troy MI 48084.

MICHIGAN ACHIEVEMENT AWARD

This will be the 24th year that hams have had their own program to publicize Michigan and its products. Just as for past years, the Governor will award Achievement Certificates to hams who take part in telling the world of Michigan's unlimited resources, opportunities, and advantages. Certificates are awarded on the following basis:

1. A Michigan ham submits log information and names and addresses (if possible) of 15 or more contacts made to out-of-state or DX hams with information regarding Michigan.

2. An out-of-state ham, including Canada, submits log information and names and addresses (if possible) of at least five Michigan hams who relate facts to him about Michigan.

3. A foreign ham, excluding any resident of Canada, submits the call letters and name and address plus log information for at least one Michigan ham who has told him about Michigan.

Only QSOs made during Michigan Week, May 15-22, will be considered valid. All applications for certificates must be postmarked by July 1st and mailed to Governor William Milliken, Lansing MI 48902.

MT. SAINT HELENS QSO PARTY
Starts: 0001 GMT, May 22
Ends: 2359 GMT, May 23

The Clark County Amateur Radio Club, W7AIA, is pleased to announce the second annual QSO party marking the second anniversary of the cataclysmic explosion of nearby Mt. Saint Helens. This disastrous volcanic eruption took the life of Reid Blackburn KA7AMF, who was an active member of their club. Reid was monitoring a USGS observation station near the base of the mountain at the time of the eruption.

Any amateur station making one contact with W7AIA during the two days of the QSO party will be eligible to apply for the Mt. Saint Helens Award, a color certificate featuring a photograph of the awesome eruption of the volcano on May 18, 1980.

Look for W7AIA on the following frequencies (plus or minus QRM): SSB—3895, 7230, 14280, 21360, 28505; CW—3705, 7105, 21105, 28105; VHF—various Vancouver and Portland area repeaters.

To apply for the award, send log information or QSL card and $2.00 (or 8 IRCs) to: Award Manager, W7AIA, PO Box 1424, Vancouver WA 98668. All proceeds from the award will go to the Reid Blackburn Scholarship Fund which has been established by the *Columbian*, a Vancouver newspaper. So far, 647 amateurs have applied for the award, which has provided for a $1,000 contribution to the scholarship fund.

Kansas Amateur Radio

Public service in local and worldwide communications

NEWSLETTER OF THE MONTH

Amateur radio publications don't have to be either strictly local or strictly national in scope. This month's winner, *Kansas Amateur Radio*, is a good example of a regional publication.

Editor (and owner) KC0GL publishes *K.A.R.* quarterly in a magazine format. The January issue is printed on glossy stock and is 24 pages long. The layout is neat and the graphics are good; it's a professional-appearing publication. *Kansas Amateur Radio* covers what its name implies: the whole range of ham radio activities in Kansas, including net and club news, information about Kansas hams, and occasional technical articles.

This unique magazine is funded by reader contributions and a small amount of advertising revenue. It's a strictly non-profit operation that relies almost totally on reader support, both financial and editorial — as KC0GL puts it, "if you write it, we will print it!"

A lot of small clubs don't have enough going on to warrant a full newsletter each month. Support of a publication like *Kansas Amateur Radio* may be a more practical way for some clubs to get their news into print than undertaking the effort required to put out a good club newsletter. A group of clubs might even consider banding together to produce a cooperative newsletter. There's strength in numbers.

REVIEW

ICOM'S IC-720A TRANSCEIVER

Although the four buildings at *73 Magazine* are each more than a mile apart, no telephone is needed when new equipment arrives for review. The *73* hams start forming lines the minute word gets around that equipment has arrived. Responding to that call, I was informed that the senior staff was so pleased with my previous reviews of dummy loads, power supplies, and BNC-to-garden-hose adaptors that they were going to give me a shot at a real radio.

Real radio is an understatement when it comes to Icom's newest all-mode, general-coverage transceiver, the 720A. This state-of-the-art solid-state rig should fill the bill for just about all devotees of the various modes of amateur communications available to us today on the HF bands. The first two days that the rig was available to me, it was put to use at W2NSD/1 where it was compared to several other transceivers in the station at the same time. In typical Icom fashion, the 720A's receiver outperformed all others — no mean feat when you consider that the Icom has a general-coverage receiver covering 100 kHz to 30 MHz.

The 720A arrived at my station the evening that the ARRL 10-meter contest started and I thought that I would attempt to put the rig through its paces during part of the contest. As it came from the box, 15 minutes prior to the start of the contest, those familiar words "some assembly required" echoed in my mind. The separate power supply (IC-PS15) attached to the 720A with no problem. Two of the phono jacks, on the rear panel, serve dual functions. As it comes from the box, these jacks are set up to provide an input for a low-band antenna and transverter/scope output. If you wish to use a linear amplifier, you must change the position of an internal connector, converting the function of these jacks to provide ALC and relay outputs. The conversion of these jacks required a few minutes study of the manual and less time in effecting the change.

With a few minutes left before the start of the contest, I thought I would take a look at the general-coverage frequencies. At that time of night, reception was good on the lower bands. I was surprised at the fidelity of the AM reception with only the standard filter in place.

My first encounter was with a Colombian station on 5 MHz playing traditional music. Having lived in Colombia for several years, it brought back memories and made me an instant SWL nut. Other treats in the first tour around the bands were an Austrian Christmas music special, a Spanish-language discussion of solar flux, a British Broadcasting Company London *Times* news program, a Portuguese discussion of the economic situation in the United States, and, of course, the old standby, Radio Moscow, with an editorial on the United States' deployment of the neutron bomb in Europe. No tour would have been complete without a stop on the low end of 8 MHz where the CW maritime traffic, with its near-perfect code, is a great place to increase or maintain your code speed.

Icom's IC-720A transceiver alongside the PS-15 12-volt power supply.

An interesting feature of the 720A was noted during this tour. While listening to one of the AM broadcasts, I noted that our old friend, the Russian woodpecker, was as prominent here as he is on the ham bands. Out of curiosity, I turned on the noise blanker and watched the interfering signal fall from 20 dB over S9 to S3. I still knew the offending signal was there, but it was much less bothersome.

Looking up at the clock, I found that the contest was already four hours old (later diagnosed as SWLer's disease). I decided to get a good night's rest and tackle the pileups in the morning. At first light I was on the bands. My first contact was W2NSD/1, 5-9 New Hampshire. Not bad, but I decided to use my limited time to hunt for countries. In eight hours, I racked up 47 countries and got a feel for how the 720A performed.

Operator's Manual

The first thing that impresses the new owner of a 720A is the clarity of the operator's manual. It begins with a concise walk-through of all controls and external connections (more than 50). It next provides detailed explanations of the major controls. A description of the circuit operation follows, remarkably understandable for a rig of this complexity. The section on maintenance and adjustments, along with photographs, covers most problems that might be encountered. While the schematic is small, a large-scale parts layout, in four colors, will prove invaluable for repairs.

My concern for the understandability of the owner's manual is sparked by the fact that I am a rural ham, living more than seventy miles from the nearest ham store and doing most repairs at home. With the 720A's manual, I would have no qualms about undertaking most repairs in the shack.

Icom Pioneers Again

The radio itself is small, measuring 4" × 9" × 12" and engineered to maximize the use of space. It appears to be most functional when placed at eye level. With the 720A, Icom introduces a pioneering method of function and mode selection, similar to the system used by many pocket calculators. Pushbuttons replace many of the knobs used by old-fashioned rigs. Several of the controls are dual-function. While first impressions yield the feeling that you will never understand all of the controls, a few hours of use will convince you of the functionality of this method as you quickly jump from band to band, change modes, and select filters with this new system.

The receiver, unquestionably the hottest I have ever used, utilizes low-noise FETs in the rf amplifier to aid sensitivity and double conversion, with high side injection and steep-skirted filters for maximum selectivity. The receiver covers 0.1 to 30 MHz in 1-MHz steps. A two-position button allows you to step through the covered frequencies, stopping at ham bands only or at any 1-MHz segment. The operating frequency is determined by a microprocessor-controlled PLL. One of the most interesting features of this radio is a low-pass filter unit which employs a motor-driven rotary relay-switching circuit that selects various filter components for each band. During receive, the low-pass unit offers a high degree of adjacent channel rejection; during transmit, it removes harmonic components. The relay also delivers different control voltages to a plug on the rear panel for each band, thus allowing automatic band change for a linear amplifier and automatic antenna selection with external relays.

Operating Controls

The number of controls offered by the 720A provides maximum flexibility but makes description of the actual ease of operation difficult. In order that my written description does justice to the user-friendly 720A, the controls will be divided into four groups.

- Frequency selection. This group includes band-stepping switches, the switch to select one of the two vfo's available, main tuning knob, tuning-rate select buttons, and RIT button.
- Mode Selection. These include CW, SSB, AM, FM, RTTY, and a reverse-sideband select button.

- Ancillary controls. These include the transmit/receive switch, af and rf gain controls, microphone and power output controls, noise blanker, pass-band tuning, and attenuator.
- Display. These include operating frequency, mode, sideband (u or l) and LEDs to indicate that certain functions or filters have been selected.

Operation

SSB and CW operation is straightforward. The frequency selection is made easy by the use of three tuning rates. Major changes can be made with the tuning speed button at a 1-kHz rate. The two other rates are 100 Hz and 10 Hz. The tuning knob is equipped with an adjustable brake that controls the friction on the knob. As it came from the factory, mine was too loose and had to be tightened. The rig is equipped with two vfo's and operation may be on either one or both (split), removing the need for an external vfo.

In this time of crowded band conditions, three features of the 720A make it an ideal operator's rig. The attenuator not only adds a 10-dB pad to the receiver front end, but also removes the rf amplifier. This reduces interfering signals and yields more stable reception. Pass-band tuning (PBT) accomplishes with one control what it takes other rigs two or three to do. PBT narrows the bandwidth (selectivity) of the frequencies that will pass through the crystal filter. This effectively reduces interference from nearby signals. The noise blanker, as I mentioned, is effective in reducing the interference from the woodpecker as well as the usual pulse-type trash such as ignition noise. Living out in the country where automobile traffic is about as common as QSL cards from BY-land, I parked my Subaru under a wire antenna and let it idle. If you are not familiar with this car, it is the noisiest (rf-wise) that you will run into. Letting it idle at 2000 rpm, I returned to the receiver and found the blanker to be effective.

The transmitter lived up to my expectations on SSB. With the obligatory "this is with the processor on" routine, I found that the processor had an above average or acceptable rating from the listeners. The VOX worked with no adjustment and it was not necessary to go under the top access lid.

Speaking of "under the lid," in addition to the fifty some odd controls and jacks that the 720A has on the outside, a convenient top access lid houses additional controls. CW sidetone, meter-function select, and VOX control, that require seldom adjustment, are housed under this top lid.

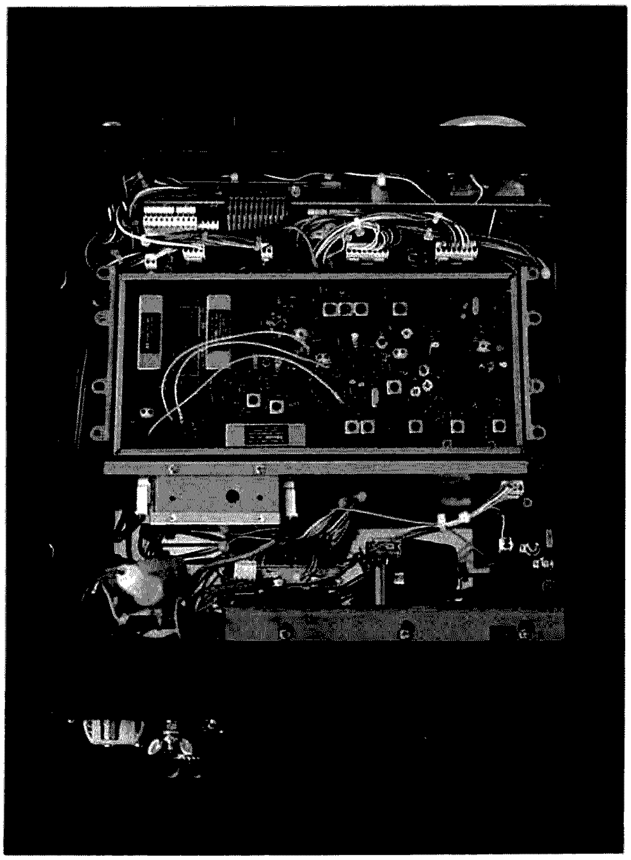
CW operation is just as easy as SSB. The rig did not have the optional 500-Hz filter, but the 1.1-kHz filter provided proved to be adequate for casual use. Upon selecting the CW mode, an LED indicates the filter width and the PBT functions as it does on SSB, allowing the PB width to be narrowed by 800 Hz. Semi-break-in is possible using the VOX switch.

Other Modes

The 720A is equipped for FSK operation and narrow shift tones are available to be sent to a terminal unit. AM operation had to be tried since there is an abundance of 75-meter phone stations here in the Northeast. Reports of "broadcast quality" were heard more than once, giving me the interest to look into this mode further. During operation in this mode, the meter measures carrier power and the operator is cautioned that if he expects to operate for more than ten minutes, power should be reduced to the 70% level.

The finals are protected by a circuit that reduces power in an inverse ratio to swr. In addition, there is a cooling fan that is activated during the transmit mode by a thermal switch. The operator's manual cautions you that should the fan go to high speed, you should *stop* operating at once. I must admit that prior to operating this radio I was a "tube final" type and somewhat nervous about solid-state finals. As I spend most of my operating time on wire antennas, using a tuner, I approached my first 720A band change with trepidation. Relieved by the rapid response of the protection circuit, I adopted a more cavalier attitude with later changes. Since I spend a good part of my time chasing HK3DMD around the bands trying to link up for our regular sked, I can now appreciate the benefits of quick band changes offered by the 720A's solid-state finals.

In summary, the Icom 720A, in the hands of this operator, has proven to be a versatile and practical ham rig. In the course of two months' operation, no major problems were encountered. While not inexpensive, the unit's distinctive features gave me hours of enjoyment and broadened my perspective. The proof of the pudding is in the eating. Should you doubt my opinions, go to your nearest dealer and try the rig yourself. I guess the strongest case for ownership of the 720A is to ask if anyone wants to buy my old rig.



Top view of the 720A. The i-f module's cover has been removed, showing the location of the crystal filters.

The Icom IC-720A and matching PS-15 power supply have a list price of $1498. For more information, contact *Icom America, 2112 116th Ave. NE, Bellevue WA 98004.*

KB1T CONTEST CALENDAR

There was a time, not too many years ago, when calendars were plain and ordinary. Functional, yes, but not very exciting. All that's changed. The walls of our homes and offices are now covered with calendars for cat haters and cat lovers, calendars from the Sierra Club and the oil companies, Right to Life and Playboy Philosophy calendars, even calendars devoted to pictures of polar bears (no kidding!). At long last, radio amateurs can join the calendar craze with one of their very own: the Contest Calendar from KB1T Radio Specialties.

The Contest Calendar is both functional and beautiful. On the functional side, it's a large, 18- x 18-inch, single sheet calendar, showing all 12 months at once. The center of the calendar features a great circle map of the Earth, centered on the USA, a handy aid to pointing your beam. Arrayed around the map are the individual calendars for the 12 months of the year. The weekends of major contests are highlighted in red with an abbreviated name of the contest and the mode (CW, phone). On the 1982 version, my count showed 28 contest weekends listed. The arrangement of the calendar on one sheet and the highlighting of the contest weekends make it easy to plan for upcoming oper-

ating activities—or anything else—at a glance.

And beautiful? The Contest Calendar is a work of art. The graphic design is bold, uncluttered and elegant. The entire calendar is printed on chromed mylar with the map in black. The 12 individual calendars have white backgrounds, with black numerals and red for the contest listings. It is the first and only ham shack accessory I have owned that non-amateurs seem to appreciate as much as fellow hams. It seems to draw more than its share of approving comments.

The Contest Calendar comes with four small adhesive tabs, allowing it to be mounted on a wall. I suspect many owners are framing theirs, however. Any active amateur, especially the contester, will appreciate the Contest Calendar. It's priced at $4.50, from *KB1T Radio Specialties, Box 1015, Amherst NH 03031*. Reader Service number 493.

PACKET RADIO BOOK

The preface to *Packet Radio*, published by Tab Books, Inc., begins by asserting, "This book was written to provide an easy entry into the utterly fascinating world of packet radio." I'm not sure that any single volume could give an *easy* introduction to this highly complex subject, but this book comes pretty close. Actually, it is must reading for anyone even mildly interested in RTTY, networking, or computer communications in general.

There is a wealth of practical information here that authors Robert Rouleau and Ian Hodgson give merely as a background to the main subject. They offer, for example, a fairly lively review of the RS-232C interface, with lots of discussion of the vagaries of interfacing nonstandard equipment. I for one was thrilled to discover that there is a pair of inexpensive chips available which convert TTL-level signals to RS-232C and back again!

The chapter on resource sharing via multiplexing should be read by everyone. It's only a basic introduction to the subject, but it is fascinating to someone who has never considered the subject before (which is to say, most hams!).

The chapters covering packet itself are solid and meaty—I won't reveal the chapter titles because they might scare off the faint-hearted. They sound more formidable than they really are.

The material on high-speed data transmission via HF radio is must reading for any ham who dreams of 9600-baud QSOs. The problems of bandwidth, S/N ratio, path loss multipath, Rayleigh fading, propagation delay distortions, and woefully unsuitable transmitters and receivers are discussed in a matter-of-fact manner. If you dream of a quick and dirty improvement to our present RTTY system, a read through this section will be a sobering experience.

The bottom line, though, is that packet techniques are being used, today, and with reasonable success. To find out more, buy this book! For information, contact: *Tab Books, Inc., Blue Ridge Summit PA 17214*. Reader Service number 496.

The CES 635 Microdialer. (Photo by KA1LR)

THE CES MICRODIALER

For those who have never encountered an autodialing microphone before, it is a device designed to store several phone numbers and feed them into an FM transceiver at a predetermined speed at the press of a button. This is the basic function it must perform—but manufacturers and users alike soon discover that an autodialer must have several other features to perform adequately in the real world.

Like the Heathkit μMatic memory keyer (to be reviewed in June), the CES Microdialer is a second generation microprocessor-controlled device designed to make life a little easier for the amateur radio operator. Also like the Heathkit, the Microdialer has solved many of the problems experienced with the generation of devices that preceded it.

One of the most striking improvements incorporated into the Microdialer is found in its layout. It makes sense to have the buttons and the mike element on the same side of the microphone. Several microphones have the touchtone™ buttons on one side and the mike element on the other. These must be hung up carefully, to avoid pressing one of the buttons by accident. This is a small point, however, compared to some of the other problems the Microdialer solves.

Some owners of earlier autodialing microphones were quite chagrined to discover that their mikes occasionally suffered a glitch which locked their rig in the transmit mode. Hard luck if it happened when the rig was unattended! It was clearly injurious to the microphone, transceiver, and the blood pressure levels of others trying to use the frequency. CES cured the disease by removing the regulator chip (a source of heat) from the mike, putting in the radio instead, and tying the microprocessor's reset pin to the hangup hook. As long as the mike hanger on the vehicle's dashboard is grounded (and you use it!), there is no chance of an accidental transmission. Grounding the reset pin also lowers the mike's current drain from 120 mA off-hook to 60 mA on-hook. The dashboard in my car is plastic, so I simply ran a wire from a bolt in the firewall to one of the screws on the mike hanger. PL™ users should note that there is an extra conductor in the mike cable which can be used to enable a PL decoder when the mike is hung up and disable it when it is removed from its hanger. Nice touch!

Programmed to Please

The Microdialer really shines in the ease-of-use department. For example, when you dial a number in the automatic mode, the mike keys up the rig for .3 seconds before sending a tone—sort of a "look out equipment, here come some tones!" This feature alone allows me to use the Microdialer on several repeaters that won't accept my other dialer, which keys the PTT line at the same instant it sends the first tone.

Another welcome feature is the programmable pause. This allows you to program the autopatch access code (up to three digits) and a phone number into the same memory. The mike dials the access code, switches back to receive for two or three seconds so you can make sure that the dial tone is there, and then keys the transmitter and dials the number. If your repeater has some perverse speed requirements, you can program

the mike to send the access code at one speed and the phone number itself at another. And to make all this happen, all you have to do is push "•" and one of the numeric keys. The looks of envy you'll get from other hams when you set all this in motion are worth every penny you pay for the mike! If you are motivated by more practical considerations, consider that you can easily call home, the police, or whatever with the Microdialer, while your vehicle is in motion, without taking your eyes off the road for a second.

Entering numbers into memory is no easier or harder than with other autodialers we have tried. Memories 1 through 5 hold up to eleven digits, and 6 through 0 hold up to seven. Dialing speeds from one to eight digits per second can be programmed, and I am happy to report that there are several touchtone decoders in common use which can cope with the highest speed.

One repeater I use is plagued by a childish individual who frequently transmits tones while a user is trying to dial a number. With the Microdialer, I could bring up the patch and dial the number before our "friend" could find his or her mike.

Installing the Microdialer

If the Microdialer has any weakness, it lies in the simple fact that it involves some installation. Let's face it: There are a lot of guys who are too lazy to use a soldering iron. If a microphone doesn't come with the right plug for their rig attached, they aren't interested. To them I say, turn the page and read another article.Those of you who aren't afraid of a little work, read on!

The first thing you have to deal with is the regulator. CES solved a major problem by removing it from the mike case, but they created a minor one while doing it. You have to find a spot inside the rig for the tiny board which holds a 7805 regulator and a couple of filter caps. You also have to supply it with an unswitched source of 12 V dc. If you are using a rig over a year old, this doesn't present any problem, as there is usually lots of room for additions. I chose to use the Microdialer with my Kenwood TR-7730, one of the smallest rigs available. Getting the 12 V dc was easy—finding a spot big enough for the regulator board was not. There is a nice opening at the rear of the rig that Kenwood suggests is good for a CTCSS encoder. It may be OK for the encoder, but the rf from the adjacent final amplifier added an unhealthy dose of hum to our audio when the regulator board was put there. I finally ended up removing the internal speaker, which I never used anyway. This yielded plenty of room for the microphone's regulator and a Communications Specialists programmable CTCSS encoder/decoder board. I stored the speaker and its mounting hardware in a safe place, in case I wanted to restore it to its original condition. If there's a will, there 's a way, and if it'll fit in a 7730, it'll fit anywhere!

In Use

I found the Microdialer an extremely helpful addition to my mobile VHF installation. Compared to the microphone supplied with the TR-7730, the microphone element itself has a wider frequency response, with a noticeable improvement in lower midrange response. On the negative side of the ledger, it also has considerably less output, requiring the mike gain control inside the TR-7730 to be set much higher than previously required. This means that I cannot easily switch back and forth between the CES and Kenwood microphones.

I also found that the transmitter goes into the transmit mode for a brief moment when my sample is hung up on the grounded hanger. When I say brief, I really mean brief; It has never been long enough to bring up a repeater. I did not try the microphone with other radios, so I cannot say if this is only a problem with my particular installation or could be expected in others as well. In any case, it is not a serious problem, but you should be aware that it is there.

I am particularly fond of the microphone's shape and size. Many microphones must be held carefully, or your hand will cover the element, yielding muffled audio. You have to really work at it to make this happen with the Microdialer. It may be of little consequence to southerners, but dwellers in the land of snow and ice will be happy to hear that the microphone cable is made of a material which stays flexible at a far lower temperature than other cables we have encountered.

Another point worth noting is that when used in the manual mode, the Microdialer behaves like a normal, run-of-the-mill touchtone pad. Certain other autodialers become rather churlish in the manual mode, beeping irritably and locking up for a second or two if you try to make it do something it thinks it shouldn't be doing. Rest assured that the Microdialer is too well-mannered to engage in such loutish behavior!

Conclusion

If you use an autopatch a lot, or frequently access your repeater's control functions, an autodialing microphone can uncomplicate your life. The CES Microdialer incorporates some much-needed improvements over previous units and is priced at $59.95 for a 500-Ω model. The only feature that Is missed is the ability to permanently store a series of numbers on a ROM chip. Maybe next year...

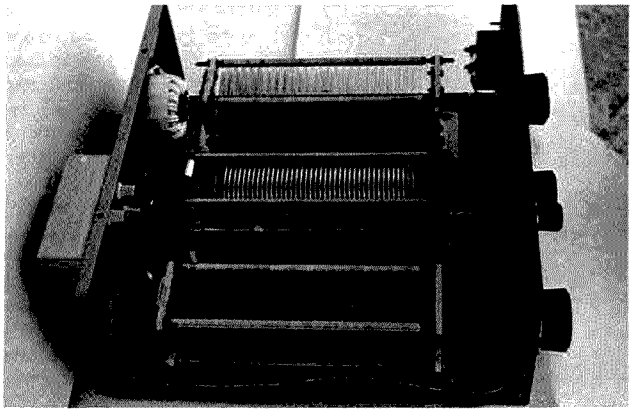
The Heath SA-2060 tuner features two meters. (Photo by N8RK)



Two variable capacitors and a roller inductor form a T-network in Heath's SA-2060 tuner. (Photo by N8RK)

HEATHKIT'S SA-2060 TUNER

It's easy to say that a tuner's a tuner, but if that's so why can you build one for next to nothing or spend over six hundred dollars for a motorized autotuning marvel? The answer boils down to power handling capability and convenience. Heathkit's model SA-2060 antenna tuner represents a good compromise between the extremes of tuner design. Selling for $254.95, it's rated to handle the full legal power limit, contains a built-in wattmeter and antenna switch, and uses a roller Inductor rather than the tapped coil used in many tuners, making it a lot easier to use than that coil-and-jumper-clips device you built as a Novice.

The SA-2060 uses the now standard T-network matching scheme and with Its roller Inductor can provide a match to some loads that tuners using tapped coils simply can't cope with. It

covers frequencies from 160 to 10 meters and can handle random wire or balanced feed antennas. A built-in 4:1 balun helps tame the wild impedances that are sometimes found when using tuned feeders.

When this kit arrived, my first thought was that there couldn't be much involved in building an antenna tuner, since at the minimum only two or three components are required. Well, when Heath tells you that you *build* this tuner, they mean it. It's up to you to assemble the two variable capacitors out of metal plates, ceramic insulators, and threaded rods. The roller inductor also needs assembly, although thankfully the coil itself is prewound.

Heath says that this kit is a three-evening project. That isn't far from the mark, although I spent considerably more time because of a modification I wanted to make (more on that later).

Although the instructions put the capacitor and coil assembly about halfway through the project, I'd suggest putting them together at the beginning so that all the little parts they use are out of your way. Assembly of the capacitors is for the most part very easy and great therapy after a hard day at work. Just keep slipping those little metal plates onto the assembly. It's a lot like threading popcorn onto a thread at Christmastime.

The rf sensing assembly for the wattmeter and the antenna switching circuitry are preassembled in a box which mounts on the back of the tuner chassis. Providing the critical wattmeter circuits already assembled and calibrated was a great move on the part of Heath. Not only did it speed up construction, but it's nice to be able to rely on their calibration (my tests show the SA-2060's meter to read within 5% of other meters used at W2NSD/1). The wattmeter actually uses two meters, one to show forward power on scales of 0-200 or 0-2000 Watts, and the second to read either reflected power (on scales of 0-50 or 0-500 Watts) or swr.

I found the reflected power mode to be easier to use than the swr mode when adjusting the tuner. All that's really necessary is to adjust for 0 Watts reflected power, so there's no need to know actual swr. Having dual meters is very convenient, since some tuning combinations can produce misleading reflected power or swr readings. By keeping an eye on both forward and reflected power, it's easy to spot these conditions and to tune for optimum settings.

The SA-2060 antenna switch provides three positions. One routes the signal through the wattmeter but bypasses the tuner, while the other two select coax-fed antennas which go through both the meter and the tuner circuitry. There's no way, however, to switch the tuner in or out of line on a specific antenna—if you want to run the antenna through the tuner, you must do so all the time. This isn't really such a bad thing, since the tuner does act as a low-pass filter and helps prevent TVI, but it is inconvenient to have to adjust the tuner before using that antenna even if the swr in the part of the band being used is low enough such that the tuner isn't really needed.

There is a serious problem with this antenna-switching scheme if you want to use both coaxial and wire-fed antennas. The random wire/balanced feed terminals are connected to the tuner *before* the antenna switch, with the result that any antenna hooked up to these terminals is always in line and will be paralleled with a coax antenna selected by the antenna switch. This renders the switching system almost useless, since before switching to a coax antenna you have to go behind the tuner to disconnect the wire one. Fortunately, the fix for this problem is rather simple if you're willing to drill a hole in the chassis and change around some wiring (see box and photo).

With the antenna switching changed as described, the tuner is a joy to use. It handles a full kilowatt with ease (although the tuner should be adjusted before running at the power level—no tuner is designed to handle the voltages that may appear when feeding a kW into 15:1 swr!), and it survived the toughest test I can think of. While driving a vee beam with full power on 80 meters, the open feeder arced through a supporting board. The feeder was burned in two and the board caught fire, but the tuner survived this rather severe mismatch with no more than a brief arc between capacitor plates. Never let it be said that we baby equipment at W2NSD/1!

In more normal use at my home station, the SA-2060 has easily matched every so-called radiator I've connected to it, including a very badly mismatched vertical, a more-than-random random wire, and a coax-fed collinear dipole that

SWITCHING MODIFICATION FOR THE HEATH TUNER

The Heathkit SA-2060 antenna-switching problem described in the review is easily correctable.

The purpose of this modification is to disconnect random wire or balanced feed antenna terminals from the tuner circuit unless switch position COAX 2 is chosen.

As originally designed, the random/balanced antenna terminals were connected to the output of the tuner *before* the antenna switch. Thus, if an antenna was connected to either of these terminals, it would always be fed in parallel with any coaxial feed antenna chosen by the antenna switch. To avoid radiating on two antennas at once, it was necessary to disconnect the wire antenna from the back of the tuner when a coax antenna was used, and no antenna could be connected to the switch position selected when a wire antenna was to be used. This arrangement rendered the antenna switch useless to those who use both coax- and wire-fed antennas.

My solution was to move the connection point for the random/balanced terminals from the input of the coax switch to the COAX 2 output of the switch. Now, the wire antenna is connected to the tuner only when the COAX 2 position is selected, and a coax antenna can be used at COAX 1 without fear of feeding two antennas in parallel. The COAX 2 position can still be used to select a coax-fed antenna if no wire antenna is used.

The change involves mounting an additional ceramic feedthrough from the antenna switch box into the tuner chassis. This feedthrough is connected by a short strap to switch lug 6 inside the switch box. Lug 6 is also connected to the COAX 2 chassis connector.

The random antenna terminal is connected to the new feedthrough rather than to capacitor C2 as in the original design. No other internal connection is made to the random terminal. C2 is connected directly to the feedthrough from the switch box which was orginally connected to the random terminal. The additional parts necessary can be ordered from Heath.

After studying the layout of the tuner, the whole process is easier to do than to describe. The only cautions are to drill the new hole with enough clearance to allow the feedthrough to miss the lip of the switch box (see photo for feedthrough location) and to make sure all the rf-carrying straps have as much separation from each other and from the chassis as possible.

An extra feedthrough insulator was added to increase the versatility of Heath's SA-2060 tuner. (Photo by N8RK)

presented a proper match at no given frequency. This tuner replaced another inexpensive commercial one, and I've found the change to be most refreshing. I no longer have problems with being able to almost, but not quite, get a perfect match, and the built-in metering and switching (as modified) have eliminated the need for two other accessories, giving me a little more room on the operating table.

If you're in the market for an antenna tuner that includes some of the convenience features we've come to expect from the high-priced supertuners but still carries a reasonable price tag, the Heathkit SA-2060 may be your answer. The only real flaw with the unit, the antenna switching, won't bother those who don't use wire feeders, and those who do can easily cure the problem. You'll have to invest some of your time in building this tuner, but the results (and savings) can be gratifying.

For more information, contact the *Heath Company, Benton Harbor MI 49022.* Reader Service number 492.

HOBBY VIDEO

Offhand, I can think of only one occasion in my life when amateur radio and commercial video met. Since I need a justification for writing a column about hobby video in a ham magazine, let me tell you about it.

It happened on the day I took my Extra test (the time I passed). I had just left the Federal Building on New York's Varick Street with my interim permit clutched firmly in my fist. As I was making my way over to Washington Square to catch the subway back home, I suddenly noticed in front of me a bunch of klieg lights, cameras, and a typical Greenwich Village street with cars and street signs of an early-1960s vintage.

"Could you hold it a minute, fella?" a man in a light-colored windbreaker asked me.

"Sure," said I. "Hey, what's going on here?" I inquired, asking the obvious, as usual.

The guy in the windbreaker paused for a second, looked me over very closely, and said: "It's okay. Go on ahead. Your clothes fit into the period, anyway." So, with that I slipped between two wooden barriers and continued my eastward march.

I'm about halfway along the block when a taxi comes tearing down the street with a 1959 Chevy sedan in hot pursuit. The cab smashes into a fire hydrant directly across from me and two rough types jump out of the car and put the collar on the taxi driver. It was, of course, a part of a movie—a TV movie, as it turned out. And the Panavision camera caught me as a horrified onlooker. I later saw the movie on ABC, but I guess my scene landed on the editing room floor—I wasn't in the completed film.

So, that was the day broadcast television and ham radio made almost simultaneous appearances in my life. Listen, it may not be the greatest story ever told, but at least it gave me a lead to this month's column.

On a wildly different note, I know someone who is writing a high-school electronics textbook. As a plug for ham radio to a potentially ripe audience, this chap thought he would include some information about the OSCAR satellites in his book. My friend wrote to the ARRL asking for a couple of black and white photographs so that his readers could get an idea of what an amateur-built satellite looks like.

The upshot of his efforts, sad to say, was a letter from HQ saying that the League's OSCAR photos are for use only in their own publications and "are not for dissemination to the general public." Wonderful. So the League doesn't want the general public to know what the OSCAR satellites look like. It's a great boost to our hobby when only hams can find out about OSCAR.

All in all, another tidbit of information to remember the next time a League official lets loose some of that babble about your dues going toward more than just a magazine subscription. Phooey!

I) Opera house seen on "Bravo".... 1 27 10

J) TVRO setup can cost this.......... 28 12 38 14

K) Iraq prefix................................. 24 16

THE ANSWERS

Element 1:
See Illustration 1A.

Element 2:
1—2 There's no Doody in Newington.
2—3 But his agent is.
3—4 Remember? They had those little HTs that never seemed

to be limited in range or vulnerable to jammers.

4—3 Roy Neal works for NBC, Murray Greshner is the cop on *The Odd Couple* and I don't know who the heck Hector Fuentes is.

5—4 Satcom III (not to be confused with its replacement, Satcom IIIR) was lost shortly after launch. Nobody knows for sure where Satcom III is, but I understand they're watching some great movies up on Pluto.

Element 3:

1—True	*The Killers*, in 1963. It was his last acting job—on screen, anyway.
2—False	Time-Life.
3—True	And make that a double, please.
4—True	It didn't work.
5—True	Operated by NBC in New York.
6—False	There is a Channel One, but we call it "6 meters."
7—True	The FCC thought RCA's all-electronic system was somewhat better.
8—True	Smile.
9)—False	Paul Nipkow was granted a German patent for such an instrument in *1884*!
10—True	And I've got a recording of the program to prove it!

Element 4:
See Illustration 2A.

SCORING

Element 1:
Twenty-five points for the completed puzzle, or ½ point for each question correctly answered.

Element 2:
Five points for each correct answer.

Element 3:
Two and one-half points for each correct answer.

Element 4:
Twenty-five points for the completed puzzle, or one point for each correct answer.

So, do you know the difference between a plate and a dish?

1-20 points—Sees only snow
21-40 points—Dish pointed at Earth
41-60 points—Fuzzy picture
61-80 points—Sharp black and white picture
81-100 + points—Closed-circuit image

READER'S CORNER

Last January's puzzle concerning the five stations and their DX schedules provoked a sizable flurry of mail — some of it indignant. As a few of you discovered, there were actually *three* solutions to this puzzle. Here they are:

		M	U	L	T	I	P	O	I	N
T		D	I	S	T	R	I	B	U	T
I	O	N		S	Y	S	T	E	M	
P	I	R	A	T	E	S		D	O	N
T		M	I	S	S		O	U	T	

Illustration 2A.

Expansion of the Telephony Segments of the High Frequency Amateur Radio Service Bands

AGENCY: Federal Communications Commission.

ACTION: Notice of inquiry and proposed rule.

SUMMARY: The Commission proposes to make additional segments of the 14 MHz amateur band available for telephony operation. The Commission is also inquiring about making additional segments available for telephony operation in the other high frequency (HF) amateur bands (those amateur bands between 3 and 30 MHz). Congestion on the frequencies currently authorized for telephony use is causing the employment of this mode to become increasingly difficult. The proposed rules revision would help alleviate this situation in the 14 MHz band. The inquiry looks towards finding a suitable set of frequencies for telephony expansion in the other HF amateur bands.

DATES: File comments on or before July 1, 1982, and reply comments on or before August 2, 1982.

ADDRESS: Federal Communications Commission, Washington, DC 20554.

FOR FURTHER INFORMATION CONTACT: Steve Lett, Private Radio Bureau, (202) 632–7597.

SUPPLEMENTARY INFORMATION:

Adopted: February 11, 1982.

Released: February 24, 1982.

Introduction

1. Notice of Inquiry and Proposed Rule Making in the above-entitled matter is hereby given.

2. The Commission has before it at this time seven petitions for rule making which request that the Amateur Radio Service Rules (Part 97) be amended by provide for the use of telephony operation (emission types A3 and F3) on additional portions of the amateur high frequency (HF) bands—the bands between 3 and 30 MHz. Six of the petitions propose some particular portion of certain bands for additional telephony authorization. Four of the petitions propose that additional telephony privileges be divided among or limited to certain operator classes. The petitions are described in the following paragraphs.

3. RM–3705, submitted by Philip Galasso and received by the Commission on 18, 1980, requests that the frequencies 3750–3775 kHz, 7050–7100 kHz, 14100–14200 kHz, 21200–21250 kHz and 28200–28500 kHz be added to those authorized for telephony in the United States. It further requests that these additional telephony privileges only be granted to Amateur Extra Class operators and that power input during such operation be limited to 250 watts. The petition claims that expansion of frequencies for telephony operation is warranted due to congestion on the currently authorized telephony subbands and under-utilization by U.S. stations of the frequencies proposed for expansion. Lack of use by U.S. amateurs is attributed to incompatibility between telegraphy operation currently authorized for U.S. stations and telephony operation in common use by

foreign stations. Operator class and power restrictions are requested by the petition to help ". . . assure minimum interference to the existing radiotelephone users of these frequencies. . . ."

4. RM-3729, submitted by David Novoa and received by the Commission on June 30, 1980, requests that the frequencies 7075–7100 kHz and 14175–14200 kHz be allocated for exclusive use by Amateur Extra Class licensees and that telephony operation be authorized on these frequencies. This petition also cites crowding on existing telephony subbands and incompatibility of domestic telegraphy operations with foreign telephony operations as reasons for expanding the telephony subbands. The petition further claims that protection for foreign amateurs from powerful U.S. stations is no longer necessary and that foreign stations, in fact, favor a subband expansion which would enable them to engage in an exchange of telephony communications with U.S. stations on a single frequency.

5. RM-3734, submitted by James Simon and William Bennett and received by the Commission on August 1, 1980, requests that the frequencies 3750–3775 kHz, 7050–7150 kHz, 14100–14200 kHz, 21200–21250 kHz and 28400–28500 kHz be made available for telephony use by U.S. amateurs. This petition again cites overcrowding on currently authorized telephony subbands and lack of further need for protection of foreign stations as reasons for its request.

6. RM-3778, submitted for the Willamette Valley DX Club by Robert Herndon and received by the Commission on October 7, 1980, requests that the frequencies 3750–3775 kHz, 7050–7100 kHz, 14100–14200 kHz, 21200–21250 kHz and 28400–28500 kHz be authorized for telephony operation since, it contends, "the United States no longer has the dominant amateur population and there is little reason to think that the expansion of U.S. amateur (telephony) privileges into previously reserved frequencies will result in undue hardship on foreign amateurs." The expansion is necessary, it claims, to relieve congestion on currently authorized telephony subbands.

7. RM-3831, submitted by Ronald Kramer and received by the Commission on November 7, 1980, petitions the Commission to increase the portion of each amateur frequency band between 1.8 and 30 MHz available for voice (telephony) communication and correspondingly decrease the portion of each band available for telegraphy communications. The petition claims this is necessary since the telephony mode is becoming increasingly popular.

8. RM-3833, submitted by Fred Huntley and received by the Commission on January 13, 1981, requests that "Extra Class Amateur Radio licensees be granted radiotelephone operation privileges between 7.100 and 7.150 MHz" and that "(s)uch operation be authorized a maximum power input of 250 watts." The petition proposes that this additional operation be on a shared basis with existing Novice class operations. Relief of congestion and interference on the existing telephony segment of that band is cited as necessitating this action.

9. RM-3860, submitted by the American Radio Relay League (ARRL) and received by the Commission on March 9, 1981, requests that the frequencies 14150–14200 kHz be added to those authorized for telephony use and that operator privileges on the revised telephony portions of the 14 MHz band be changed to the following: 14150–14175 kHz, Amateur Extra Class only; 14175–14225 kHz, Amateur Extra and Advanced Classes; 14225–14350 kHz, Amateur Extra, Advanced and General Classes. The petition cites growing congestion in the present telephony subbands as warranting expansion of the subbands. The operator privilege changes are proposed by the petition in the interest of lessening the impact of telephony subband expansion on foreign amateur operations.

Background

10. The Commission has traditionally designated particular portions of the heavily used HF amateur frequency bands for operation using certain emission modes, while only permitting other modes on different portions of the bands. These designations have served to segregate incompatible operating modes. Since the early days of radio, simultaneous use of incompatible modes on the same frequencies has worked to the mutual detriment of communications using all modes. Placing certain emission modes on different frequencies avoids this type of interference and has the further beneficial effect of indicating to amateur operators where, in the amateur bands, to seek out certain forms of operation.

11. The subband allocations [1] have also been arranged to protect international amateur radio operations. Foreign operators have consistently, in the past, objected to expansion of U.S. subbands for increasingly popular, wide bandwidth emissions such as telephony.[2] They have claimed that such an expansion would create a situation where high powered U.S. stations would overrun low power foreign stations and effectively prohibit the foreign stations from using those bands.

12. Protection of foreign stations has also benefited U.S. operators desiring to contact them using telephony. The U.S. operator can listen for the foreign stations in a portion of the band where strong U.S. signals are not present [3] and then reply on frequencies within the U.S. telephony subbands. The foreign operators then listen for the U.S. stations in the U.S. telephony subbands.[4]

13. Current regulations permit emission type A1 Morse telegraphy operation on all amateur radio frequencies. This unique universal authorization for that mode results from its character as an efficient and widely recognized communications language that can be employed with the simplest type of equipment. In the amateur 160 meter band (1800–2000 kHz) type A3 telephony operation is currently permitted on all frequencies. In all HF amateur bands roughly half of the band may be used for A3 or F3 telephony emissions. The limitations on telephony operation in most of the HF bands were instituted in order to prevent such operation from overwhelming telegraphy operations as well as to protect international operations. Type F1 digitally coded emissions (radioteletype) are permitted in all portions of the HF bands where telephony operation is not permitted since this type of operation is more harmonious with type A1 operation. The only other modes permitted on the HF bands, emission types A5 and F5 "slow-scan" television operation and emission types A4 and F4 facsimile operation, require a bandwidth approximately equivalent to telephony operation and consequently are permitted in the telephony subbands.[5] This current state of subband allocation in the HF amateur bands is the result of the Report and Order in the last proceeding dealing with expansion of the telephony subbands.[6]

14. Small portions of the various subband allocations are reserved for Amateur Extra Class and Advanced Class licensees. These portions were set aside to help provide an incentive for amateurs to upgrade their license operator class. This program of reserved operator privileges resulted from the proceeding dealing with incentive licensing and distinctive call signs.[7]

Proposal

15. The Commission proposes to expand telephony privileges in the 14 MHz amateur band by adding the frequencies 14150–14200 kHz to those currently authorized for such use. We feel this action is warranted due to the extreme congestion experienced by amateurs on the existing 14200–14350 kHz telephony subband. Although the various petitions' requests ranged from a subband that would start as low as 14100 kHz and extend to 14350 kHz, to a subband that would start as high as 14175 kHz and extend to 14350 kHz, we have selected a starting point of 14150 kHz to propose as a compromise between competing objectives. We anticipate that our proposal would provide substantial relief to the current overcrowding in the 14 MHz telephony subband while causing only a minimal disturbance to international operations. The increasing sophistication of equipment used by both foreign and domestic amateur operators leads us to believe that foreign stations should not experience undue interference from U.S. operations and that U.S. amateurs attempting to contact foreign stations should have less difficulty using single frequency operation (as opposed to "split operation") than they have had in the past. We propose retaining the frequencies 14100–14150 kHz for traditional weak signal and other international operations by not changing the modes authorized on those frequencies.

16. Since we do not anticipate a significant detrimental impact on international operations from our proposal, and since we desire to provide the maximum relief possible from the current overcrowding, we propose to make all of the additional telephony subband frequencies available to Amateur Extra Class, Advanced Class and General Class operators. To this end, we have specifically proposed to not change any of the operator privileges. However, we invite comments as to whether it would be desirable to delete from General Class operators the privileges between 14150 kHz and 14200 kHz, and instead, add privileges between 14225 kHz and 14275 kHz to those authorized for General Class operators. In this way, the telephony subbands available to General Class operators will be contiguous. Also, consistent with our action in PR Docket 80–252 to permit the use of television and facsimile on most portions of the HF bands where telephony is permitted, we propose to include the use of type A4, A5, F4 and F5 emissions in the new 14150–14200 kHz subband allocation. We are not proposing a stricter power limitation for the additional subband allocation since we do not feel this would make any significant contribution toward avoiding interference.

Inquiry

17. The 14 MHz amateur band has one of the two smallest telephony subband allocations and is, perhaps, the most popular HF amateur band due to its reliability for long distance communications. Because of these factors, we believe that crowding on this band is severe enough to transcend much of the controversy surrounding telephony subband expansion, and for this reason we have set forth a specific proposal for that band. However, we are not proposing expansion of any of the other telephony subbands between 3.5 and 29.7 MHz because we feel the issues involved are too inadequately defined for us to commit ourselves to any particular course of action. Instead, we invite the submission of comments and supporting information with which these issues may be clarified. The Commission recognizes that the existing telephony subbands are often seriously overcrowded. However, we request commenters to weigh the magnitude of this problem against the issues addressed in the following questions:

A. Would expansion of the telephony subbands have a major detrimental impact on domestic telegraphy operations?

B. Do non-U.S. stations still have a legitimate requirement to be protected, on some frequencies, from U.S. telephony operations?

C. Does the current trend toward the use of transceivers (with a common transmit and receive tuner) make the reservation of frequencies suitable for contacting foreign stations using "split operation" unnecessary or undesirable?

D. Should additional subband allocations for telephony be contiguous with the existing telephony subbands?

E. Would it be appropriate to relocate the existing Novice subbands to new frequencies within the same HF bands in order to make a telephony subband expansion more orderly?

F. Are the current exclusive subbands for Amateur Extra and Advanced Class operators sufficient to meet the goals of our incentive licensing program if all additional telephony frequencies are authorized to General as well as Amateur Extra and Advanced Class operators?

G. How should the recent expansion of the Canadian telephony subband in the 7 Mhz band influence proposals for a U.S. telephony expansion in the same band?

18. We also encourage commenters to make specific recommendations as to what frequencies would be best suited to use for additional telephony privileges and the relative occupancy of those frequencies. Comments about related matters not explicitly mentioned above are also invited.

Conclusion

19. Notice is hereby given that it is proposed to amend 47 CFR Part 97 in accordance with the proposals set forth in the attached Appendix. Notice is also given of inquiry into the matter discussed above.

Procedural Matters

20. For purposes of this non-restricted notice and comment rule making proceeding, members of the public are advised that *ex parte* contracts are permitted from the time the Commission adopts a notice of proposed rule making until the time a public notice is issued stating that a substantive disposition of the matter is to be considered at a forthcoming meeting or until a final order disposing of the matter is adopted by the Commission, whichever is earlier. In general, an *ex parte* presentation is any written or oral communication (other than formal written comments/pleadings and formal oral arguments) between a person outside the Commission and a Commissioner or a member of the Commission's staff which addresses the merits of the proceeding. Any person who submits a written *ex parte* presentation must serve a copy of that presentation on the Commission's

---

[1] The term "subband" is popularly used to describe a segment of a frequency band where authorized modes of emission or authorized operator class privileges are different from those in other portions of the same band. This term is used throughout the text for the sake of clarity.

[2] Depending on the specific emission mode employed, telephony operations in the HF amateur bands occupy a bandwidth roughly between 3 kHz and 7kHz. The more popular telephony modes in use today (principally A3J single sideband) occupy somewhat less than 4 kHz. On the other hand, telegraphy emissions used in the HF bands (both A1 and F1 types) occupy less than 1 kHz.

[3] This portion of a band, where domestic telephony operation is not permitted and where operators listen for foreign stations to contact, is commonly known as the "DX window."

[4] This form of operation where an amateur transmits to a station on one frequency and listens for the station's reply on another frequency is commonly known as "split frequency operation."

[5] Authorization of emission types A5 and F5 "slow-scan" television operation, along with types A4 and F4 facsimile operation, in entire HF telephony subbands was the subject of the proceeding in PR Docket 80–252. See Report and Order, 47 FR 2872, January 20, 1982.

[6] Report and Order in Docket 19162, 37 FR 21325, October 7, 1972.

[7] Report and Order in Docket 15928, 32 FR 12682, September 1, 1967.

Secretary for inclusion in the public file. Any person who makes an oral *ex parte* presentation addressing matters not fully covered in any previously-filed written comments for the proceeding must prepare a written summary of that presentation; on the day of oral presentation, that written summary must be served on the Commission's Secretary for inclusion in the public file, with a copy to the Commission official receiving the oral presentation. Each *ex parte* presentation described above must state on its face that the Secretary has been served, and must also state by docket number the proceeding to which it relates. See generally, Section 1.1231 of the Commission's rules, 47 CFR 1.1231. A summary of the Commission's procedures governing *ex parte* contacts in informal rule makings is available from the Commission's Consumer Assistance Office, FCC, Washington, DC 20554, (202) 632-7000.

21. Authority for issuance of this Notice is contained in Sections 4(i), 303(r) and 403 of the Communications Act of 1934, as amended, 47 U.S.C. 154(i), 303(r) and 403. Pursuant to applicable procedures set forth in Section 1.415 of the Commission's Rules, interested persons may file comments on or before July 1, 1982, and reply comments on or before August 2, 1982. All relevant and timely comments will be considered by the Commission before final action is taken in this proceeding. In reaching its decision, the Commission may take into consideration information and ideas not contained in the comments, provided that such information or a writing indicating the nature and source of such information, is placed in the public file, and provided that the fact of the Commission's reliance on such information is noted in the Report and Order.

22. In accordance with § 1.419 of the Commission's rules, 47 CFR 1.419, formal participants must file an original and five copies of their comments and other materials. Participants who wish each Commissioner to have a personal copy of their comments should file an original and eleven copies. Members of the general public who wish to express their interest by participating informally may do so by submitting one copy. All comments are given the same consideration, regardless of the number of copies submitted. All documents will be available for public inspection during regular business hours in the Commission's Public Reference Room at its headquarters in Washington, DC.

23. The Commission has determined that Sections 603 and 604 of the Regulatory Flexibility Act of 1980 (Pub. L. 96-354) do not apply to this rule making proceeding since the proposed rules would only change operating practice. These changes would not compel amateur operators to purchase new equipment and consequently would have no significant economic impact on them or any small businesses, small organizations or small governmental jurisdictions.

24. It is ordered that the Secretary shall cause a copy of this Notice to be served upon the Chief Counsel for Advocacy of the Small Business Administration and that the Secretary shall also cause a copy of this Notice to be published in the Federal Register.

25. For further information on this proceeding contact Steve Lett, Federal Communications Commission, Private Radio Bureau, Washington, DC 20554, (202) 632-7597.

(Secs. 4, 303, 307, 48 Stat., as amended, 1066, 1082, 1083; 47 U.S.C. 154, 303, 307)

Federal Communications Commission.
William J. Tricarico,
Secretary.

Appendix

PART 97—AMATEUR RADIO SERVICE

It is proposed that paragraph (a) of § 97.61 of the Commission's Rules and Regulations, 47 CFR 97.61, be amended as follows:

In the table in that paragraph, the row beginning with "14200-14350 (kHz)" would be revised by beginning the row with "14150-14350 (kHz)" so that the entire row reads as follows:

* * * * *

14150-14350 ...... A3, A4, A5, F3, F4, F5

§ 97.61 [Amended]

Arlington VA 22207

CORRECTIONS

"The Masher," an article in the March, 1982, issue of *73*, has a capacitor incorrectly labeled. C3 in Fig. 2 and on the parts list should be a 1-uF capacitor.

Power Gain Systems' new product announcement in the March, 1982, *73* had an incorrect phone number. Power Gain Systems can be reached at (318)-325-4754. Since publishing the prices for the coaxial dipole, *73* has learned that the antennas now list for $44.95 and $49.95.

SOCIAL EVENTS

from page 105

include door prizes every hour, indoor vendors, a flea market, and nets and group meetings. Food and drink will be available. Talk-in on 146.19/.79 and 147.86/.26. For further information, write Jack R. Thompson KA4RKS, 637 Wolf Road, Covington KY 41015, or call (606)-291-2153.

MUNCIE IN
MAY 23

The 3rd annual Muncie Area Amateur Radio Club Hamfest will be held on May 23, 1982, from 8:00 am to 3:00 pm at the Ball State University indoor track building, Muncie IN. Tickets are $2.00 in advance or $3.00 at the door. All activities are under a roof and there will be forums, prizes, refreshments, and parking available. Flea market tables are $4.00 on a first-come basis, and setup will be 6:00 pm to 1:00 am on Saturday and 6:00 am to 7:45 am on Sunday. Talk-in on 146.13/.73, 146.52, and 223.10/24.70. For further information, contact Terry Evans WD9HQH, 522 S. Brotherton, Muncie IN 47302, or phone (317)-282-0615.

FREETOWN MA
MAY 23

The Fall River Amateur Radio Club will hold its flea market on Sunday, May 23, 1982, from 10:00 am to 4:00 pm at the American Legion Hall, Freetown MA. Admission is $1.00 and flea market spaces are $7.00 in advance or $9.00 at the door (the table price includes 2 admissions). Free coffee will be available. Talk-in on 147.63/.03 and .52. For space reservations, send a check payable to Fall River Amateur Radio Club to Ann M. Carro KA1DNB, 652 Old Colony Terrace, Tiverton RI 02878.

GEORGETOWN IL
MAY 23

The 13th annual Danville Area Hamfest will be held on May 23, 1982, at the fairgrounds in Georgetown IL. The gates will open at 6:00 am. Adult tickets are $2.50 in advance and $3.00 at the gate; children under 14 years of age will be admitted free. There will be a free outdoor flea market area (please bring your own tables, chairs, and power cords). The indoor area will be available at additional cost. Overnight camping, with or without water and electrical hookups, is $5.00 per vehicle per night. Activities will include door prize drawings, family entertainment, forums, and much more. Refreshments, free coffee, and free parking will be available. Talk-in on 146.22/.82 and 146.52. For more information on tickets and/or tables, contact Wendell Lyons KA9AYS, Hamfest Chairman, 903 Polk Street, Danville IL 61832 or phone (217)-431-2124.

PITTSBURGH PA
MAY 23

The 28th annual Breeze Shooters Hamfest will be held on May 23, 1982, from noon to 5:00 pm at the White Swan Park, Rte. 60 (Parkway West), near the Greater Pittsburgh International Airport, Pittsburgh PA. Registration is $2.00 or three for $5.00. Activities are a free flea market, prizes, a CW contest, and a family amusement park. Sheltered tables for vendors are available by advance registration only. Talk-in on 146.28/.88 or 29.0. For further information, contact Joe Kyler K3SJD, 4430 Evergreen Road, Pittsburgh PA 15214, or phone (412)-931-2756.

PARAMUS NJ
MAY 23

The Bergen Amateur Radio Association will hold a Swap 'n Sell on May 23, 1982, from 8:00 am to 4:00 pm at Bergen Community College, 400 Paramus Road, Paramus NJ. Buyers will be admitted free. There will be tailgating only and spaces are $3.00 (bring your own tables). For more information, contact Jim Greer KK2U, 444 Berkshire Road, Ridgewood NJ 07450, or phone (201)-445-2855.

FREMONT OH
MAY 23

The Ohio Radio Club and the Ottawa County Amateur Radio Club will hold a hamfest on May 23, 1982, at the fairgrounds in Fremont OH. Dealers may set up at 7:00 am and gates will open at 8:00 am. Advance tickets are $2.50 and $3.00 at the door. Talk-in on .31/.91 and .52. For table reservations and tickets, send an SASE to John Dickey W8CDR, 545 N. Jackson Street, Fremont OH 43420.

WEST FRIENDSHIP MD
MAY 30

The Maryland FM Association will hold its annual hamfest on Sunday, May 30, 1982, from 8:00 am to 4:00 pm at the Howard County Fairgrounds, West Friendship MD (about 30 miles west of Baltimore). Admission is a $3.00 donation, tailgating is $3.00, advance reserved tables are $6.00 each, and tables at the hamfest will be $10.00. Talk-in on 146.16/.76 and .52. For more information, write MFMA Hamfest Committee, Post Office, Harmans MD 21077. For table information and reservations, contact John Elgin WA3MNN, 5495 Apt. 2, Harpers Farm Road, Columbia MD 21044, or phone (301)-596-3741.

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received two months prior to the month in which the event takes place.

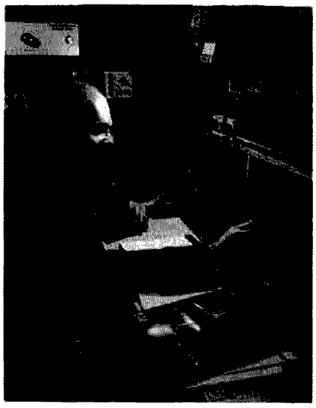
W2NSD/1 NEVER SAY DIE

editorial by Wayne Green



HOOKED

You know, after over forty years of hamming I still don't know exactly what it is that grabs the interest of a teenager and turns him from a normal rotten kid into a raving electronic maniac. I'm told by the doddering grey-bearded old-timers who have taken over most of the ham clubs in the country that youngsters are exposed to the whole world on television and thus find little exciting about talking to weird places.

Hmmm. I'm not convinced. No, amateur radio didn't gradually die off. It was killed with one blow back in 1963. Before that it had been growing at 11% per year for 17 years, right on up through the evolution of television. TV never even slowed it down.

My first exposure to amateur radio must have made a strong impression, because after 50 years I still remember it. Yep, sonny, I was a shaver of ten and while visiting the best friends of my grandparents in Bethlehem, New Hampshire, I met Harry Stevenson W1CUN. His mother, along with Johnny Macauley, ran the Valley View Inn. That was back in the heyday of hotels in Bethlehem. . .30 hotels and 100 rooming houses, the billboard at the entry to town said.

Harry was sitting there laconically talking on a 75m rig. . .a breadboard construction with a big copper tube final coil. He didn't pay a lot of attention to the visiting kid. It didn't occur to me, at ten, that I might ever be able to understand the wizardry of that mass of wires and tubes.

Like a time bomb ticking away, that experience lay hidden, waiting for the spark of puberty to set it off. By 14, I was already familiar with the excitement of the police calls at the top of the broadcast radio dial. Then all it took was an exposure to a fantastic radio my grandfather in Littleton, New Hampshire had. . .with a shortwave band on it! Wow! There were all those foreign broadcast stations. . .and a myriad of hams. I was a roly-poly kid, but the family still had trouble tearing me away from the twenty-meter ham band to eat.

It was at just this juncture that some fiend dumped a box of radio parts in my lap one Sunday at church. Most of the parts were brand new and in their original cartons, so I couldn't just throw them away. Oh, I tried to sell them to the local radio repairman (now gone the way of the ice man), but he sneered at the parts as antiques. *Popular Mechanics* had a radio construction project each month, many of them using parts just like those in my collection, so I put together a radio in an old cigar box. . .and unfortunately it worked. I was hooked.

HOME-BREW CONTEST WINNERS

- 1st place, $250 prize: "Smart Squelch for Single-Sideband Receivers" by Frank Reid W9MKV and David Link W9YAN, both of Bloomington IN.
- 2nd place, $100 prize: "Six-Meter Double-Sideband QRP Transmitter" by Larry Jack KL7GLK of Annapolis MD.
- Honorable mention, $50 each: "MB-1 Function Circuit" by Mike Strange WA2BHB, Pine Hill NJ, "Splattometer" by Penn Clower W1BG, Andover MA, and "Weather Converter for Your Two-Meter Rig" by Paul Danzer N1II, Norwalk CT.

We're sure you have heard it said that "hams are not building anymore; they're just appliance operators." Well, *73*'s Home-brew Contest proves that rumor to be baloney. We were literally buried with entries. The winning projects show that hams are not only building, but that they are still innovating, too.

Our editorial staff burned the midnight oil in early April, choosing five finalists from more than 100 entries. The winners were then picked by three of *73*'s veteran home-brewers: AG9V, K1XR, and W1XU.

The Home-brew Contest winners will be published in future issues of *73*. In the meantime, keep your soldering iron hot—*73* is having another contest. This time there will be a $50 limit for the project's parts.

$$ HOME-BREW II CONTEST $$

Between now and October 1, we'll be looking for articles describing the best home-brew projects in the land for under $50. All useful projects will be published in *73*, and the cream of the crop will share $500 in cash prizes. Top prize in the contest is $250, with $100 going to the second place project and $50 to each of three honorable mentions. These prizes are over and above the payment that all authors receive for having their articles published in *73*.

Contest Rules

1. All entries must be received by October 1, 1982. To enter, write an article describing your best home-brew construction project, and submit the article to *73 Magazine*. Any construction article received before the October 1 deadline is automatically entered in the contest. Any entries for the first Home-brew Contest which meet the $50 requirement for Home-brew II will be automatically entered. If you haven't written for *73* before, please send an SASE for a copy of our author's guide.
2. The total cost of the project must not exceed $50, even if all parts are purchased new. Be sure to include a detailed parts list, with prices.
3. All parts used in the project must be available to the average radio amateur or electronics experimenter. To be on the safe side, include sources for any unusual components.
4. Projects will be judged by the *73* technical staff on the basis of usefulness, reproducibility, economy of design, and clarity of presentation. The decision of the judges is final.
5. All projects must be original, i.e., not previously published elsewhere.
6. All rights to articles purchased for publication become the property of *73 Magazine*.

Send your entries to:

Home-Brew II Contest
73 Magazine
80 Pine Street
Peterborough NH 03458

Winners will be announced in the December, 1982, issue of *73*. Have fun!

Build This Digital Vfo

—a microprocessor makes it simple

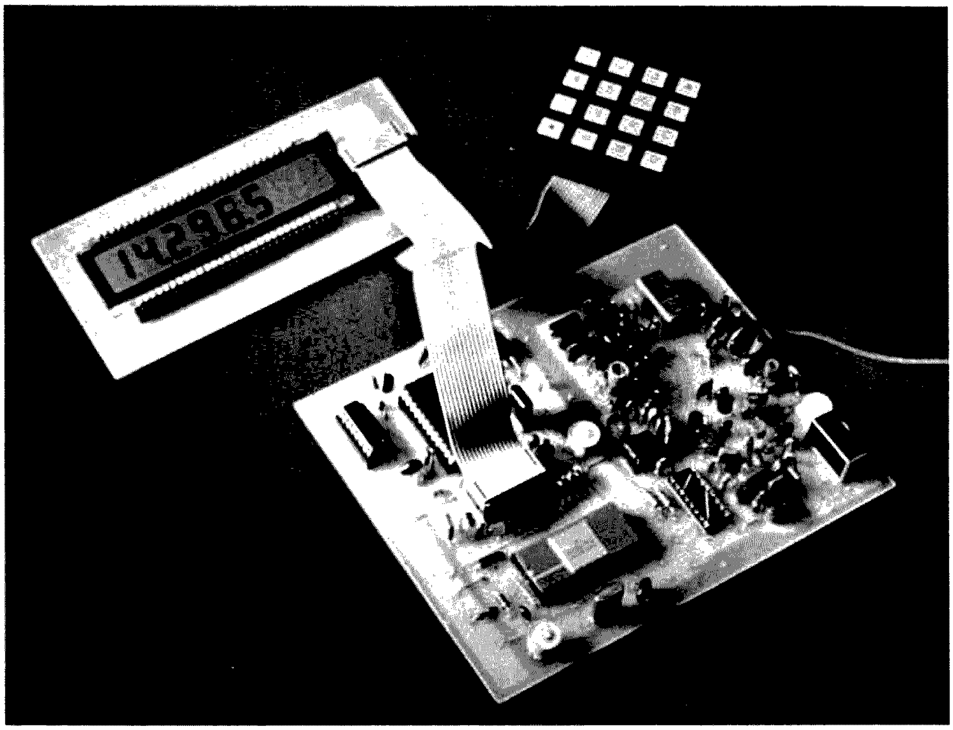
Ed. Note: The MC6805T2L2 microprocessor IC used in this project must be ordered directly from Motorola. Send a money order only (no checks) for $11.50, payable to Motorola, to: Tim Ahrens, Motorola, 3501 Ed Bluestein Blvd., Austin TX 78721, Attention: Mail Stop L-2787.

This article describes a microprocessor-controlled vfo which may be used as a remote vfo for existing stations or incorporated into new radio-system designs. The vfo features ten battery-backed-up memories, keypad entry of frequency, up/down scanning, a real-time clock, plus a liquid crystal display.

As a remote, the vfo tunes from 5 to 6 MHz in 100-Hz increments and is directly compatible with radios which use a 5-to-5.5-MHz internal vfo (e.g., FT-107, FT-707, etc.). If using one of these radios, only small modifications within the radio are required to allow the remote vfo to change bands at the touch of a finger!

Microprocessor Selection

The vfo is designed around Motorola's MC6805T2 microprocessor. Within this multi-function chip (now called a microcomputing unit—MCU—because of all the integrated functions on board), I/O plays a very important part. This is the portion of the MCU which does the actual communicating with switches, LEDs, bells, and whistles. The MC6805T2 MCU used in this project (we will refer to it as the "T2") has a small amount of RAM, ROM (2.5 K bytes), a timer, parallel I/O lines, and one other feature that makes it ideal in the radio environment—a built-in frequency synthesizer. A block diagram of the synthesizer is shown in Fig.1(a); Fig.1(b) is a block diagram of the entire vfo.



The vco signal which is fed back into the T2 may have an amplitude as low as one-half volt and be as fast as 16 MHz. With external prescaling, the vco frequency may be considerably higher. However, any external prescaling will multiply the step size by the prescaling factor.

In addition to its on-chip synthesizer, the T2 contains enough ROM to hold all the software needed for the vfo control program. In fact, the T2 with the vfo program in ROM is available from any Motorola distributor.

An alternative to the T2 is the MC68705P3 MPU. The P3 is very similar to the T2 except that it requires an external synthesizer and it contains on-board EPROM instead of ROM. The EPROM on the P3 is user-programmable, so you should use the P3 if you need a control program other than the one avail-

able in ROM on the T2. See the box for further information on programming and use of the P3.

The circuit-board layouts given in this article can be jumpered for use with either MPU. The figures and text explain where differences occur. For those who prefer not to etch their own boards, a source for boards as well as components is given in the small box.

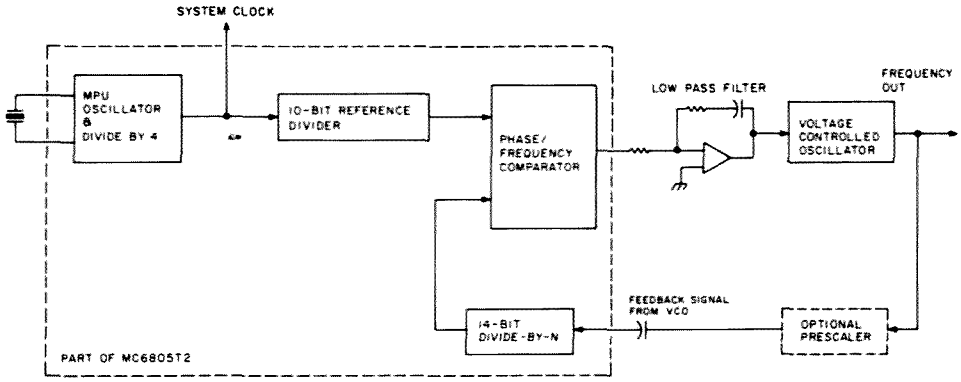


Fig. 1(a). Block diagram of synthesizer on MC6805T2 MCU chip.

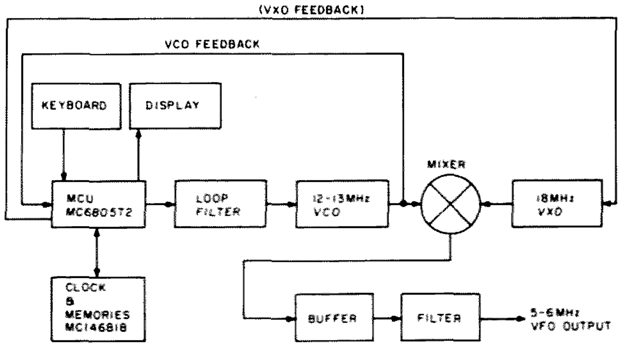

Fig. 1(b). Block diagram of entire microprocessor-controlled vfo.

Using the Vfo

Upon power-up, the MCU reads the last-entered frequency from the RAM on board a battery-backed-up MC146818 clock chip, enters it into the synthesizer, and displays it. If powering up from a "dead" system (no battery backup), garbage will be both displayed and entered into the PLL system.

After the power-up sequence is completed, numbers for a different frequency may be entered via the keyboard. When the display shows the frequency desired, depress "enter" and the PLL system will be set up. By entering the frequency in this manner, it is also stored in RAM so that if a power failure should occur, the correct frequency will be read from the battery-backed-up system and the PLL restored.

If the displayed frequency is to be stored into memory for later recall, press "memory" followed by a digit, 0-9. To retrieve a previously stored frequency, press "recall" followed by the desired digit. All of these memories have battery backup.

If you want to move up in frequency, press and hold the "up" button. If you want to go up fast, press and hold the "fast" button at the same time. The frequency will go up until it reaches XX.999.9, at which time it will roll over to XX.000.0. To make the system go down in frequency, the same procedure may be followed using the "down" key.

To set the time, press "recall" followed by "memory." At this time, the display will show EEEEEE, signifying that the time may now be entered. Enter the time in 24-hour format, and when satisfied with the display, press "enter." At this time, the data will be placed into the clock chip's registers and time-keeping will commence. When "enter" is depressed, the frequency that was on the display before setting the clock will be restored to the display. The actual PLL systems are not disturbed by entering into either this mode or the time-display mode.

To display the time with an update every second, press "recall" followed by "enter." You may exit this mode by pressing any key, which will return the display to the previous frequency.

As you can see, the combination of the MC6805T2 MCU and the MC146818 clock chip provides the radio designer with capabilities that far surpass the previously acceptable methods of frequency control. The 6818 may be omitted, but the clock feature, stored frequencies, and the battery backup of them will also be deleted.

Vfo Circuit Design

The rf circuitry I used is given in Fig. 2, while the MCU and its peripherals are shown in Fig. 3.

As the MCU's minimum step is 1 kHz, some method of refinement must be incorporated because 1 kHz is not adequate resolution in the HF bands. By using four of the I/O lines from the MCU for a voltage-summing network, 100-Hz stepping increments may be realized. The output of the summing network is used as an "offset" voltage to shift the frequency of the vfo. Because the frequency will be locked (basically to itself), changing the main vco frequency would achieve nothing. There are, however, two methods of

PARTS AVAILABILITY

The varactor diodes (D2 and D3) and most of the integrated circuits used in this project are Motorola devices and are available from Motorola distributors. In many parts of the country, Hamilton-Avnet Electronics is a source for these parts. Excluding the LCD unit, a set of ICs for this project should cost between $45 and $70, depending on which microprocessor you select for your version.

The MD108 double-balanced mixer is available for $12 postpaid from ANZAC, 180 Cambridge St., Burlington MA 01803. A good selection of coils and forms can be found at RADIOKIT, Box 411S, Greenville NH 03048.

Parts, as well as circuit boards, are also available from Conversion Dynamics, 2218 Old Middlefield Way, Suite N, Mountain View CA 94043. Their version uses a double-sided PC board and an LED rather than LCD frequency display. Write to them for more details.

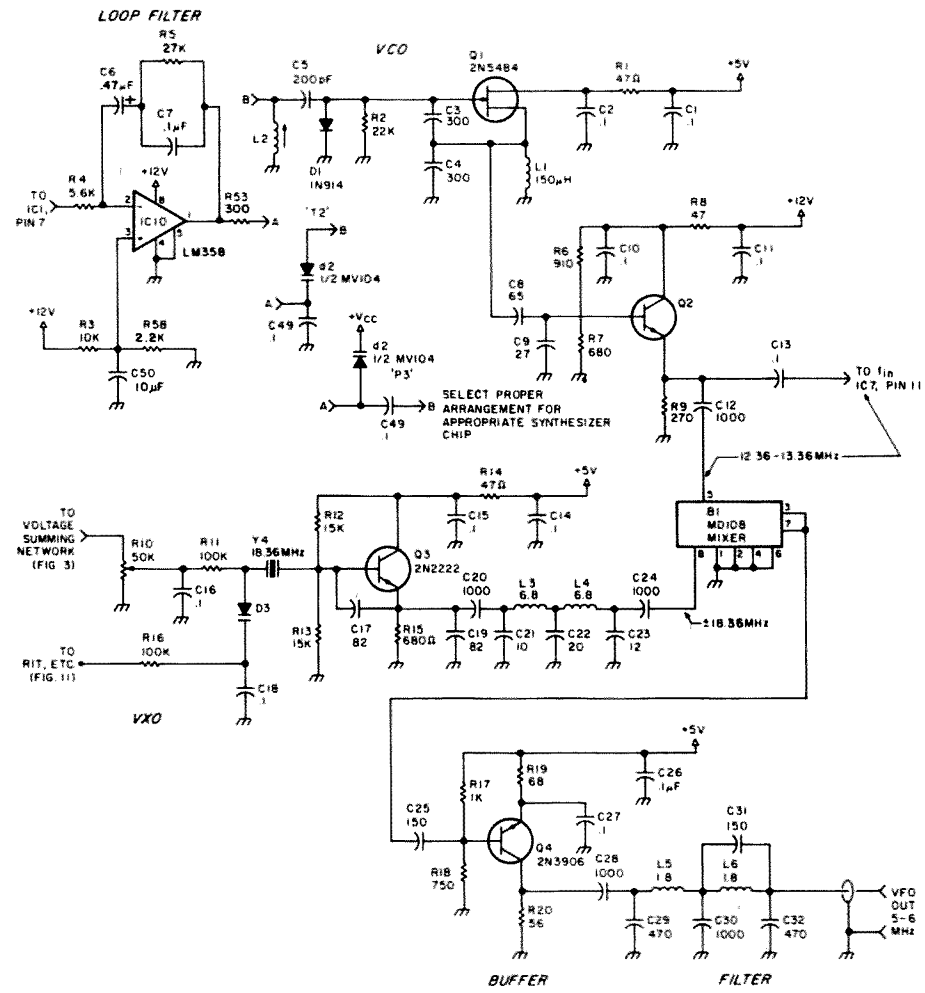

Fig. 2. Rf circuitry of vfo.

changing the frequency which would not affect the PLL system itself: Shift the reference frequency, or use an auxiliary variable crystal oscillator (vxo) and then mix the two frequencies together.

The first method was tried initially, but due to the low frequency of the crystal, I could not pull the oscillator far enough off frequency to provide the 100-Hz shift and still have provisions for RIT. So the second method, of an auxiliary vxo, was tried. The main vco tunes from 12.36 to 13.36 MHz and is then mixed with 18.36 MHz from the vxo to provide the necessary 5-to-6-MHz signal. This method of shifting through 100-Hz steps may seem a bit crude, but several commercial transceivers use this method. In fact, Icom's IC-730 uses this method to generate 10-Hz steps! Fig. 4, a spectrum analyzer photo, shows the actual vfo output.

The 18.360-MHz vxo crystal (Y4) was chosen because I had one; it is a 146.88-MHz transmit crystal for an HT-144. Either of two crystals may be used in the oscillator. An 18.360-MHz or an 18.860-MHz crystal may be selected by a jumper and a pullup/pulldown resistor on pin 27 of IC1 (see Fig. 3). The vco must be adjusted for the crystal you choose.

If a different frequency range is to be covered by the vfo, the frequency of the vxo crystal must be changed, and appropriate modifications in the filters should be made. From this, it may be seen that almost any frequency may be generated from the vfo by simply changing the vxo crystal.

The MCU and Clock Circuit

A version of the MC6805T2 is available from Motorola which already contains in ROM the program necessary to function as a vfo. This part is called an MC6805T2L2. The L2 signifies a specific program within a ceramic part, in this case, the vfo software. The MCU is used to gather data from the keyboard and execute any function which is "called up." The lines used for I/O are represented by PA0-PA7, PB0-PB7, and PC0-PC2. Port A is used for both the keyboard and interface to the MC146818 clock chip. In this application, the clock chip is battery-backed-up, and when powered down draws only 300-400 microamperes from a four-and-one-half-volt source.

The B port is used to control the four bits of the voltage-summing network plus the read/write and control lines of the clock. The C port is used to control the clock and data lines of the liquid crystal display (LCD). Only two crystals are required in this part of the vfo—a 4.096 MHz for the MCU, and a 4.194 MHz for the clock chip. These frequencies are divided down by their respective hosts for internal timing.

All of the peripherals with the exception of the 6818 are serial devices. This means that the digital data which goes to each part requires only two lines, a data line and a clock line. In the MCU environment, I/O lines are at a premium; that is why data lines are common to all parts and only the clock or enable lines are separated from the rest.

The Display

The display portion of the system uses the MC145000 multiplexed LCD driver and an 8-digit LCD, although only six digits are used.

The MC145000 requires a total of four lines—power, ground, clock, and data. This means that the display may be located away from the main PC board. This makes for a lot easier construction of the total project! Since this is digital data on two of the lines, use no more than about a foot of cable. Current consumption is quite low with this CMOS device—about 75 microamperes. As data is shifted into the 145000, every 8 bits will shift over one character from left to right. Even if only the right-hand-most digit is to be

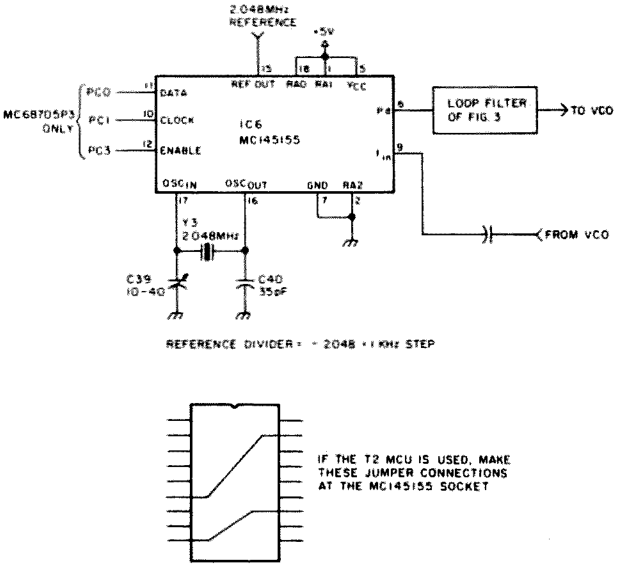

Fig. A. Using the MC145155 CMOS synthesizer.

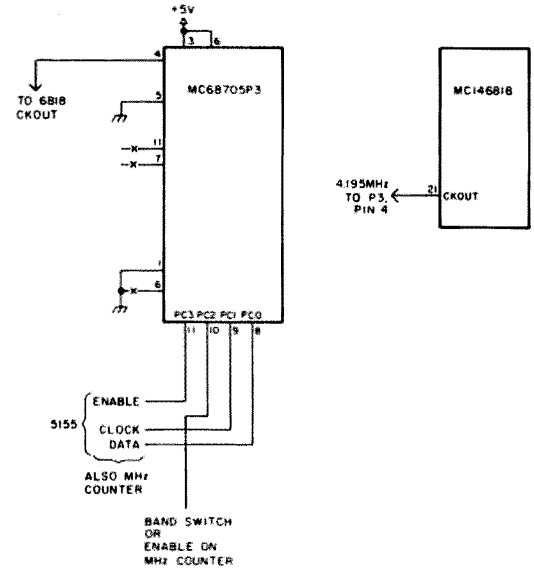

Fig. B. 6805 T2 vs. P3 differences.

Using the P3

Although designed for the MC6805T2, the vfo software was given the capability of using the MC68705P3 as a host MCU. This MCU is identical to the T2 with the following exceptions: • The P3 does not contain a PLL. • The P3 is an EPROM-type part which programs itself.

In the early stages of the design, a T2 was not available and a "simulation" was made by using a P3 and an MC145155 CMOS synthesizer. If changes to the program are desired, you may use a P3 plus an MC145155 CMOS synthesizer to simulate the T2, as shown in Figs. A and B. This allows you to use the same basic core of the program and add enhancements that might be useful.

The actual software listing for the system is available from me on receipt of a large SASE plus $3.00 to cover copying costs. It may be entered into an MCM2716 2K by 8 EPROM for programming of the MC68705P3. Fig. C is a schematic for the programmer.

The MC68705P3 MCU has the capability of programming itself. By adding only one additional part (MC14040B), the P3 can read data from a 2K by 8 EPROM and program itself from it. Two LEDs are used, which signify that the device has been 1-programmed, and 2-verified.

Because the hardware required to program the P3 is so small, even the casual amateur/hobbyist may build a programmer to take advantage of the MCU's capabilities.

Either the T2 or the P3 with the MC145155 can be used with the circuit board presented in this article. If the T2 is used, the MC145155 is not needed and two jumper connections should be made at the MC145155 socket. See Fig. A.

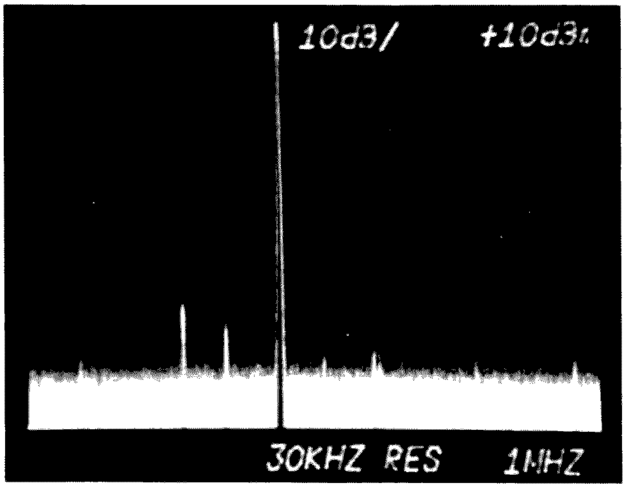

Fig. 4. Vfo output displayed on spectrum analyzer.

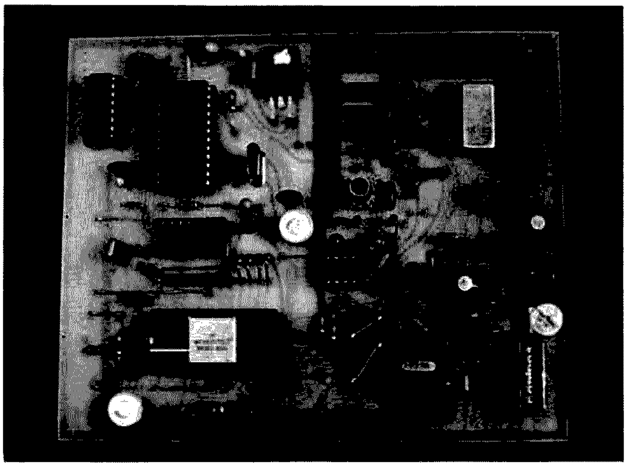
The Real-Time Clock

The MC146818 is a new device which not only has a real-time clock in it, but also contains 50 bytes of CMOS RAM. This makes the device an excellent choice, since data in the RAM may easily be saved in a power-down condition.

The 6818 has a clock generation circuit on chip which requires only a crystal, resistor, and two small capacitors to generate not only the time clock source, but also a clock signal for the rest of the system if desired. If the crystal mode is not chosen, the 6818 may be driven with an external frequency of 4.195 MHz, 1.048 MHz, or 32.768 kHz. An internal register tells the 6818 which frequency it is on. I have found that the 6818 draws less power when operating at the lowest frequency—32.768 kHz. In fact, by using an MC14069 inverter as a crystal oscillator at 32.768 kHz, less power is used than by using a 4.194-MHz crystal on the 6818! As with most parts of this type, the faster the clock, the more current required.

The MC146818 may be set up in a 12/24-hour type mode, plus alarms which may be set to interrupt at any time, including every hour, minute, or second. As shown in Fig. 6, there are 14 registers required to set up this data, and the entire memory map looks like 64 RAM locations.

Although the MC146818



Main circuit board, using the MC6805T2L2 MPU. If the alternate "P3" MPU is used, then the socket with jumpers at lower center would be replaced with an MC145155P synthesizer chip. The empty socket at left is for the plug-in cable to the keypad. At upper right is a metal can containing the double-balanced mixer.

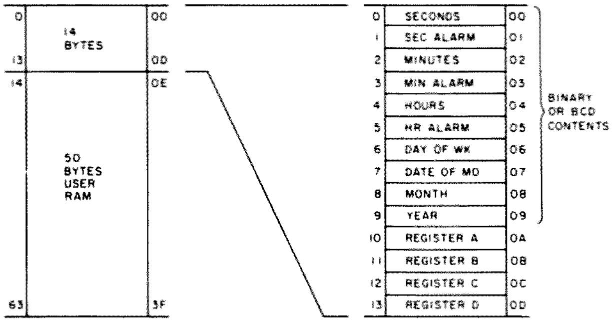


Fig. 6. Registers of the MC146818 clock chip.

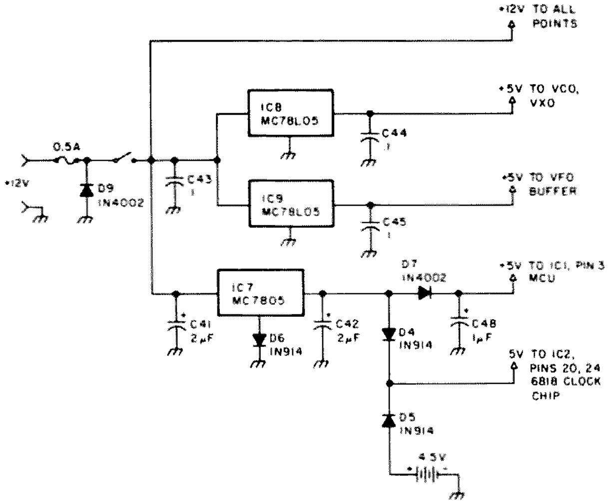

Fig. 7. Power supply. The regulated 12 V dc which drives this supply can often be derived from your transceiver. Otherwise, a simple 12-V-dc, 1-A source should be constructed.

clock chip is not designed to have any I/O pins, there is one way in which a single output bit may be "constructed." The SQW pin is a software-programmable clock output pin whose frequency is a derivative of the 6818's clock. The internal register which controls the frequency of the SQW pin can not only change the frequency of the pin, but it may also turn it off. By setting the frequency of the SQW to some relatively high frequency (it is not really that important) and providing some external filtering, when the clock is on, the output of the filter represents a "one" condition, and when off, represents a "zero" condition! This provides an extra I/O pin.

Power Supply

To supply the MC146818 with voltage both when the main system is off and on, there need to be a few smarts involved. See Fig. 7. The trick required is to use D6 to initially raise the 5 volts from IC7 one diode drop higher (.7 V), then drop the supply voltage (Vcc) to both MCU and 6818 by separate diodes (D4 and D7). This ensures that both parts are operating at basically the same voltage. For battery-backup operation, D5 is inserted from the plus lead of the battery to pin 20 of the 6818. This isolates the batteries from the rest of the system and doesn't allow any current to flow back into them when the main Vcc is on. If you are using nicads, a resistor of appropriate value could replace the diode to allow charging during on time. The value of this resistor is of little consequence to the 6818 when the main power is off because the current consumption of the 6818 is so low.

In addition to the voltage differential, there is another consideration regarding the chip enable (CE) line of the 6818. When the system is powered down (main power), the CE line of the 6818 should be brought high to ensure that the part is deselected. This is easily accomplished by using a transistor (Q5 in Fig. 3) in the classical inverter style. The base is tied to the MCU Vcc (through an appropriate resistor), and the collector resistor is tied to the 6818 Vcc. When the system is on, the collector is low, enabling the 6818, but it goes high when the system gets turned off.

The Keyboard

Because I/O lines are so valuable, each one commonly is given more than one function. Of course, every effort has been made to keep the number of lines required to a minimum (by using serial-type devices), but there are instances where large numbers of I/O pins are required. For instance, the 4 × 4 keypad requires eight lines just to decode the proper key. Yes, a two-to-four decoder could have been placed external to the MCU which would free up two additional lines, but it also would have required an external device to perform that function. The system designer must make the decision here. In this

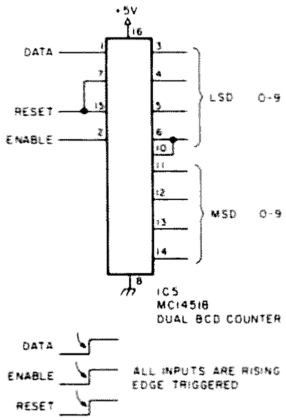

Fig. 8. MHz-counter option.

case, I chose to "multiplex" the data lines for the clock on the same I/O lines as those required for the keyboard.

The way the software works, immediately after a key is released, e.g., the "enter" key, the data direc-

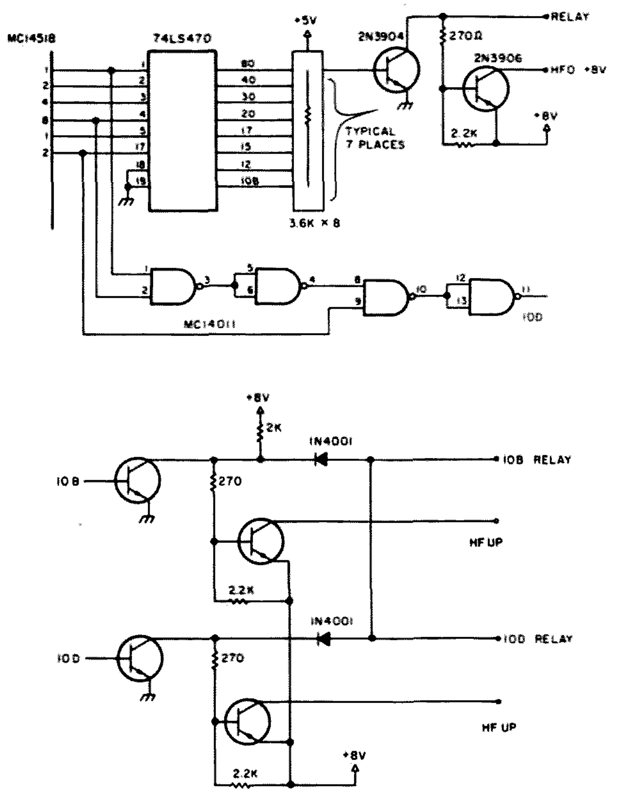

Fig. 9(a). This circuit provides automatic bandswitching for the FT-707. Alternative connections may be required for the FT-107 or other radios. Be sure to place the FT-707 bandswitch in the unused position when this hardware is connected.

tion registers in the MCU are set up to talk to the 6818. Data is then transferred to the 6818's RAM. As soon as the data transfer is complete, the MCU is reconfigured for inputs from the keyboard. The actual transfer time is so short (<300 μs) that no matter how hard the operator tries, he cannot hit another key before the data transfer is complete. While in the time-display mode, once every second an interrupt is generated. As soon as the MCU recognizes this interrupt, the MCU reads the time from the 6818 and displays it. As soon as that data is read, the MCU is reconfigured for a keyboard entry. The rest of the one-second period, the MCU is waiting for a button to be pushed. The amount of time required to read the time (< 50 μs) is the only time that depressing a key could possibly disturb the actual data read. But since any key depression would be greater than 20 ms, the incorrect frequency would be displayed, then immediately jump out of the time-display mode and redisplay the last frequency.

Band and Mode Switching

For the vfo to be used conveniently with a multiband transceiver, some method must be provided to tell the external PLL system which MHz segment it is on. This function is implemented as follows.

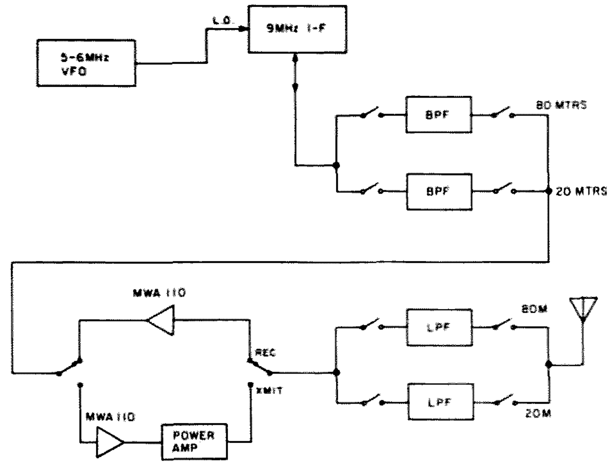

Fig. 10. Block diagram of a complete single-conversion transceiver controlled by the microprocessor vfo.

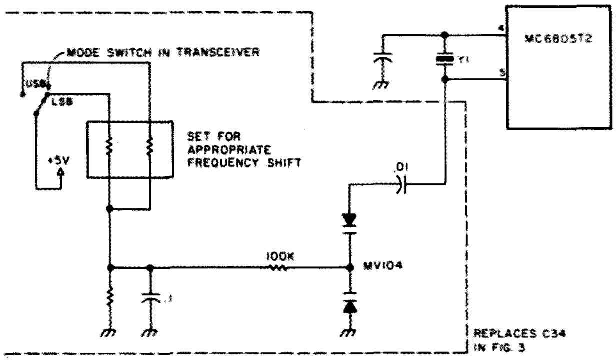

Fig. 11. Mode switching for rigs which display actual operating frequency (not carrier frequency).

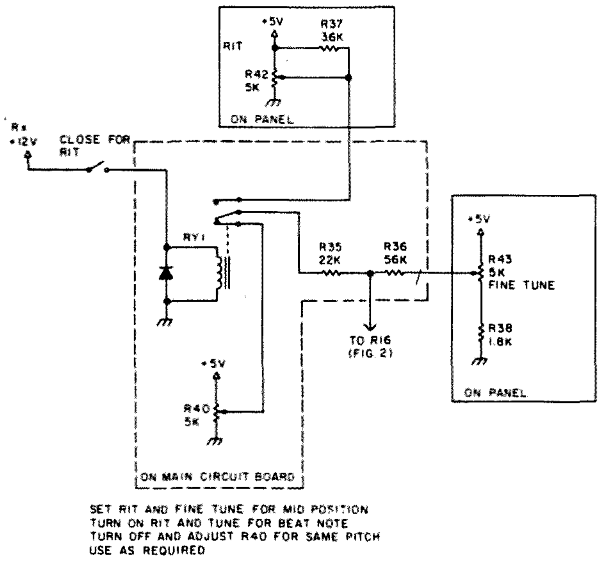

Fig. 12. Adding RIT and fine tuning to the vfo. Most of these components mount on the main circuit board.

Whenever the frequency is sent to the on-board synthesizer, the two most significant digits (MHz) are sent serially to the data pin (PC0). If operating on 5 MHz, the sequence of events is: (1) set up the 5-6-MHz synthesizer, (2) pulse the SQW pin of the 6818 (resets the external counter), (3) set the clock enable pin (allows clock line to increment counter), (4) send out five pulses (for 5 MHz), (5) clear the clock enable pin, and (6) continue with program.

The circuit for a simple decoding scheme using the MC14518 dual-BCD counter is shown in Fig. 8. One use for the outputs from the counter is to provide automatic bandswitching.

References were made earlier to bandswitching on an FT-107 or FT-707. Fig. 9(a) shows how it may be accomplished. By taking the outputs of the binary decoder of Fig. 8 and running them into a 74LS470 Programmable Read Only Memory (PROM), certain combinations of frequencies may be turned into levels which may drive circuitry to change bands. The PROM must be programmed as per Fig. 9(b). Unlike older transceivers, the FT-107 and 707 do not use a bandswitch which runs the entire depth of the rig. The actual switch is only a double-pole type which switches relays within the radio. By placing this switch in an unused position and adding appropriate drivers, the remote vfo can switch bands, too!

I originally used this vfo with a simple home-brew transceiver that operates on both 80 and 20 meters, with no external heterodyne oscillator. This single-conversion radio provides an excellent "simple" radio, with the T2 controlling everything, including the bandswitching of the filters. Fig. 10 shows a block diagram of this radio.

The vfo provides the actual frequency selection, with the display presenting the operator with the carrier frequency. If you are upgrading a standard radio such as Heath or Collins where there was an analog method of readout, there will be no problem in conversion. But if you are already using a digital readout that displays not the carrier frequency, but the actual "talk frequency," then an additional modification must be made to the system. This mod will shift the reference oscillator by 1.5 kHz, either up or

MODE (PC2,1,0)	DISPLAY	VFO FREQUENCY	PURPOSE
000	3.0000	5.0000	INVERTED 80-20M

down, depending on which sideband you are on. By tapping off the mode switch in the rig, the frequency may be shifted automatically.

Fig. 11 gives an example of how this may be accomplished. In this diagram, a voltage divider is switched, depending on what mode the radio is in. Of course, an additional position on the switch may be used for CW, AM, etc. This mod must be made if using the vfo as a companion for another digital rig which uses a 5-to-6-MHz vfo.

RIT

In almost every rig that I've owned, receiver incremental tuning (RIT) was a must for operating convenience. This vfo provides the user with not only a RIT control, but also a fine-tuning adjustment for stations between the 100-Hz resolution of the vfo. The foil pattern for all RIT components with the exception of the panel controls is on the PC board, including the relay used to switch it in and out. Fig. 12 illustrates how the RIT is implemented. (Thanks to Yaesu for their design.)

Construction and Alignment

I recommend that the vco be built first. This is the most difficult portion of the vfo, and the rest comes easily once this is completed. After the vco is built, check its frequency range by turning the slug in coil L2. It should encompass the 12.36-13.36-MHz range required. After this has been built, build the rest of the rf section (18-MHz vxo and filters). Only after you have 5 to 6 MHz coming out of the filter stage should you proceed with the digital section. Depending on which parts you are using (T2 or P3), select the appropriate jumpers and install the rest of the parts. The 6818 fre-

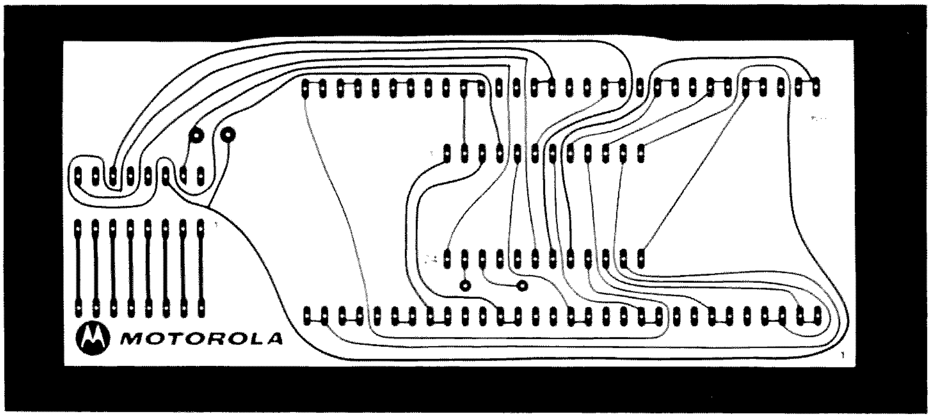

Fig. 14. Display PC board (foil side).

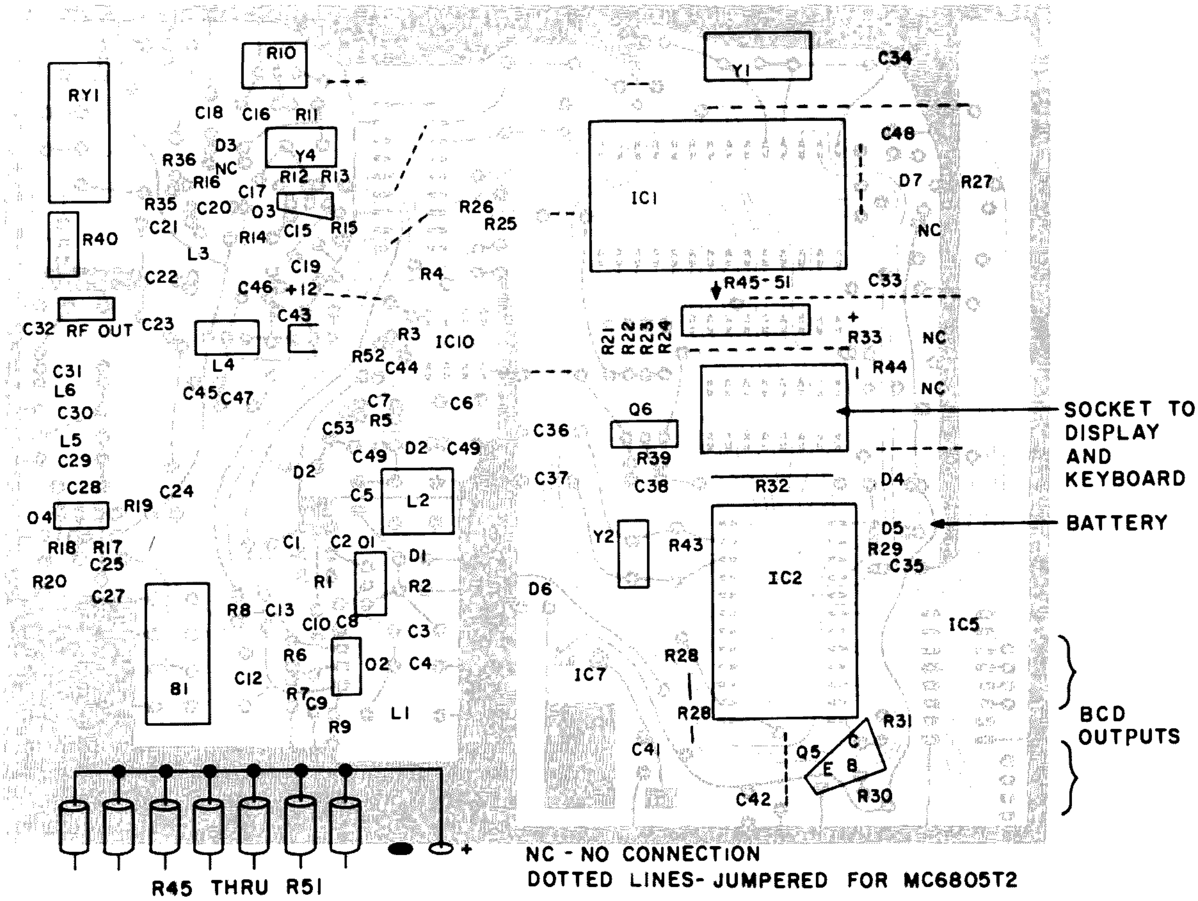

Fig. 15. Component placement, main board.

quency may be adjusted by placing a counter on pin 21. Trimmer C36 should be adjusted to read 4.194308 MHz. If you cannot bring it exactly on frequency, some adjustment of fixed capacitor C37 may be required.

If you are using the P3, the frequency of the MC145155 may be observed on pin 15 of the part. Adjust C39 for 2.048 MHz. If using the T2, use a low-capacitance probe on pin 5 of the MCU and adjust C34 for 4.096 MHz. If, upon power-up, the unit appears dead, it is time to borrow an oscilloscope to do some checking. First, check the jumpers and power supplies. Next, check to see that the oscillators are functioning properly.

If the unit seems to operate properly but the vco will not track, be sure that the loop filter is properly built and that there is a feedback frequency back to the PLL. Also, check for the obvious solder short.

Figs. 13 and 15 are the PC layouts for the vfo and display, respectively. Figs. 14 and 16 show component placement.

Table 1 lists the available modes of the vfo system. The modes are selected by strapping I/O pins PC0, PC1, and PC2 to either +5 V or ground through 15k resis-

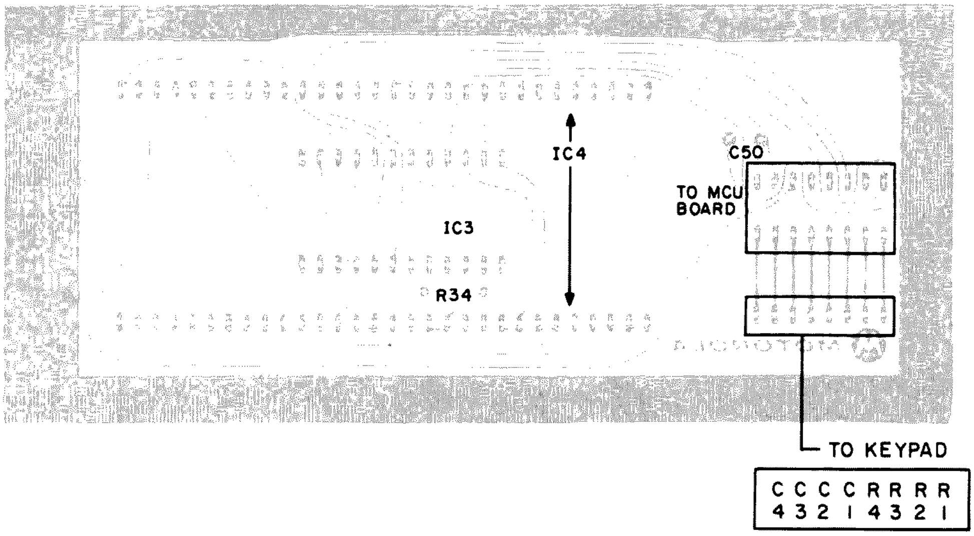

Fig. 16. Component placement, display board. Driver chip fits under display unit, on the same side of the board. Display unit is elevated above the board by segments of high-profile IC sockets (see photos).

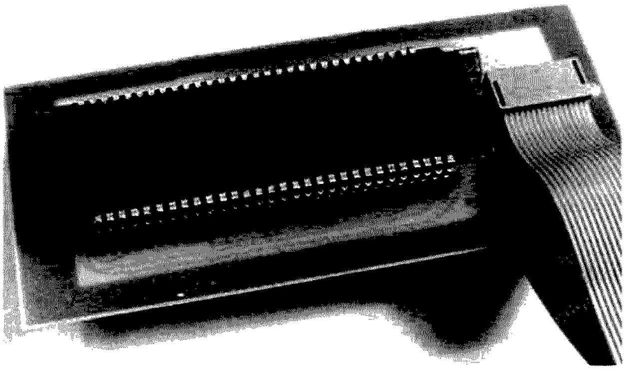

Display board. The liquid crystal display (LCD) unit plugs into a home-brew socket composed of pieces of two 40-pin IC sockets.

tors. In the first column of the table, a 0 indicates the pin is connected to ground, while a 1 means the pin is connected to +5 V. The table shows the available modes vs. the frequencies produced. Also included are the purposes behind each mode. The mode is read at reset time on PC0, PC1, and PC2.

Getting the Parts

Approximate costs of the high-value items of the project are:

- MC6805T2L2—$12.00-15.00
- MC68705P3—$50.00 (not needed if the T2 is used)
- MC145155—$7.32 (not needed if the T2 is used)
- MC146818—$10.00
- MC145000—$12.49
- 8-digit LCD—$26.40

The MC6805T2 containing the program used for this project is an evaluation part under the number MC6805T2L2 (ceramic case) and is available from any Motorola distributor, as is the MC68705P3, the alternative MPU.

The liquid crystal display (GE part LXD69D7R09) is available from any GE distributor (Hamilton Avnet, etc.).

My heartiest thanks go to Helge Granberg and Mike Pendley, who provided me with some necessary rf savvy, and Ulrich Rohde, who gave me some insights into PLL system design. ■

Surviving the Unthinkable

—part II: some practical ideas

In part I, I talked about the *idea* of emergency communications after a nuclear attack and the benefits the Amateur Service might provide. In this part, we'll talk about specific steps that each of us can take. First, though, let's set the stage:

Imagine this situation for a moment: The most incompetent of operators walked into your shack and for a fraction of an instant connected your receiver's antenna terminals to a high-voltage distribution line. The result was a 40-kV, 1,000-Amp shock to the input of your receiver. There wouldn't be very much left of your sensitive input circuits, to say the least.

This sounds like an impossible situation. I only wish that it were truly impossible. But in today's crisis-oriented world, the situation is indeed within the realm of possibility. The 40-kV shock is what civil-defense experts say would be the result of a nuclear blast in the vicinity of most any piece of unshielded wire, including telephone wires, power lines, antennas, and feedlines. The phenomenon is commonly referred to as a nuclear electromagnetic pulse (EMP or NEMP).

This kind of pulse is so extreme in amplitude that many normal lightning protectors are useless. For example, a typical lightning pulse has about a 100-microsecond duration, with a 5-microsecond rise to its peak. A high-altitude EMP pulse can be expected to have a 1-microsecond duration and a 10-nanosecond rise to its peak. That's not enough time for many common lightning arrestors to work.

In the following pages we'll talk about some of the EMP protective measures which should be taken on your equipment. Without protection, sensitive semiconductors would be most likely to fail and put you out of business when your services may be needed most.

But, first, why should we even be concerned about protection? After all, any nuclear exchange seems to be so outrageously incompetent on the part of world leaders that it seems that it never could happen. Unfortunately, however, we've seen in the last few years that many improbable things such as revolutions, hostage taking, etc., have actually occurred.

Even though we all hope and pray that a nuclear exchange does not occur, let us not underestimate the devastating and paralyzing effects of such an exchange. Simply imagine, for a moment, a world with *hundreds of millions* of US and Russian citizens killed and *tens of millions* more severely and untreatably burned, near death, and starving. Major cities, with their sophisticated hospitals, police, telephone communication systems, radio and television stations, transportation, food distribution networks, financial centers, and manufacturing centers all eliminated—gone—not much usable left, and most likely too radioactive to approach for many years to
